Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Electrical Engineer.

A Weekly Review

OF

Theoretical and Applied Electricity.

VOLUME XVII.—1894.

(January to June.)

NEW YORK:
The Electrical Engineer,
203 Broadway.

Alphabetical Index of Contents.

A denotes Articles. **Ax** denotes Abstracts and Extracts. **E** denotes Editorials. **L** denotes Letters to the Editor.
L N denotes Legal Notes. **N** denotes News and Notes. **R** denotes Reviews of Books. **P N** denotes Patent Notes.
T N denotes Trade Notes and Novelties and Mechanical Department. An Asterisk (*) denotes Illustrations.

Page.

A

Accumulator, Chloride on Paris street railways ... *A 230
" Copper-zinc. C. J. Reed ... A 273
" " Paul Schoop. A 67, 83, 106, 157, 178, 228
" Henry ... *A 429
" litigation, Chloride ... L 165
" More about the Chloride ... L 241
Accumulators in central stations ... *A 241
" (*See also Storage Batteries*)
Acme portable testing set ... T N 172
" standard voltmeters ... *T N 194
Acoustic synchronizer for alternating machines ... *T N 59
Action of electro-magnetic radiation on films containing metallic powders ... Ax 163
Adams Electric Ry. Co. vs. Lindell Electric Ry. Co ... L N 376
" " " litigation ... L N 308
Adaptability of an Edison three-wire plant. Jas. Milne ... *A 177
Advantages of direct connected, direct current generators ... Ax 141
Advertising system, Moore electrical ... T N 523
Air-core transformers ... L 261
Allen soldering stick ... T N 335
Alternate current curves, Apparatus for taking. ... *A 325
Alternating apparatus of the Stanley Electric Co ... *A 505
" current motors. (*See also Motors.*)
" " systems, copper economy of, Chas. Steinmetz ... A 153
" " and fuses ... *Ax 492, E 494
Alternators for Niagara, Proposed 5,000 H. P. *A 232
Altoona Mfg. Co ... T N 268
Aluminum manufacture at Niagara. ... T N 40
American Association for the Advancement of Science ... N 517
" Bell Capital to be $50,000,000 ... N 119
" " Telephone Co., Fourteenth report ... N 308
" gondola ... E 159
" Institute of Electrical Engineers. N 56, 76, 166, 191, 262, 286, 346, 374, 395, 501, 551; E 413, 435, 455; A 452, 456
" Mfg. & Engineering Co ... T N 541
" Metrological Society ... N 346
" Society of Civil Engineers, Annual Convention ... N 517
" Street Ry. Association ... N 439
Ammeters and voltmeters, Queen & Co ... T N 60
Amphibious Railway ... *A 6
Annuaire du Bureau des Longitudes, 1894 ... R 395
Ansonia Electric Co ... T N 57
Antwerp Exposition ... N 249
Apparatus for the taking of alternate current curves ... *A 325
Arc lamp design ... L 144
" " for incandescent and railway circuits ... *T N 224
" lighting apparatus of the Fort Wayne Electric Corporation ... *A 528
" lights, small or subdivided ... A 431
Arcs, big opening for small ... E 234
" Enclosed high potential ... E 183
" Information on incandescent. ... L 329
Armature winding, Rushmore drum ... *T N 568
Armatures, relative advantages of toothed and smooth core ... Ax 459
Arnold system of electric power station construction ... *A 436
Ashwell and Vandergrift tubular mercury pump ... Ax 240
Austin Engineering Co ... N 38
Autograph time recorder ... *T N 462
Automatic car fender and brake ... *A 137
Ayer & Co., J. I. ... T N 40

B

Babcock & Wilcox boiler tests ... T N 464 L 495
Bacteria in telephones ... E 535
Badger, G. E ... N 56
Bain arc machine with automatic regulator *T N 421
Ball direct connected engine and Waddell-Entz generator ... *T N 196
" & Wood Co ... T N 502
" " reception ... N 311
" " vertical compound engine ... *A 368
Balloon at Antwerp, trolley ... N 483
Barclay, J. L. (*obituary*) ... 303
Barmen electric rack railway ... *A 531
Barrett and the conduit ... N 111
Barstow, W. F ... N 301
Base ball reporter, Compton ... *A 500
Battery, Imperial dry ... *T N 172, 318
" Robbins paste ... T N 146
Behavior of certain bodies in presence of electro-magnetic oscillation ... N 537
Belknap multipolar generator ... *T N 502
Bell, 110 volt, of the Electric Bell & Resistance Co ... *T N 541
Bell, Dr. Louis, on polyphase apparatus ... N 56
Bentley, E. M ... T N 221
Bergmann alternating arc lamp ... *T N 194
Berlin Iron Bridge Co ... T N 19, 80, 147
Berliner patent ... E 18, L N 538, 551
Biddle system of electric lighting for railway trains ... *A 518
Big opening for small arcs ... E 234, L 284
Bi-metallic conductors ... E 70
" electric transmission Co ... N 513
" telephone conductors, A. E. Kennelly ... A 108
" telephone conductors and their relation to resonance on long distance circuits, F. W. Dunbar ... A 81
" telephone wires, Self induction and. A. N. Mansfield ... A 65
" wires for telephone conductors ... A 32
" " in telephony ... E 31
Bismarck, Electric light for ... N 325
Bliss automatic muck bar shear ... *T N 443
Block signal, Sheehy electric. ... *A 139
" signals ... E 71
Boiler, How to operate a ... A 257
Boilers in the Milwaukee station ... L 328
Bonetti-Wimshurst machine ... *A 409
Bonneau & Desroziers high speed electric locomotive ... *A 482
Boston overhead wires ordered down ... N 533
" & Maine station, Electric lighting, heating and power plant, A. C. Shaw ... *A 485
Brady, Paul T ... N 329
Brake shoe, Wharton wooden ... *A 498
Brake and fender, automatic ... *A 127
Brakes, the question of car ... E 13
Bremen electric railroad ... *A 322
Brenner's one voltmeter method of switching dynamos in parallel ... *A 150
Bridge at Omaha, Storage battery on ... *A 149
Bristol Co ... T N 104
Bristol's recording wattmeter ... *T N 508
Brooklyn, Big trolley travel in ... N 549
" bridge, estimated cost of substituting electricity for cable ... A 532
" bridge, To electrify ... N 252
" Edison Illuminating Co ... T N 378
" Electrical Society ... N 501

THE ELECTRO-MAGNET; or JOSEPH HENRY'S PLACE IN THE HISTORY OF THE ELECTRO-MAGNETIC TELEGRAPH.—I.

BY

Mary A. Henry

WHILE reading Miss Henry's remarkable presentation of her father's great work in connection with the Electric Telegraph—remarkable in the power she has shown in grasping the essential features of her father's labors—I was reminded of my first interview with Joseph Henry. One morning he came into my laboratory at Cambridge, and, after I had shown him various pieces of scientific apparatus, he stood before an electro-magnet which was working a relay and looked long at the magnet, and then at the battery which was coupled for quantity, and remarked in a quiet tone, as if half to himself, "If I had patented that arrangement of magnet and battery I should have reaped great pecuniary reward for my discovery of the practical method of telegraphy."

Miss Henry can speak with authority upon her father's aims and labors, and the conclusions she draws from his conversations and from his notes and letters are in consonance with the belief which has been steadily growing, that Joseph Henry invented the essential features of telegraphy.

JOHN TROWBRIDGE.

THE ELECTRO-MAGNET.

Joseph Henry.

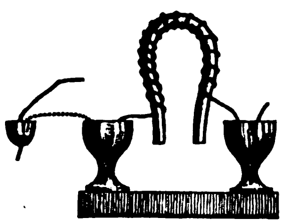
IN the civilized world is there anything which in this day contributes more to the comfort of man than the electro-magnet? Strike it out of existence and the electric telegraph would die. Its great network of wires would be as useless as the curious system of nerves which carries the message of the brain to the finger tips is useless when that mysterious principle which constitutes the life of the human being has departed. The telegraph gone, distant countries would unclasp hands, as it were, and the wide ocean roll again between. The eager world would be struck dumb in the midst of its innumerable political, commercial and social relations; or, rather, would be sent back to the stammering old time when months intervened in the exchange of thought, now possible in an hour. But not alone as the soul of the telegraph would the loss of the electro-magnet be felt; hardly a moment's thought is needed to realize the place it has gained, the importance its failure to meet the demands made upon it would be to the world. How did it come into existence—this electro-magnet? Perhaps, considering the importance of the subject, it may bear to be not merely a twice-told, but an oft-repeated tale.

What is a magnet? Our acquaintance with it began in our childhood : as a piece of steel endowed with a mysterious attractive power, it was among our toys; many a time have we held it over a pile of needles and laughed to see them leap to meet it, or with it we have drawn our little boats from the farther side of a mimic sea. How did it receive its name? It is pleasant in imagination to travel far away through the beautiful islands of the Ægean sea to the shores of Asia, and to believe in the romantic story which tells us that a Greek shepherd, Magnus by name, wandering over Mt. Ida with his sheep, found his crook suddenly and powerfully attracted by a mass of iron ore, and so attached his humble name to the loadstone or natural magnet. But fancy must yield with reluctance to the more prosaic assumption now generally adopted, that the name was derived from Magnesia, in Lydia, where the ore was first found.

For the word *electro* we must not only come down the mountain, but descend the stream of time to about five hundred years before Christ; then we must follow the undulations of the Ionian coast, to find, at the mouth of the river Meander, the city of Miletus. Walking her streets at this time, caring little for her magnificence or for the wars in which she was engaged, save to induce peace, was Thales, one of the seven wise men of Greece. Among the objects of trade in the magnificent city was the yellow amber; not an object of indifference to the philosopher, although as yet only of frivolous use as an ornament. Its color no doubt delighted his eyes but it had a deeper interest for him. Rubbing the stone one day—perhaps to make its yellow tint clearer—he found that he had endowed it with a curious power: a loose feather flew to meet it. This power seemed to Thales miraculous. He imagined there were spirits in the amber and so came to think that everything in the universe must be pervaded by spirits. Thus electricity was discovered, and it received its name, long afterwards, from the Greek word meaning amber.

It was at a very early period that the loadstone or natural magnet was discovered. Very early too was known the remarkable power it possesses of transmitting its properties to hard iron or steel when these bodies are rubbed, or even touched by it. Thus came into being the steel magnet—possessing not only the same power of transmitting its properties but also a quality lacking in the ore; turning north and south, when free to move, in obedience to the great magnet, the earth, it had a directive power which more than two thousand years before the Christian era directed the traveler over the land, as later it was to guide the mariner over the sea. From this remote period it is a long flight down the ages until in England, in the cabinet of the self-taught shoemaker-philosopher, Sturgeon, stood the first electro-magnet; that is, the magnet made by electricity.

Of the deepest interest to the scientific world was this little instrument. It consisted of a small bar of soft iron bent into the form of a horse shoe, with a spiral of wire wound loosely around it, the ends of the wire dipping into two cups of mercury. When into these cups the wires from a galvanic battery were also dipped, an electric circuit was formed and the electric current, passing through the spiral of wire, rendered the soft iron bar magnetic. It was very feeble, this magnet; it required a large battery to give it any strength. What advantage could it boast over the steel magnets which had served the world so many years?



Sturgeon's Magnet.

Some of these were very powerful; one in London at this time belonging to the Royal Society lifted one hundred pounds. These magnets were all permanent: steel when endowed with magnetism retains it; not so soft iron. This bent bar of Sturgeon's was a magnet only while the electricity was circulating through the wire around it; in this lay its advantage: *it was a magnet, or not, at the will of man.* It was not merely as a scientific fact that the world turned to it with such eagerness; it renewed an old hope that electricity might be made the messenger of man. The story of the electro-magnet is but a part of the story of the electric telegraph; we may not tell the one without reference to the other.

We cannot go back far enough in the history of man to find a time when the idea of the distant communication of intelligence did not exist. In the earliest childhood of the race even, beacon fires proclaimed from hill to hill tidings of weal or woe. In those early days man looked up with dread to the lightning, thinking it "the eye-flash of an angry god," not dreaming that it was the manifestation of the agent which was to satisfy his long-cherished desire for distant communication with his fellowman, that the very genius of the storm was one day to serve as his messenger.

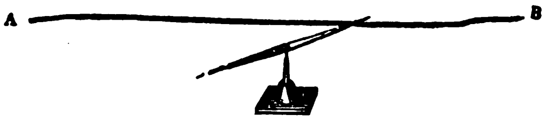
It is interesting to know that Hauksbee of England in 1705 was the first to suspect the identity of lightning and electricity. He produced a thunder-storm in miniature by drawing a piece of amber swiftly through a woolen cloth. He says "a prodigious number of little cracklings were heard, every one of which produced a little flash of light. This light and crackling seem in some degree to represent thunder and lightning." As man learned in various ways, by the rubbing of amber and other substances, to excite electricity, and learned also the value of the force thus produced, also that the electrical influence could be transmitted through several hundred feet of wire, there came to him the conception that by the friction of his machines he might, as Aladdin by the rubbing of his lamp, summon the slave of his will which was to serve in the transmission of intelligence. The first attempts to use electricity for this purpose began in 1753. Who was the first to suggest the idea it seems difficult to determine; it was such a natural idea after the experimental results which had been obtained that it probably occurred to many minds at the same time, and it is only surprising that it was not conceived earlier. We may not here notice any one of the efforts in this line founded thus on frictional or static electricity; they form one of three distinct, although overlapping, eras in the history of the telegraph. They had a measure of success. They were very interesting from a scientific point of view and they served certain ends, but they did not give the telegraph to the world.

[By the telegraph I mean here that system or combination by which mechanical effects can be produced at *great distances*—through seas, over continents—and I use the term in contradistinction to the many attempts towards this result, made at various times and in various places which if successful were so only in a limited degree, because the natural laws which control electrical action were undiscovered or unknown. Will the reader be so kind as to take especial notice of this remark; it is necessary for the proper understanding of my story.]

In Bologna, in the year 1753, a "religious youth of fourteen years was dreaming of church service, discouraged by his friends; while on the shores of Lake Como was playing a boy of eight;" these two were destined to make the discovery which was to form the second era in the history of the telegraph. In 1789, a dead frog's leg hanging upon a copper hook and kicking as though it were alive whenever the sportive wind blew it against an iron balcony—electricity at work, in what seemed almost the enjoyment of a jest—revealed to Galvani that by chemical action, as well as by friction, the genius of the thunder-storm might be evoked. Volta followed with his "couronne de tasses" and thus came into being the Galvanic or Voltaic battery, bearing the names of both men. So general and profound was the interest excited that Napoleon Bonaparte invited Volta to Paris, witnessed his experiments with the instrument in the presence of the National Institute, and loaded him with decorations.

More eager now grew the hope of means of distant communication. The electricity of the machine, that is, the electricity produced by friction, had answered for this purpose only in a very limited degree; but this battery,—might not its long wires be extended indefinitely? Might not this current of Volta's, easily excited, easily set at rest, by the mere making or breaking of the contact of those same long wires, at last be the messenger so long desired? Of the many efforts in this direction, led in by Sœmmering of Munich, we may not speak. Could we follow their fortunes, now in one country, now in another, we would find that, however ingenious, sooner or later they all ended in the same difficulty, viz.: *the failure of the electric force with increase in the extent of the conducting wire of the battery.* It was but a question of time, or rather of distance; each new effort met the fate of its predecessors. For a while the electric force seemed to lend itself to this service, only to escape and laugh, as it were, at the efforts of the impotent creature, man, to bring it under restraint.

We turn now again to the electro-magnet. In a former article we tried to tell, in these pages, how the world found out that electricity could produce magnetism; step by step, from Oersted swaying his needle through the influence of the electric current, down to Ampere magnetizing needles in a glass case by means of electricity; we come back to 1824–25, to the bent iron bar in Sturgeon's cabinet and to the interest it excited. Then indeed the telegraph seemed a thing of the near future. There was not only the wonderful Voltaic battery, there was this magnet ready to respond to the will of man; could it not be made thus to respond at a distance? Surely the desire of the world would now be accomplished!



OERSTED'S NEEDLE.

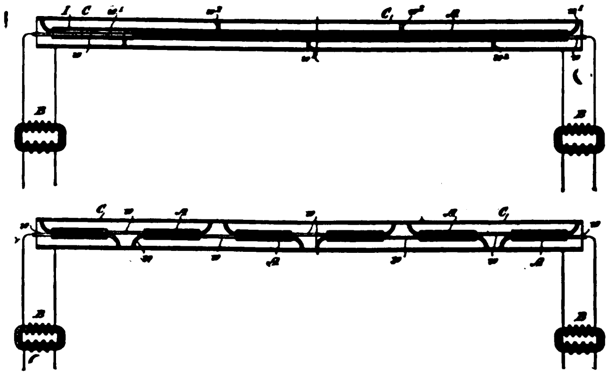
Barlow, a distinguished mathematician and engineer of England, essayed the practical experiment with the new instrument, while Europe waited, we might say, with bated breath, in confident expectation for the result. What was it? Again a disappointment. We will let Barlow speak for himself. "The details of the contrivance are so obvious, the principles so well understood, that there is only this one question which could render the result doubtful. *Is there any diminution of effect by lengthening the conducting wire?* I was therefore induced to make the trial, but *found such a sensible diminution with only two hundred feet of wire as at once to convince me of the impracticability of the scheme.*" It could not be possible! The experiment was repeated in various ways, in the same year, 1825, and in the following year, but with like result; each experiment confirmed the reluctant conclusion that after all the brilliant discoveries which had excited such eager expectation, an electro-magnetic telegraph was an impossibility. Since Sturgeon's magnet, as well as Volta's battery, had failed, there appeared to be no means of obtaining sufficient electrical force to act at a distance.

Had the hope of the telegraph indeed ended, and in disappointment? *For want of sufficient electric force the* *telegraph is an impossibility;* such seemed the verdict of the science of Europe, and with it we turn to America. Very brilliant was the old world of science, at that day represented in the line of physics by such men as Hansteen, studying the magnetism of the earth, Gay Lussac and Biot invading even the blue air in the search after the magnetic forces, the immortal Arago, the brilliant Ampere,—we can only mention a few of the names which, enrolled upon the lists of fame, have come down to us as household words. In America, to oppose that eminent array of veterans in this particular field of science there was only young Henry, in the Albany Academy.[1] He dared to brave the electric force and demand of it greater energy. Mr. E. N. Dickerson says of him—"He was but a youth and ruddy and fair of countenance, armed only with a simple sling of his own construction and pebbles from the brook of nature, but he was equal to the trained warriors of maturer growth and superior armor, waging war against the Goliath that guarded the unexplored regions of nature's secrets; and like the great king of Israel, after the hunt of the battle was over, he came to be leader of the hosts who once had been tending only a few sheep in the wilderness."

THE REED INDUCTION SYSTEM OF TELEGRAPHY.

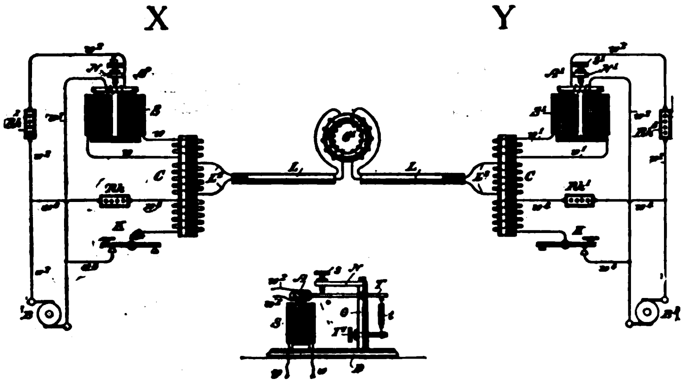
In the operation of telegraph lines the amount of energy required for the transmission of signals is of little account as compared with the importance of securing high speed. Thus, were it possible to increase the commercial capacity of an Atlantic cable ten times by the continuous use of one thousand horse power in current, instead of that of a few cells of battery, it would be an economical step on the company's part to substitute the power plant. The static capacity of long cable, under existing conditions, however, prevents the possibility of transmitting any large quantity of energy or of making variations travel with the desired speed.

Some of the most distinguished electricians of the day have endeavored to overcome this difficulty. About twenty years ago Mr. Edison proposed to do away with static capacity almost entirely by breaking up a long line into shorter circuits and employing induction coils; but his system was confined to a dot and space code, and the action of the armature was unreliable. Prof. S. P. Thompson's method of transmitting a current the whole length of the line and then overcoming static retardation distributively, is still fresh in the minds of those who listened to his paper at the recent Electrical Congress or read the published reports of the proceedings;[2] but while furnishing valuable food for thought, and much that was theoretically novel and valuable it seems to be open to several practical and mechanical objections. Other inventors have devised ingenious systems to overcome the difficulty but none has yet proved useful in practice.



FIGS. 1 AND 2.

Mr. C. J. Reed, of Philadelphia, has recently worked out a method embodying principles which seem to meet the requirements of the case and in a manner distinctly novel and to all appearances practically available. In his system he employs a true alternating current successively induced in separate metallic circuits which may be entirely insulated from one another. This enables him to use high electromotive force and transmit large quantities of energy and reduce the static retardation practically to zero. At the same time almost any receiving instrument may be used, as it is only necessary to provide it with a local means of maintaining the temporary effects of an inductive impulse until the reverse inductive impulse arrives to destroy it.



FIGS. 3 AND 4.

In the accompanying illustrations, Figs. 1 and 2 show the form of cable employed. In Fig. 1, *w* and *w'* are insulated conductors lying side by side throughout the entire distance between two stations, the conductor *w* being connected at each end of the line directly to the terminals of the converters B and to the outer metallic coating C, while the conductor *w'* is connected at both ends directly to the metallic casing. w^2 w^2 are insulated branch conductors located at stated distances apart, those on the lower side of the drawings connecting the conductor *w* directly with the outer metallic casing C while those on the upper side and intermediate between those described connect the conductor *w'* with the metallic casing. I is a metallic sheathing of iron wound in layers around two parallel conductors *w* and *w'*, constituting an inductive field around them.

When an impulse is set up through the primary of, say, the left hand converter B, a secondary or induced impulse will be set up through the conductor *w* and the first one of the short conductors w^2 returning through the outer casing C, thus inducing in the first section of the conductor *w'* an impulse which in turn induces in the next succeeding section a corresponding induced impulse; and so on through the series until the final impulse is effected through the conductor *w* and its connections through the coil of the right hand converter B which in turn induces the working impulse in the receiving instrument.

In another form shown in Fig. 2 the continuous conductors are replaced by a series of short conductors *w w*, the ends of which project past each other in alternating order and are connected to the outer casing C, the parallel or inductive portions of the circuits being surrounded with iron wire, as shown at A, while the intermediate portions between these casings form the conducting parts.

In Fig. 3 are shown two main telegraph stations X and Y joined together by an intervening cable consisting of an internal conductor L^2 insulated from a surrounding conducting shield L, the two portions constituting the direct and return conductors and including in their circuits at the opposite stations the secondary coils of two converters C C, and the similar coils of an intermediate converter C′. B and B′ represent two direct current dynamos, and K and K′ the transmitting or signaling keys at the transmitting stations, connected in local circuits with the generators through the primaries of the converters C and C′, rheostats Rh and Rh' and conductors w^3 and w^4.

---

[1] NOTE.—"On the shoulders of young Henry has fallen the mantle of Franklin" were the words of Sir David Brewster. It is true Cox had suggested a chemical telegraph and Hare made many improvements in galvanic apparatus, but no representative of Franklin, in a series of connected experiments, had entered the field of electric science in America, until Henry began his researches.

[2] See THE ELECTRICAL ENGINEER, Aug. 30, 1893.

S and S′ are the receiving instruments connected through conductors w and w' with additional coils on the converters C C. The armature levers A and A′ may be permanently magnetized, or they may be energized by coils included in permanently closed local circuits w^2 w^3, including rheostats Rh^2, Rh^3, so that the influence of the retractile springs t will prevent the armature from being drawn forward under normal conditions (Fig. 4).

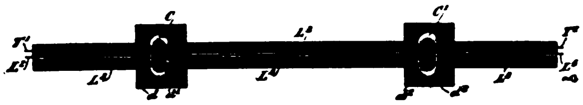


FIG. 5.

When the operator at station X closes the key K an inductive impulse will be set up in the local circuit w^3 of the converter C, which sets up two individual secondary impulses, one in the main line L L² running to the distant station Y and the other in the receiving instrument S, the magnetic effect of which is such as to momentarily increase the pull on the armature A sufficiently to enable the armature lever T to overcome the influence of the spring t and draw it into the forward position shown. In like manner the impulse sent to the distant station sets up in the secondary of the converter C′ an impulse which, acting through the coils C, secondary circuit w' and coils of S′ causes the armature A′ to be drawn into its lower position as shown. Both armatures will therefore remain in their lower position by virtue of their own magnetism after these impulses cause them to be brought down until the key K is opened, when like impulses in a reverse direction cause both armatures to be repelled. Hence for simple inductive impulses, signals may be transmitted, such as the Morse code, in which the elements of the characters are of varying lengths.

In Fig. 5 is illustrated an apparatus for use in cable telegraphy or on long land lines, which consists of a series of converters C C′ located in the body of the cable, the outer surface being of metal constituting a common return circuit for the primaries of all the converters. T′ represents a test line embedded in the cable for detecting breaks.

It will be seen also that the inventor is enabled to insulate all receivers from the main line by several inches of air space and interpose a grounded piece of sheet metal of any size required to prevent the possibility of lightning reaching the receiver. It may also be adapted to telegraphy between moving trains with the same facility as between fixed stations.

The system does not involve the use of a new code or the slightest change in the present one and entails very little expense in changing from the present Morse system, as the same instruments are employed with only a modification of the armature. Another valuable feature is the possibility of multiplying the messages sent by creating similar impulses on a number of lines radiating from the same point. Mr. Reed claims that with his system several hundred words a minute might be sent from New York with an automatic transmitter, and simultaneously received in all the great capitals of the world.

A FRANCHISE has been granted to I. Sparks for operating a local telephone exchange in Santa Fe and vicinity. The poles are erected, and the system will soon be in operation.

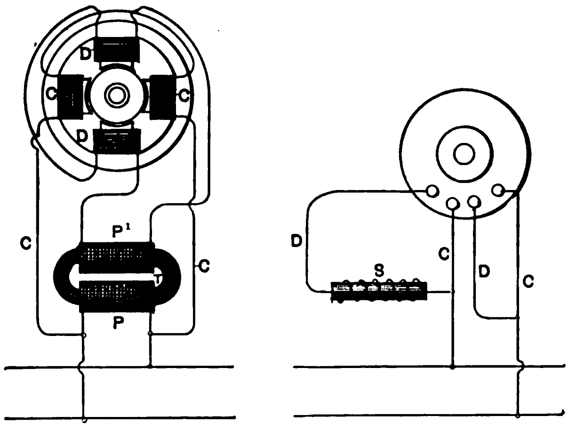
TESLA MOTORS OPERATED FROM SINGLE PHASE TWO-WIRE ALTERNATING CIRCUITS.

THOSE who have followed Mr. Tesla's work in alternating motors will recall that in 1888 he first drew public attention to his new multiphase system of operating alternating current motors, in a paper read before the American Institute of Electrical Engineers, in which he laid down the principles which have since been practically applied in many ways. In this system, it will be remembered, each motor contains two or more independent energizing circuits through which are passed alternating currents, having in each circuit such a difference of phase that by their combined or resultant action they produce a rotary progression of the poles or points of maximum magnetic effect of the motor and thereby maintain the rotation of the armature.

A multiphase system of this kind, however, requires at least three wires for its successful operation, to convey the currents differing in phase, and Mr. Tesla, therefore, early set about to devise means for operating phase motors from the ordinary single-phase alternating circuit, by creating the difference of phase locally at and in the motor. The various ways in which this can be done are described in two patents just granted to Mr. Tesla, which are of special interest at this time.

In all the methods described below, the fundamental idea involved is to pass a single alternating current through both of the energizing circuits of the motor, and to retard the phase of the current in one circuit to a greater or less extent than in the other. The distribution of current between the two motor circuits is effected either by induction or by derivation.

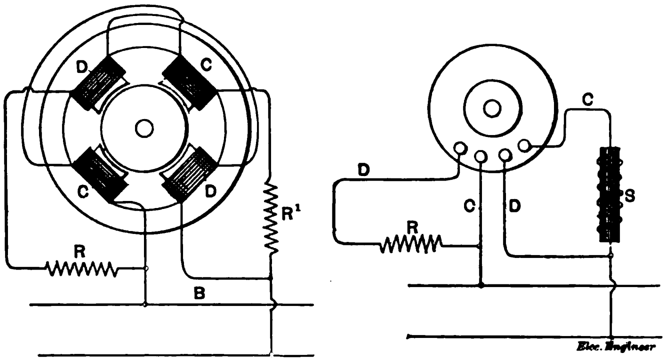
The diagram Fig. 1 shows a motor with two energizing circuits, C and D. One of these circuits, C, is connected directly with the line circuit, while the other set of coils D, is connected up in the secondary circuit of a transformer T. The primary coil P of this transformer, is connected to the line circuit. The alternations of current in the line tend to establish in their passage through the coils C, a polarity opposed to that set up in the coils D, and if the currents in the two sets of coils coincided in their phases, no rotary effect would be produced. But the secondary current developed in the coil P′ of the transformer, will lag behind that in the primary, which lag may be increased to a sufficient extent to practically obtain the same result as though two independent currents were used to energize the motor.



FIGS. 1 AND 2.

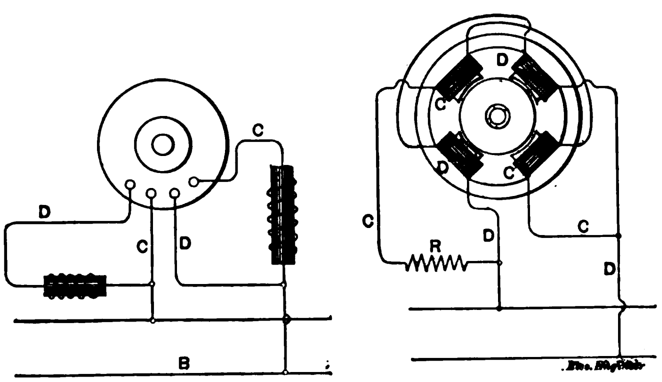
In another form, shown in Fig. 2, the arrangement of the parts is similar to that shown in Fig. 6, except that a self-induction coil S, is introduced into one energizing circuit of the motor. The effect of thus increasing the self-induction in one of the circuits is to retard the phases of the current passing therein to a greater extent than in the other circuit, and in this way to secure the necessary difference in phase between the two energizing currents to produce the rotation of the motor.

In Fig. 3 there is shown diagrammatically a type of motor in which two dead resistances R R′ are included respectively in the energizing coils of the motor. No rotary effect will be produced as long as the resistances are equal, but by varying the resistance in one circuit the retardation of the current in that circuit will be varied and correspond-ing effects produced. For example, a reduction of the resistance in one circuit imparts to the motor rotation in one direction while a reduction of the resistance in the other circuit will produce a rotation in the opposite direction. By means of the two resistances, therefore, capable of variation or of being bodily withdrawn from or inserted in the circuits by simple means, rotation of the motor is secured.



Figs. 3 and 4.

In Fig. 4 a self-induction coil S is included in one of the motor circuits and a dead resistance R in the other. The increased self-induction in one circuit thus produced acts to increase the difference of phase between the current in that motor circuit and the unretarded current in the line circuit. On the other hand, the introduction of the dead resistance in the other motor circuit reduces the retardation and brings the phases of the current in it more closely in accord with those of the unretarded current, thus producing a correspondingly greater difference of phase between the two currents in the energizing circuits C and D.



Figs. 5 and 6.

In Fig. 5, two self-induction coils are shown, one in each motor or energizing circuit. One of these coils is much smaller than the other and has less self-induction or counter-E. M. F. than the other, so that the phases of current will be retarded to a less extent than in the other.

In Fig. 6 the two energizing circuits of the motor are shown connected in multiple arc to the line circuit and in one of these circuits is a resistance R. Assuming the two motor circuits to have the same degree of self-induction no rotary effect will be produced by the passage through them of an alternating current from the line. But if one of the motor circuits, as C, be varied or modified by the introduction of a dead resistance R, the self-induction of that circuit or branch is reduced, and the phases of current therein retarded to a correspondingly less extent. The relative degrees of retardation of the phases of the current in the two motor circuits with respect to those of the unretarded current in the circuit B thus produced, will set up a rotation of the motor.

Finally we may mention another type in which one set of energizing coils is of finer wire than the other or has a greater number of convolutions; or each circuit may contain the same number of convolutions, but composed of different conductors, as, for instance, one of copper, and the other of German silver.

Mr. Tesla has devised still other methods for accomplishing the same purpose, but those described will give a fair idea of the wonderful flexibility of the system.

ELECTRIC HOISTS FOR WHALEBACKS.

A NEW departure is promised in connection with the proposed new ore docks for the whalebacks at Conneaut, O., says the *Evening Wisconsin*. Permanent bridges will span slips 100 ft. wide for the operation of electric hoisting machines. These bridges will be high enough to clear the decks of the whaleback barges by 30 ft. The design is for the steamers, which will tow two consorts each, to put their barges far into these great slips, and then to follow head in, the three passing under the trestle bridges, except that the stern of the steamer, with the stack, will be outside the outer trestle. The cars will then run directly over the hatches, dumping the ore on either side of the slip. The electric hoists require only one man to a car. He travels with the bucket, and dispenses with the signal men and extra engineers and firemen required by the steam hoists. The same power that propels the machinery generates light, so that the stock piles and the holds of the boats can be illuminated and the work carried on by night as well as by day. The method was fully illustrated and described in The Electrical Engineer of Dec. 23, 1891.

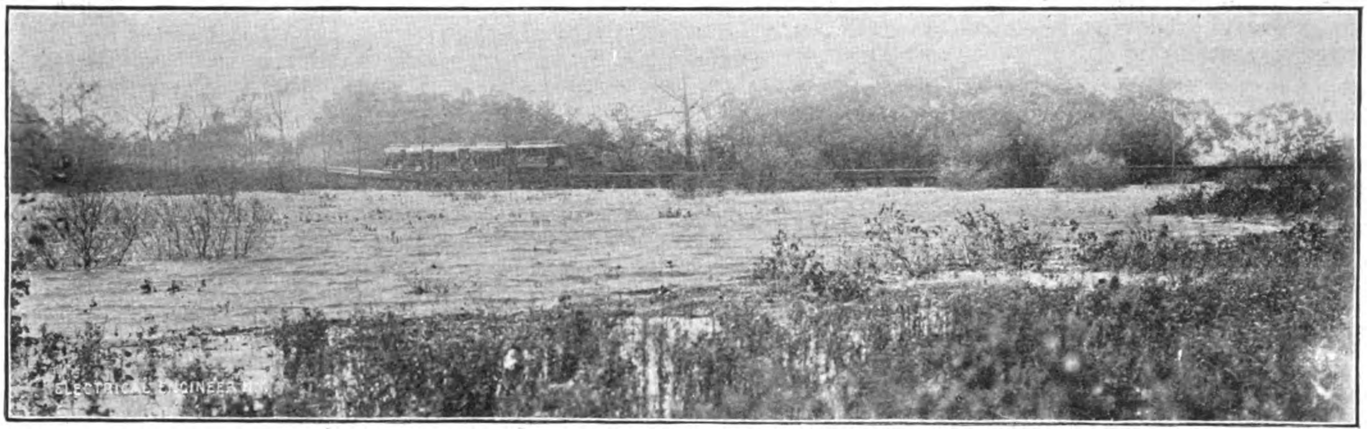
PENNY-IN-THE-SLOT ELECTRIC LIGHTS.

The penny-in-the-slot electric lamps have come into use on the London underground railways this week, says the English *Western Mail*. Trusting to memory, I will say it is two years since the first experimental lamps were put on a few trains. Since then arrangements have been made to fit the lamps to all the trains and the work is now complete. There are four lamps in each compartment. If you want to read, and the ordinary light is insufficient (that is a dead certainty), you put a penny in the slot and obtain an electric light, which lasts you half an hour. If you want more you have to put in another penny. The lamps are conveniently placed at the back of the seat so as to throw the light on the book or paper. They were in immense demand at the outset. Every one wanted a pennyworth of electric light, and I believe people used the trains on purpose to try the lamps. (The apparatus can be seen at the office of The Electrical Engineer.)

ELECTRIC LIGHTS IN HARTFORD, CONN.

Great improvement is expected in the electric street lighting at Hartford, Conn., where President Dunham of the Hartford Electric Light Co. is adopting the Howard incandescent arc system, by which the arc is inclosed in a glass envelope adding enormously to the life of the carbons, giving absolute freedom from flying sparks, and reducing to a minimum the labor of trimming. The Royal Arc Electric Co. of New York, controlling the Howard patents and apparatus, has organized a sub-company in Connecticut, which is to furnish the necessary outfit.

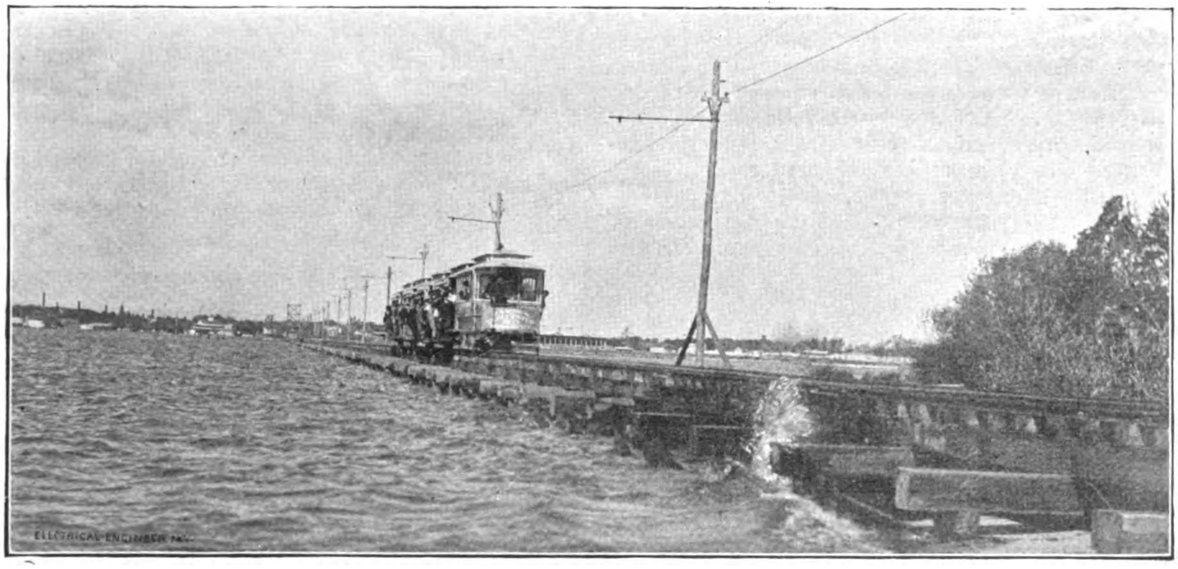
ELECTRIC TRANSPORTATION DEPARTMENT.



ACROSS THE MARSHES: MOTOR CAR, FOUR TRAILERS AND 500 PASSENGERS.

AN AMPHIBIOUS RAILWAY—THE CAMDEN, GLOUCESTER AND WOODBURY.

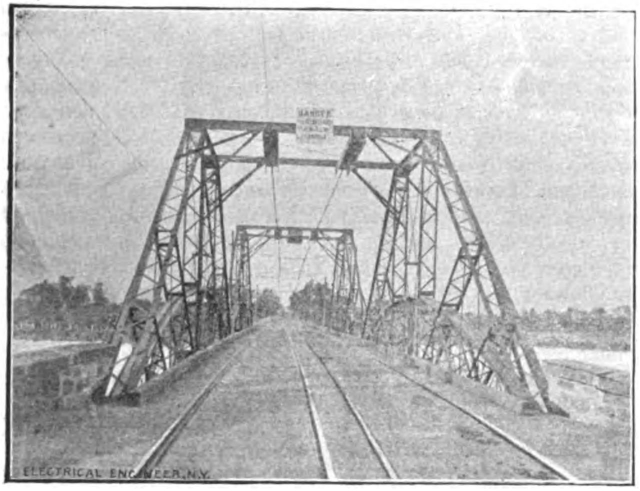
NEW JERSEY along its eastward front is so thorough a blending of sea and land that one is always a little in wonder why the Dutchmen who settled on rock-ribbed Manhattan did not endeavor rather to make their home among the sand dunes and mud banks that stretch south from the Kill von Kull to Cape May. Probably they were rather weary of their job of canal digging and pile driving in old Europe and found more pleasure in a change of occupation. They cannot well be blamed, but New Jersey was too good for other people to neglect, and in these later times, with the aid of the electric railway, the outermost of her shifting sands are being converted into profitable farms and bright summer resorts. Where a dyke would have been thrown up, the modern equivalent is a railway embankment with a trolley line on top of it.



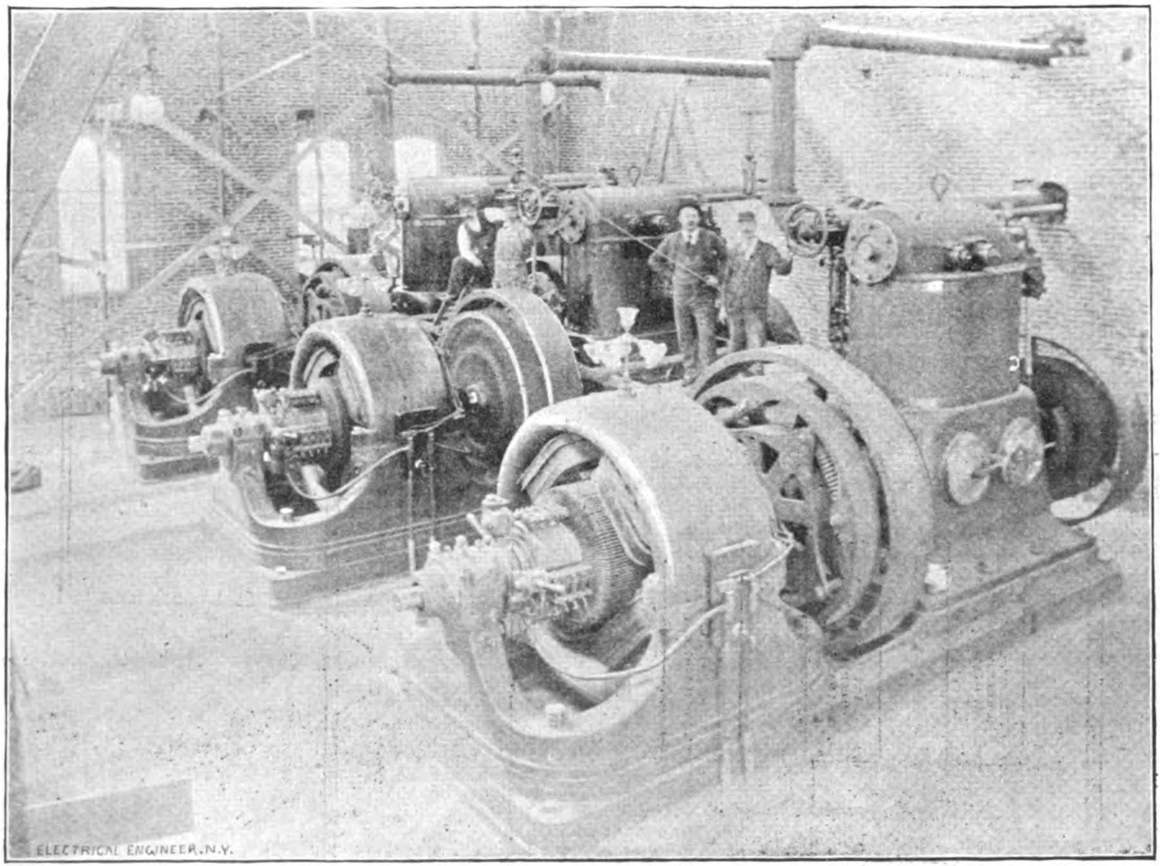
TRAIN OF FIVE CARS CROSSING TIMBER CREEK TO GLOUCESTER.

AT THE DRAW, TIMBER CREEK.

Reference has already been made in THE ELECTRICAL ENGINEER to some of these coast roads in New Jersey, and the coming year will witness several additions to the number. But perhaps the most striking of all is one about which least has yet been said, and as it is very nearly all in operation now, a description will be timely. While it is not exactly a coast road, it is only bald accuracy to speak of it as amphibious, as wallowing in salt water where fresh is not handy. This road is the Camden, Gloucester and Woodbury Railway, built for the company of that name by the Complete Electric Construction Co., of New York city. The three places that give the road its name may be regarded as suburbs of Philadelphia, but have other claims to distinction and liveliness, particularly Gloucester, to whose race track hie the Quaker youth and whose planked shad is a dainty that men have been known to travel three thousand miles in quest of. Rumor has it that at least one American Minister has resigned his embassy in order to enjoy Gloucester planked shad again. If it was not that brought him home, it must have been that other evolution of the spit—"rotation in office." The illustrations that accompany this brief sketch will give an idea in "water color" of what has been attempted and accomplished on the road as it runs across the Jersey bayous connecting one prosperous community with another in a way possible only with the light and flexible trolley system.

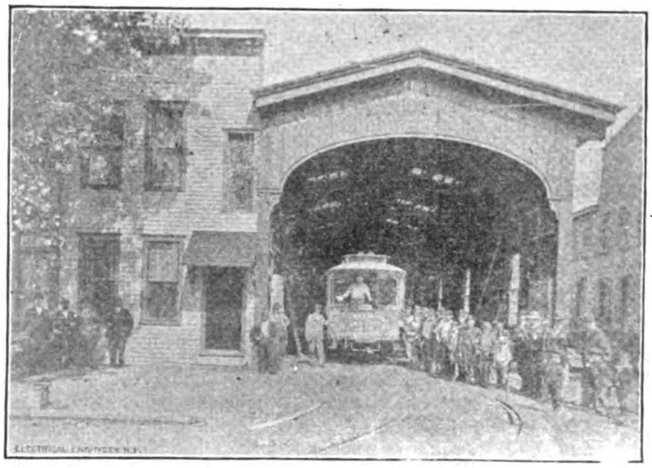


An Old Bridge Cantilevered for the C. G. & W. Road.

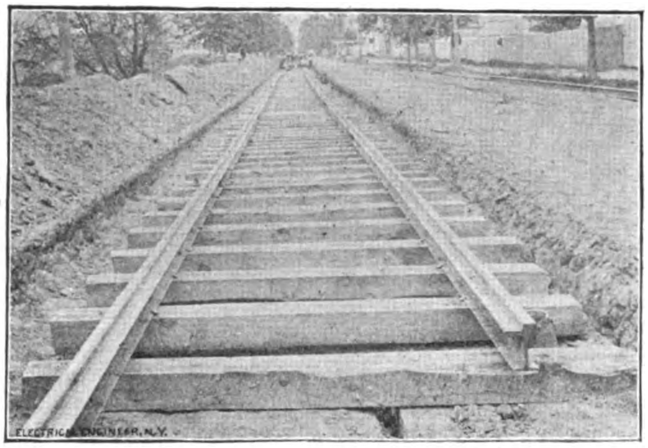


Westinghouse Generating Plant, C. G. & W. Electric Railway.

The Camden, Gloucester & Woodbury Railway Co. have a road which comprises about 5 miles of double track and 5 of single between the places named. The five miles of double track run through the two cities and have 80 pound Johnson girder rail paved up to; while the 5 miles of single are laid with 60 pound T-rail, supplied by the Pennsylvania Steel Co. There are practically no grades worth mention, but on the single track there are six turnouts. Nor are the curves serious; there are eight in all, with a radius of an average of about 50 feet. The line construction is on the cross suspension plan except on the trestles, and the wiring allows for only 2 per cent. loss. The feed wire is No. 0000, the service wire No. 0, hard drawn copper, and the span



Car Barn, C. G. & W. Electric Railway.



Example of Track Construction, C. G. & W. Electric Railway.

wire, ½ inch steel. The rails are bonded with No. 0 iron bonds, and frequently grounded, the water courses being liberally availed of for the purpose, by means of a rail dropped into them. The road is remarkable for the extent of its trestle work, which is, all told, no less than 3,730 feet long. There is one stretch that has as much as 2,480 feet in it, another of 900 and another of 350. The longest piece has in it a drawbridge with 138 feet swing, and the circuit is maintained intact by means of a heavy Roebling submarine cable under the draw. The road also crosses bits of open sandy country and in one place cuts deep through a mile of wood. The illustrations show the strength of the construction, as in two of the pictures—that of the marshes and that of the trestle across Timber Creek to the Gloucester race track,—the train consists of one motor car and four trailers, having on board a densely packed crowd of 500 passengers. It need not be supposed, however, that the allurements of the racecourse alone explain such travel. Camden City has a normal population of 65,000; Gloucester, of 10,000; and the beautiful suburb of Woodbury, about 4,500; and as a matter of fact, the road is the only outlet for travel to the Atlantic section of South Jersey. Hence the necessity for heavy, solid work, and for such reinforcement as is shown in the cut of the bridge that has been cantilevered on top of the old construction, to secure proper stability.

The power plant for this interesting road comprises three boilers of Babcock & Wilcox make, of a total of 1,200 h. p. furnishing steam to three Westinghouse compound engines direct connected, 250 h. p. each, driving Westinghouse generators of equal capacity. The iron stack is 6 feet in diameter and stands 110 feet high. The power house is of brick and iron. A noteworthy feature is that this is in reality a combination plant, as the Gloucester Electric Light Co. has its station in a wing. This lighting plant

Elec. Engineer

Power House of the Camden, Gloucester and Woodbury Railway Co.

includes a Hamilton-Corliss 300 h. p. engine, furnishing power for a capacity of about 200 American arc lights and an Edison machine used in lighting the fine residence of Mr. W. J. Thompson, more popularly known as the "Duke of Gloster." In addition, the Railway Company has a commodious car barn where it houses it rolling stock of 12 motor cars, with Westinghouse two 30 h. p. equipment each, 12 closed trailers and 18 open trailers. These are supplemented by a sprinkler and a snowplow.

As already stated the road has been built by the Complete Electric Construction Co., of New York, of which Mr. John A. Seely is president, and under the supervision of Mr. J. J. De Kinder, as engineer, of Philadelphia. The investment amounts to about half a million dollars.

THE WINKLER TWIN SERIES ELECTRIC MOTOR.

The most serious trouble which has been experienced with double motor equipments lies in the difficulty of dividing the load equally between the two motors under all conditions of service. While this is partly overcome by the use of series parallel controllers, the latter are not wholly satisfactory, for in passing from series to multiple, there are times when the whole of the load has to be borne by one machine, and after the other motor is cut in again it is some moments before the load is even approximately equalized. The United Columbian Electric Company, of New York, have just brought out their improved twin series Winkler motor for street railway purposes, which obviates this difficulty completely. The company own the motor patents of C. F. Winkler, and the improved motor while generally following the design of the earlier type, embodies several important improvements in the details of construction.

In the Winkler motor, shown in Fig. 1, the desired result is obtained by using only one magnetic circuit, or one field for the two armatures, one of the armatures being geared to each axle. By this arrangement the load is equalized between the two armatures, and, as will be seen, the motor has the economical advantages of the single motor, together with the perfect connection of one armature to each axle of the car.

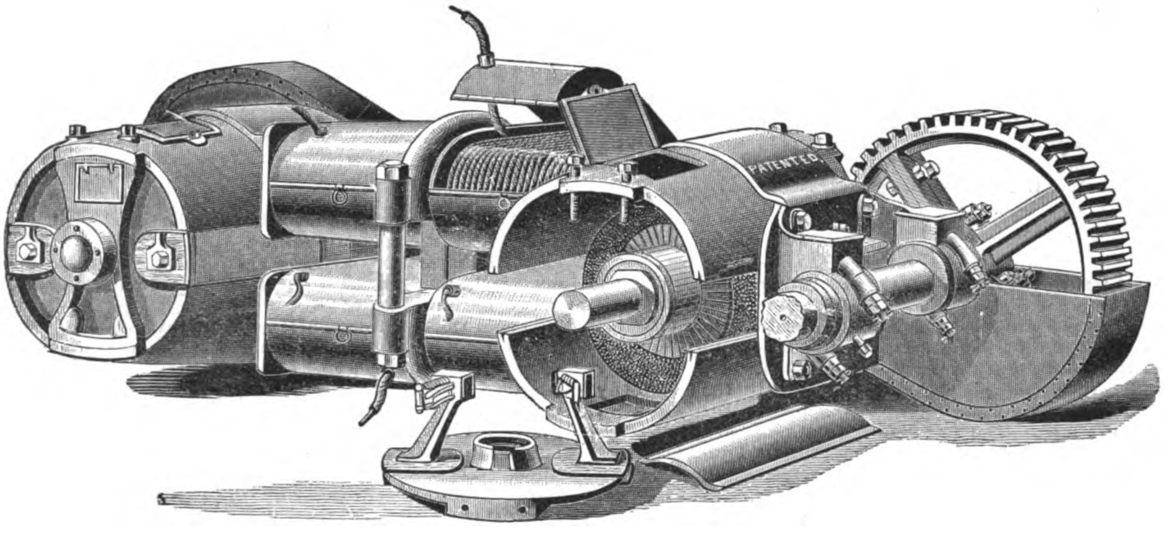

Fig. 1.—New Twin Series Winkler Street Railway Motor.

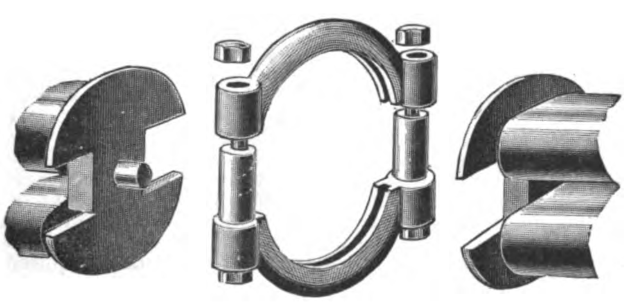

Fig. 2.—Winkler Flexible Motor Joint.

The use of the single magnetic circuit makes practicable the permanent coupling of two armatures in series, for the action of the magnetic lines of force on the two armatures is then identical. This fact compels the two armatures to work in harmony with each other under normal conditions, a result not obtainable when two separate motors with two separate magnetic circuits are operated in series. The efficiency of the equipment is also high, because, as is well known, two motors operated in series with each other are more efficient and can be operated more economically than otherwise, as the counter-electromotive force can be obtained with one-half the number of turns of wire on each armature, which means only about one-half the resistance.

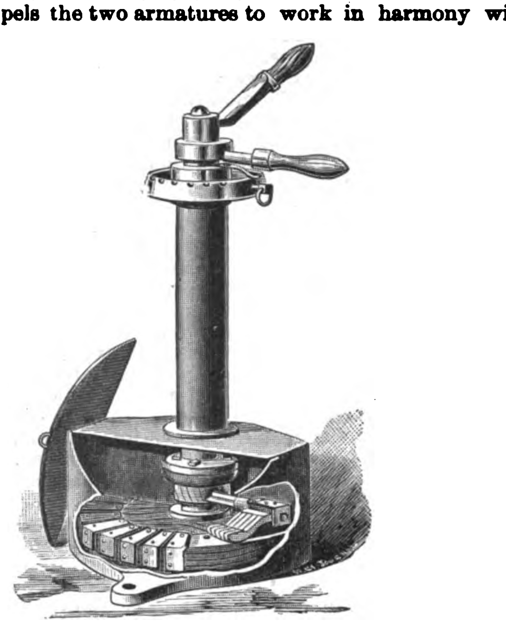

Fig. 3.—The Winkler Car Controller.

In order to avoid the strain on the truck, which would be caused by the rigid coupling of the two axles, an ingenious flexible joint, shown in Fig. 2, has been devised, which, while giving the necessary play between the axles, does not in any way interfere with the magnetic circuit.

The twin motor being a bi-polar machine, can be run with two brushes only to each armature, without increasing the liability for trouble caused by cross connecting the armature coils, as in a multipolar machine.

The controlling device, Fig. 3, is very simple in arrangement and is similar in action to the usual forms of resistance control. An easy start is insured by cutting out consecutively several slow starting coils on the first few points of the switch. After the car is under way the speed can be increased at will by changes in the field circuit. One of the strong points of the controller is that all the mechanism and contacts are on the platform encased in a compact metallic box thoroughly insulated and waterproof.

The controller is made so compact that it does not take up any valuable passenger space, while it insures the perfect protection of all parts from the weather. Another feature is the angle at which the contact fingers are set to the contact plates which prevents arcing between plates when the current is thrown from one point to another. This is effected by engaging each point before leaving the preceding one.

The reversing switch is very simple and is worked by an independent lever. When the motorman removes the switch handle to run the car from the other end, the controller is automatically locked, and cannot be tampered with. The slow starting coils are carefully insulated, fireproof and thoroughly ventilated.

In this motor, while the armatures are usually run in series, either one may be cut out completely, or they may be coupled in multiple when high speeds are desired. In the improved motor the armature is entirely protected from water and dirt, and at the same time the brushes and all parts of the machine are easy of access. All the mechanical features have been worked out with the greatest care. The yokes and supports are made of bronze, and all bearings of phosphor bronze.

The armatures are of the "iron clad" type, the wires being imbedded in the cores in such a way that the winding is carefully protected. Heavy moulded mica insulation is used. The field coils are wound on separate spools, and all parts of the motor are interchangeable and easily accessible. The gears and pinions are cut of cast steel and encased, and all bearings are of ample length. In those for the armature the bearing proper is a loose bushing revolving within the pillow block. It is claimed by practical engineers who have examined them, that by this arrangement the armature bearings will last at least twelve months without more attention than an occasional oiling.

The weight of the motor is all carried on the heavy part at the middle of the axle instead of on the journals, and the rigid connection between the motors prevents all tendency to oscillate. The hammering effect upon the track due to the motion of suspended motors is thus also avoided. The motors are made of both fifty and sixty horse power for a car equipment, and are guaranteed by the manufacturers to work up to their full capacity in continuous service. All the details of the car equipment have been carefully planned, and the very best workmanship and material is used. The factory at Kingston is under the personal supervision of Mr. Winkler, and Mr. H. W. Weller, the new general manager of the company has gained valuable experience during his long connection with electric railway work, with the Sprague, Edison and General Electric Companies.

It is interesting to note that four of these motors are already running so satisfactory at Mobile, Ala., that a fifth has been ordered, and six cars similarly equipped are in operation on the Colonial City Electric Railway at Kingston, N. Y.

AN UNDERGROUND ROAD FOR BOSTON.

By the concurrent action of the Boston Common Council with the action of the Board of Aldermen, the city has finally made a beginning in the solution of its problem of rapid transit. The city has now accepted the act of the last Legislature for a subway under Tremont street, and the Mayor has approved the action of the legislative branch of the city government. The beginning, when finished, will be only a step towards the settlement of the broader question, but it will relieve Tremont street for nearly a mile of its most crowded part, and will also give some improvement to Washington street, the main line of travel and business. Under the act of the Legislature the mayor must appoint a board of three subway commissioners (confirmation to be by the aldermen), who must lay out and construct a subway for street-railway purposes, with two or more parallel tracks, under Tremont street from Pleasant street on the south to Scollay square on the north, with suitable approaches, stations, exits, and entrances. The act forbids the construction of any part of the way under Boston Common. All needed power is given as to means of construction, as regards the right of taking property, and as to the employment of professional assistance. The city is authorized to issue $2,000,000 in fifty-year 4 per cent. bonds. The commissioners shall have the power to compel any line of street railway in the city to make use of the subway on terms prescribed by the railroad commissioners as just and reasonable. The commissioners can also grant to any private corporation the right to put pipes, wires, or conduits through the tunnel upon such compensation as the commissioners shall decide to be proper.

The plan has been to make a light and cheery tunnel, perhaps lined throughout with light brick and lighted with electricity, as agreeable to passengers as the upper air itself.

It is probable that the Subway Commission will not be appointed till the beginning of 1894. Amendments may be asked for the Act at the hands of the Legislature, but the city is now fully committed to the scheme. At best, it will be a purely local relief for a small part of the crowded streets. No other subway is proposed for connection with it, nor will it form a part of any general system. It is merely a dive for a mile underground past a section of Beacon Hill, aiding in no way a comprehensive rapid transit plan.

NEW TROLLEY ROADS.

The Boston News Bureau says: "The American Railroad Improvement Company of Boston, has recently closed a number of large contracts for the construction of trolley roads as follows: A line 14 miles long connecting Sterling, Ill., with the city of Rock Falls, Ill., at a cost of $160,000; a line 28 miles in length running from Red Bank, N. J., to Long Branch, via the Shrewsbury river at a cost of $400,000; a line from Westchester, Pa., to Philadelphia, 38 miles, with stations at intervals of every half mile, standard steam gauge. Cars will be equipped with 250 h. p. motors, and trail cars will be used as far as Philadelphia city limits. This line when completed will be a competitor to the Pennsylvania road, as it is many miles shorter between Westchester and Philadelphia, and considerably better time is expected to be made by the trolley system than by steam. It will cost to construct $1,200,000. A representative of the company is now in Parkersburg, W. Va., closing a contract for the construction of a trolley line at Parkersburg to cost $200,000. This company is also constructing the trolley line between Randolph, Holbrook and Quincy, Mass., which has been completed between Holbrook and South Braintree. Work will be started on all the above lines early in the spring, as soon as the frost leaves the ground. The company has also bid for a number of other roads to be constructed next year, but contracts have not as yet been closed.

MISCELLANEOUS.

THE POOLE & WHITE ELECTRIC TRAIN LIGHTING SYSTEM.

This system, operated in England, embraces a dynamo and accumulators, which for the sake of convenience, are generally placed in the baggage car, although in some cases, such as Pullman and Wagner cars, it has been found more convenient to place a small set of accumulators under each car, so that in the event of such car being detached from the main portion of the train for any length of time, the lamps in that car may be supplied from their own set of cells.

The dynamo being placed in the baggage car, enables the working part of the plant to be easily accessible and examined if required, although it has been found, after working this system on several trains for the past few years, that the automatic arrangements, explained below, are such, that very little attention is ever required.

The dynamo which is sufficiently large to both run the lamps and charge the accumulators, is driven from one axle of the baggage car by means of a belt which passes round an idle pulley and can easily be adjusted to meet the requirements of the belt, should it become too slack.

From the dynamo shaft is driven by means of a small belt, the governor which is fixed either independently or on the frame work above the dynamo. Upon the train reaching a prearranged speed of about 6 miles an hour, a contact upon the governor joins up a circuit of an electromagnet, which in turn connects the main circuit from the dynamo to the accumulators. The accumulators are therefore "charging" until the train speed is reduced to that speed at which it was traveling when the accumulators were put in circuit automatically. At this point, the contact made by the governor altering its position on account of the speed, breaks the circuit round the electromagnet, and allows a spring to switch off the dynamo from the cells.

The electromotive force of the dynamo naturally rises, as the speed of the train increases, and at the same time the position of the dynamo brushes on the commutator is varied by means of the brush cradle being connected with the governor above mentioned, by means of a chain. This prevents sparking and consequently undue heating. The cradle referred to, changes over its position to the opposite side of the commutator upon the train reversing its direction.

To obviate any fluctuation in the lamps, which would naturally occur, when the circuit is broken between the dynamo and accumulators without a proper regulator, on account of the E. M. F. of the dynamo being greater than that of the accumulators, a variable resistance is placed in the lamp circuit from the dynamo and is automatically regulated according to the output of the machine.

It will thus be seen that the working of the whole plant is entirely automatic. The superiority of the incandescent electric lamp over gas or oil lamps is universally acknowledged, especially in traveling, where the best reading light is naturally required by passengers.

The advantages are also easily seen in the saving of labor over gas, the reflectors of which continually require cleaning, and the carriages fitted with the same have to be taken to charging stations causing delay and consequently extra stock, besides the danger which gas presents in case of accidents; and over oil lamps, which require a special staff kept at all the principal stations to change the lamps, clean and trim them. The proportionate weight, for the same amount of light generated, is also in favor of this plant over gas, and therefore makes a material difference in the gross weight of the train.

At the present time twenty-three trains are lighted by this system on the London, Brighton and South Coast Railway. Four of these trains are expresses and nineteen are used for suburban traffic. An order has also been given to increase this number.

It may also be of interest to quote part of a report on the trains equipped on the Poole & White system on one of the English railways:

"The further experience we have had with our electrically lighted trains shows that they are more serviceable to us than gas lighted trains, principally because we save the extra haulage necessary to run the latter to the charging stations. The former are always ready to go anywhere and there is no need to inquire and calculate if the gas reserve is sufficient for the journey, etc.

"It is estimated that the electrically lighted trains render about 15 per cent. more service than gas trains which, taking the cost of building a train of 10 coaches at only £3,000 means a saving of something like £45,000 in the construction of 100 trains.

"The cost of the maintenance and renewals of the electric light in the 30 trains we had running at the end of June last was £1,462 7s. 3d. for the 12 months, say, £48 14s. 10d. per train; but as two or three of the trains were not brought into work until during the second half of the period the average cost per train would come out somewhat higher. The cost appears to depend very much on the number of trains; when we had only a few, the price was about double what it is now. The more trains we have, the lower the average cost for maintenance, the saving being in labor.

"We are now about to fit up 10 more trains, making 40 trains in all, and then we anticipate the cost for maintenance will be less than at present as the incandescent lamp patent expires this year and the accumulator patent runs out next year, I believe."

FIRST COST, PER TRAIN OF TEN COACHES.

1. *Gas.*—In all, including traveling cylinders, buildings, engines, etc., about £650 to £700 per train.

2. *Oil.*—About £120 per train. This does not include cost of buildings, etc., for cleaning and repairing lamps.

3. *Electric Light.*—£400. This price is inclusive of undergear, and, when once equipped, the train is independent and carries its own lighting plant with it and can be sent anywhere at any time.

WEIGHT.

1. *Gas*, 3 tons, 7 cwt. 2. *Oil*, 7 cwt. 3. *Electric Light*, 2 tons, 15 cwt.

MAINTENANCE.

1. *Gas.*—The cost of gas cannot be definitely obtained per train mile, but costs ½d. per hour per compartment = £120 per train of ten coaches per annum. This is for a readable light; but the cost depends almost entirely upon the light supplied, Two burners would give a more satisfactory light but at double the cost.

2. *Oil.*—Varies from £70 to £130 according to the quality of oil and amount of labor used.

3. *Electric Light.*—The actual cost for the last year's maintenance of 30 trains on London, Brighton and South Coast Railway was £48 14s. 10d.

THOUGHTS ON COSMICAL ELECTRICITY.[1]

BY PROF. ELIHU THOMSON.

PROF. THOMSON prefaced his remarks by stating that it was not his intention to give an illustrated popular lecture, but rather to present to the Electrical Section of the Institute a number of thoughts which had come to him, and which must be regarded as in the nature of speculations or guesses. He had attempted to apply known principles to conditions of the heavenly bodies, and he thought there was much to learn in this field.

Beginning with the consideration that as we rise from the earth's surface to different altidudes there appears to be a gradual increase of potential with respect to the ground, such that at a thousand feet, as at the top of the Eiffel tower, there may be 10,000 volts difference between the air at the top and the surface, he assumed that this difference might increase as we reach high altitudes, and that at 20 or 30 miles the potential difference might amount to a million volts more or less. This would seem to indicate the possession of a positive charge by the higher layers of the atmosphere. He stated, however, that it had not yet been proved that a pure gas could carry a charge of electricity, and instanced the case of a drop of water suspended in the air and charged to a certain potential,; if the air were dry and the drop evaporated, the potential would rise gradually until, when it was entirely evaporated, the potential would be infinite. This consideration would be based on the fact, if it be a fact, that liquids in evaporating do not part with their electricity. The increased potential of the drop, however, might have other effects, such as the repulsion of its particles and its division into an extremely comminuted state. Still, on evaporation to pure vapor the electricity must go somewhere.

After stating the nature of the electrical charge as dependent upon capacity and potential, he showed that whenever the capacity is diminished, the potential with a given amount of electricity rises, and vice versa; but went on to state that attraction and repulsion, and other phenomena could be explained by the general tendency of all bodies to increased capacity. He adduced considerations going to show that there was a relative repulsion between liquid charges of electricity besides the attraction between opposite charges, and that therefore, the lines of electrostatic stress would agree with those of magnetism in their tendency to shorten and also to spread laterally.

He then took up the question as to whether a perfect vacuum is, or is not, a conductor of electricity and brought forward the results of recent investigations as showing that an excellent vacuum is not a conductor, but on the other hand is the most perfect insulator. Taking this in connection with the fact that dense air is a good insulator, that rarefied gas is a fair conductr, and that the solid body of the earth is a conductor, he compared the earth to a huge condenser possessing a positive charge in the outer layers, while the earth itself might be less positive or negative. Using the results of Prof. Rowland's works on the movement of a charged body giving rise to magnetism, and the principle of an air condenser, he put forward the idea that the earth, being a huge rotating condenser with a positive charge in the upper layers of the atmosphere and negative charge at the ground, it would necessarily follow that the magnetism could be developed in the region between this upper layer and the earth by the rotation of these charges.

He then traced the actual direction of the magnetism which would be produced, finding that the direction was the proper one to accord with facts and that the compass needle indicates the direction. He reverted to the idea which had come to him that possibly thunder storms were in a measure due to flaws in the dense air as a dielectric and explained in detail, somewhat, his thoughts on this subject. He drew attention to the consequences which would follow the possession by a mass of nebulous gas of a charge of electricity; this, if insulated in space, would, as its volumes diminished by the radiation of heat and condensation, gradually increase in potential, however small the charge originally possessed. The sun might, therefore, be a charged body having a relatively high potential, which potential would undergo elevation on further condensation. He put forward, as a thought on this subject, a possible explanation of the solar periods as due to electrical states, the sun reaching a certain potential and then by the repulsion of small electrified particles losing that potential by the passing of the coronal stream, and not only a part of the charge which it possessed, but also a considerable amount of the charged material which might be encountered by the earth in its movement around the sun, and so gave rise to an auroral display. He showed that the action would necessarily be the periodic one. He showed the tendency of electrified bodies to lose their charge, especially in the presence of rays of light and the higher rays of the spectrum, and thought that this action might possibly have some relation to the possession of and disposition of charges by the heavenly bodies.

He concluded the lecture by stating that it was possible, in his opinion, that temporary stars, that is, stars becoming visible and then fading away, might therefore be explained on an electrical hypothesis, viz., that charged bodies possessing a difference of electrical potential when they approach near enough might exchange electricity between themselves on the grandest scale, giving rise to a uniformity of charge on their leaving each other; that this would naturally be done in a vast display which would only last for a moment of time. He stated in conclusion that these were only thoughts after all, but such as he believed would be of interest to the members of the Section.

SOCIETY AND CLUB NOTES.

FRANKLYN INSTITUTE MEDALS.

THE FRANKLIN INSTITUTE, of Philadelphia, calls attention to its special rewards for meritorious discoveries and inventions in the shape of the Elliott Cresson gold medal, the John Scott legacy premium and bronze medal, and the Edward Longstreth silver medal of merit. Full information as to the manner in which these medals are awarded can be obtained from Dr. W. H. Wahl, the secretary of the institute.

AT the annual meeting of the Institution of Electrical Engineers, Mr. Alexander Siemens was elected president.

---

[1] Abstract of a lecture delivered before the Electrical Section of the Franklin Institute, Tuesday, December 12, 1893.

THE
ELECTRICAL ENGINEER.
[INCORPORATED]
PUBLISHED EVERY WEDNESDAY AT
203 Broadway, New York.
Telephone: 3860 Cortlandt. Cable Address: LENGINEER.

GEO. M. PHELPS, President. F. R. COLVIN, Treas. and Business Manager.

Edited by
T. COMMERFORD MARTIN AND JOSEPH WETZLER.
Associate Editor: GEORGE B. MULDAUR.

New England Editor and Manager, A. C. SHAW, Room 70—620 Atlantic Avenue, Boston, Mass.
Western Editor and Manager, L. W. COLLINS, 1439 Monadnock Building, Chicago, Ill.
New York Representative, 203 Broadway, } W. F. HANKS.

HIGH INSURANCE RATES.

FROM time to time we have quoted the opinions of insurance experts as to the dangers resulting to property from the use of electricity, but we have seldom struck anything more terse and vigorous than the utterances of Mr. Francis W. Whiting, manager of the New York Tariff Association, while in Boston a few days ago. That gentleman says of electricity:

> "Before its almost universal use, insurance companies made money, leaving out the years of the Chicago and Boston fires. The insurance business prior to the extensive use of electricity had been conducted at a profit. You will notice that the people who burn are not the bad element. They are people who don't want to burn, so that the moral hazard feature is not a very important factor in the fire loss. We are losing by fire the very choicest risks, risks we made money upon at one time. What burns them? Investigate, and you will find in almost every important case it is the concealed wire. One thing to be observed in support of this is that the fires which start from 'unknown' causes are becoming remarkably common, and not in property which underwriters would class as bad risks. The evidence of the distrust placed upon concealed electric wires is demonstrated by the charge made in the universal mercantile schedule against the use of electric lighting."

We need not wonder that after such a deliverance, Mr. Whiting should declare that he knew of no remedy but to abolish the use of electricity. It is a great pity he cannot be accommodated. It would be much easier to abolish Canute Partington Whiting.

But the matter is one to be taken altogether seriously, and since our insurance friends insist that the increase in rates is wholly due to the growing use of electricity, we will state one simple case which shows the absurdity and hollowness of their contention. One of the editors of THE ELECTRICAL ENGINEER lives in a large apartment house uptown in New York. It is wholly residential property, has no stores under it or near it, and faces two sides on open park. It has never had a single electric light in it, and the nearest street electric light circuit is a full block away. Last year, the insurance on furniture, etc., secured by this member of our staff was at the rate of 15 cents per $100, through a broker. This year, the rate demanded and paid is 70 cents per $100, although a slight saving of 15 per cent. discount has been effected by dealing direct with the insuring company. Such a case as this, of which all the documentary evidence is in our possession, shows that while it may have been necessary for the companies to get better rates, *electricity has nothing to do with it.* We suggest to Mr. Whiting that if he values his reputation as a shrewd and conservative man, it is time he drew in with an apology the absurd remarks he made as quoted above, and gave electricians the benefit of his advice and assistance in rendering absolutely safe the best light and power now known to man.

ALTERNATING MOTORS FROM SINGLE PHASE CIRCUITS.

THE adoption of the two-phase, or, more generally, multiphase, system of distribution for power purposes at Niagara, after prolonged and careful investigation, carries with it a strong endorsement of the present superiority of that method, and will still further stimulate activity in this field. But, judging from some of the remarks contained in Prof. Forbes' paper, not a few prominent electrical engineers are busy at work on the production of a single-phase motor designed to operate on the ordinary two-wire circuits, and, indeed, a number of such are already in operation abroad on quite heavy work. For those who are working at this problem, the work of Mr. Tesla in this field, illustrated in the present issue, will prove of interest. This far-seeing inventor early recognized the demand which would arise for a motor adapted to be run on two wires, and hence turned his attention to the methods for creating a local difference of phase by the introduction of inductive, as well as non-inductive, devices. The wonderful flexibility of the alternating current is nowhere better shown than in the variety of methods here employed for accomplishing the same common object.

THE BERLINER PATENT.

The suit of the Government for the annulment of the Berliner telephone patent is again receiving attention in the electrical press and in the daily newspapers. Reports are alleged that the case against the Bell Company has made but little progress, and apprehensions are expressed that this suit may be protracted over a period of many years, like the old suit against the Bell patent. We have good reason to say that both the reports and apprehensions are unfounded. The taking of testimony in the case has gone forward with reasonable diligence and there seems to be no reason to doubt that the case will be ready for argument in May next. We are advised that the defendant, the Bell Telephone Company, is even pressing the other side for dispatch in furthering the completion of the proofs. The Bell Company may well be desirous of bringing the suit to an issue as early as possible. In the suit to annul the Bell patent its interests were all for delay, the patent having been adjudicated and infringers enjoined. In the Berliner case the interests of the Bell Company are obviously for an early decision. The Berliner patent has not only never been adjudicated, but the circumstances of its issue after fourteen years delay in the Patent Office afford an additional presumption against the likelihood of injunctions under it pending the final determination of the Government suit.

TAXATION BY FREE PASSES.

Trolley roads that are feeling the pressure of the times might do worse than imitate the example set by the Consolidated Traction Company of Newark and the South Orange and Newark Railroad Company, which are to withdraw all free passes in Newark on and after January 1, so that only policemen and firemen in uniform will be able to take free rides. It appears that these companies have out at least 1,000 passes. If used but once a day, these passes represent a loss to the companies of $18,250 per annum in fares. The probability is that such use as that would be rather the minimum than the maximum; but even if the companies netted only half the amount it would be a substantial addition to their incomes. They could appropriate it in extra dividends, or if philanthropic, raise salaries and give the public a few extra facilities. As a matter of fact, the free pass granted so indiscriminately as to show a list of 1,000 "deadhead" street car travelers on two trolley roads in a city like Newark, would indicate that a similarly judicious reform could be instituted elsewhere.

THE QUESTION OF CAR BRAKES.

The recent animated discussion in our pages on the desirability of some better method of car control has received a noteworthy contribution in an accident that occurred at Troy, N. Y., on December 28. It appears that a car on the Troy City line got away from the motorman. Brakes were applied, but although the wheels ceased their revolution they skidded and the car went on with increasing momentum. The sand box was freely used and other sand thrown on the track, but to no avail. There was nothing left for the passengers but to jump out. One lady in doing so broke her leg. The motorman stuck bravely to his post on the car, which, after knocking over a fire alarm pole and breaking off at its base a telephone pole, plunged headlong against a building which it shook violently and with a great noise. The car was smashed to pieces, and the motorman was so badly injured that he may not recover. Had not the car butted the building at the foot of the hill, it would have committed suicide in the Hudson just beyond.

It would seem that this was a casualty that might have been avoided. It should have been possible to reverse the motor instantly, and run up hill. This was not done, probably because it could not be done with the brakes jammed. As a rule, the brakes on street cars are none too good; but even when they are at their best, such accidents happen. That better, or additional, means of control are needed is obvious.

Electrical Canal Propulsion.

We have received from the New York Produce Exchange a copy of the report made recently by its Committee on Canals, of which Mr. G. W. Balch is chairman. It is an able document and proves once more how great is the value of the Erie Canal to the State of New York. A ready explanation of the desire to improve the Erie Canal facilities is furnished by the statement that in handling a cargo of 90,000 bushels of wheat, a Lake vessel from Duluth to Buffalo, would earn $2,025, while the canal boats from Buffalo to New York—half the mileage—would receive $4,275. The committee approves the deepening of the canal, and speaks most favorably of efforts to apply electrical propulsion. Steam, it says, has been far more economical than the mule, but "it is doubtful if its use can be economized to an extent sufficient to fully meet the requirements." The committee wisely urges the canal boat owners to lend their support to all methods aiming at improvement, and plainly informs them that their prosperity can only come with improved conditions of propulsion.

The Work of Joseph Henry.

Two years ago we had the pleasure of laying before our readers a very interesting series of articles by Miss Mary Henry on the work of her father, Joseph Henry. Since that time, the name of our great countryman has been adopted for one of the new units, thanks, in some degree, to this filial work. Encouraged by the reception of her first series, Miss Henry begins in our present issue a second series devoted especially to her father's work on the electro-magnet and the electro-magnetic telegraph. Prof. John Trowbridge, of Harvard, has kindly written a brief introduction.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.—III.

BY PROF. GEORGE FORBES.

PARALLEL WORKING.

ENGINEERS in America have had no experience in actual commercial conditions of parallel working with alternators. This is partly because the machines which have been made in that country do not work so well as some others in parallel. In the case of the transmission from Niagara Falls my opinion is that parallel working will give the best results. If this arrangement were not adopted it is obvious that when the dynamos are loaded up as much as possible they could never be all fully loaded. It is also quite obvious that if our conductors are to be carried through subways the space required becomes quite excessive unless we adopt parallel working. The complete success of parallel working between Tivoli and Rome left no doubt as to the feasibility, besides the desirability, of adopting parallel working. The reduction in frequency which we have made assists very considerably in this result, and it says much for the American manufacturer who has received the contract that, although parallel working with multiphase machines has not been adopted in the past, he is ready to guarantee the performance in this respect of the machines which are to be built for us.

The rules which govern the construction of machines which shall work well in parallel are not very clearly understood. The only fact which has been perfectly established in practice is that the lower the frequency, the more efficient and sure is the parallel working. It certainly depends to some extent upon the amount of self-induction and the amount of mechanical momentum in the machines. It is also certain that if the self-induction of the machines is too high they will not work well in parallel. Of all machines which have been constructed, those which work the best in parallel appear to be those of Ganz & Co., Mordey, and Elwell Parker, but there are many others which do extremely well. It is, at present, not possible to state exactly the conditions which are necessary, but I may say that, generally, a machine with a stiff magnetic field works better than one where the iron is far below magnetic saturation. In judging whether a machine of a particular type will or will not work in parallel, I think one must be generally guided largely by one's own personal experience in the matter, combined with a knowledge of the effects of self-induction, mechanical momentum, and magnetic saturation as deduced from theoretical considerations. I do not think that anyone who knows anything of the working of the Tivoli-Rome plant would for a moment hesitate in saying that on a large and important station like that of Niagara Falls parallel working is essential; and this is the opinion of Prof. Mengarini, who has so ably directed the works at Rome.

MOTORS.

Under this section it may be as well to discuss some of the different purposes for which the electric current will be required. With regard to arc and incandescent lighting, if the frequency be high enough, the current can be used directly for this purpose; although most people would prefer that, in the case of arc lighting, the current should be commutated or converted in some manner, so as to give a continuous current. That this is unnecessary, however, is amply proved by the perfect success of the arc lighting by alternating currents in Rome and many other large cities, especially those which have been established by Messrs. Ganz & Co. At the present time, one of the largest applications of electricity in the United States is for street railways, which require a continuous current. Another similar purpose which we shall have to consider is the application to canal boats, since it is intended to work the Erie Canal by electricity. This canal starts from the Niagara River, and reaches the Hudson River at Albany, 350 miles distant. For these purposes some sort of commutator or motor transformer will be desirable. Some of the first work which will be done is the supply of much direct current at 150 volts for the production of aluminum. This also requires the continuous current, and similar means must be used for obtaining it. Among the large class of mills which will be established at Niagara Falls, one of the most important kind is wood-pulp mills, one of which is already working on our land, and will be the first to receive water-power from our canal. This type of mill uses many thousands of horse-power, and is worked continuously day and night. In this feature it resembles, probably, a large number of the mills which will take advantage of the cheap power at Niagara Falls. Such mills are working continuously day and night, and do not require to be ever stopped or reversed. This is an important class of work in our case, because current can be supplied to such mills by means of synchronizing alternators whose efficiency is extremely high, and this may, perhaps, be done in some cases without transformers. We require also to consider the case of small motors for use in shops, and for elevators, cranes, and a large number of other purposes. In this type of motor frequent stoppings and reversals are necessary. Hitherto direct-current motors have generally been employed for this latter purpose, but the rotating-phase induction motors are distinctly suitable, and when these have been fully developed they will probably be largely used for this purpose. The commutated current is a thing which is sure to be in common use before long, and although our arrangements at Niagara Falls are perfectly complete without a machine for this purpose, still its employment has been considered by us, and the probability of its future use has influenced our judgment in some points. There are so many purposes for which the direct current is most convenient, that people would generally accept it for transmission if it were capable of being economically transformed up and down to different pressures. The direct-current dynamo is really an alternating dynamo with a commutator placed upon it. If the commutator, instead of being placed there, be placed in the neighborhood of the motor, we obtain most of the advantages both of the continuous and of the alternating current. This is one of the advantages of having two phases generated by the dynamo, because it is much easier to rectify a two-phase current than a single-phase current, In addition to the motors above specified, there are a large number of single-phase motors which start with a powerful torque which have been invented by different electricians, but which are not yet put upon the market. There are also machines with commutators like a direct-current dynamo with laminated field. These all become very efficient and useful when the frequency of alternations is sufficiently diminished.

LINE CONSTRUCTION.

A great deal of attention has been given to the different methods by which current can be conveyed to the points of consumption, whether on our own property or at Buffalo, or even further. Naturally the pole line was first dealt with, in which the poles might be constructed of either wood or iron. This is the cheapest type of construction, and has some advantages, but we must consider the climatic conditions in the neighborhood of Niagara Falls. We are subject there to severe thunderstorms, and troubles from lightning have already been serious in several parts of the United States in connection with electrical machinery. Snow and frost are very severe, and sleet forming upon the wires and insulators may cause a great amount of trouble. There are also at times very violent gales sweeping from over Lake Erie. All these difficulties can be counteracted to some extent, but it is nearly certain that with overhead construction occasions would arise when the continuity of operations would be interrupted, and this would be a very serious matter. The next system to be considered in order of cost would be underground cables, but I am strongly opposed to the adoption of these for any considerable length. It is true we are able to deal with their capacity so as to reduce its injurious effects, but surely the best plan of all is to abolish the capacity itself as far as possible. The most satisfactory method of proceeding is to build a subway of sufficient size to enable a person to walk along it and to carry bare copper conductors in it, but this a matter of considerable expense. I am glad, however, to be able to inform you that the officers of the company resolved last summer that a subway such as I have described should be constructed from the power-house up to the Pittsburgh Reduction Company's works, where aluminum is to be produced, a distance of 2,500ft. In accordance with their instructions I prepared plans, which give space enough to carry the conductors at 20,000 volts for all the power that will be developed by the present tunnel, parallel working being adopted. The subway is built of concrete having a minimum thickness of 10in. The height inside is 5ft. 6in. Wooden beams are embedded in the concrete on both sides every 30ft. When the concrete is set these beams are removed, and iron castings for supporting the brackets that hold the insulators are put in their place, and these are then grouted in. Iron brackets are bolted to these castings, and the oil insulators placed upon them. We shall probably adopt copper strip conductors. The bottom of the subway is always on an incline, and is of curved shape to drain off any water of condensation, but it is also proposed to force air through the subway so as to keep it dry. The 2,500ft. now being completed is all drained at the power-house end by a boring into a water-bearing stratum. At the bottom of the subway the concrete is formed in two steps, the lower one of which supports sleepers for a very light tramway upon which a truck can run to carry supplies, and also to carry the inspector. At first this can be moved by a hand lever, but arrangements are made for eventually driving it by electricity, the conductor being carried on the floor, between the stringers (placed on the ties or sleepers), which form a platform running along the length of the subway. On the stringers outside the rails is placed a screen separating, mechanically and electrically, the part of the subway where the conductors are from the part where the inspectors walk. This screen is formed in 10ft. lengths of wood supporting expanded metal, covered over with plaster up to a height of within one foot of the top, the upper part being left open in the form of a network, through which the inspector can look at the conductors and their supports. These screens are held by iron supports fixed by expanding bolts into the concrete, and can easily be removed. The top of the arch is 3ft. below the surface of the ground, so that it will not be affected by frost. According to the last report, it appears that on October 21st 1,590ft. of this subway had been completed; the total length being put down at present is 2,500ft. Each of the iron castings has a wire attached to it which passes through the concrete, and is soldered to a copper wire running outside the subway along its whole length, and connected to a plate sunk in the water at any suitable points. At every 400ft. cross streets will be made, and at these points there is a manhole. Also at these points, on each side of the subway, four drain pipes, 3in. in diameter, are let in, closed at their outer ends. When the subway is to be tapped for use on the side streets, or for intermediate points, wires can be laid through these pipes. Between Niagara Falls and Buffalo there is very little rock, but the part where the subway has now passed through has been chiefly in rock. This involved blasting out a channel larger than was required. In this case the part of the trench outside of the subway has been built up of stone. In the construction of this subway American Portland cement has been used, and a very suitable sand from the neighborhood, which contains its own gravel. The whole of this work has been done by Mr. Humbert, and up to the date of my last inspection every part was thoroughly and satisfactorily done. This work is of great importance as conveying to the minds of those who intend to use our power some idea of the desire to ensure continuous working.

With regard to the electric pressure that is to be used for distant transmission, this will undoubtedly advance with experience. Some manufacturers in Europe who tendered for the work proposed to adopt 25,000 volts; but we have considered that at present 20,000 volts is not likely to be exceeded by us, and we may work at a lower pressure at the commencement. When it is remembered that the Deptford machines have one terminal connected with the earth, and are working satisfactorily at 10,000 volts, and when it is noticed that, in consequence, our work would be under exactly the same conditions as regards insulation when working at 20,000 volts, it is easy to see that we are not risking anything experimental in our first work.

With regard to the size of conductors, I worked out the economical size at different current densities for the whole distance. In doing this I took the following data:—I took the cost of copper at 12½ cents per lb., and the annual charge on this cost at 5 per cent. I then computed the power loss in the line, and the amount of power which was left available for delivery. I took the value of this power at the distant end of the line as being $15 per horsepower. This is something more than what it costs us to produce it, but when the power available from our tunnel is nearly all consumed this quantity will have to be increased. It must also be remembered that I have not allowed for the increased size of the conductors required by the retardation of phase, which is an unknown quantity. Still, it will be seen that from these considerations we may be able to work economically at a slightly higher current density than is obtained from this investigation. From this work it appears that the most economical density to work at is 350 amperes per square inch. If this density is used the fall in volts between Niagara Falls and the northern boundary of Buffalo is only 3½ per cent.—a matter which makes regulation extremely easy.

With regard to the efficiency of the system, it is remarkable how high the efficiency of the dynamos comes out when we are dealing with the large units of 5,000 h. p. There can be but little doubt that the efficiency, electrical and mechanical, of our dynamos may reach at least 98 per cent. Taking off 3½ per cent. for losses on the line, we would have 94½ per cent. delivered electrically at Buffalo if no transformers were required to raise the electric pressure to the full 20,000 volts. In cases at Buffalo, where the power consumed is very large, the motor can be constructed on the same principles as the dynamo; and if in this case it be ever possible to work at the full pressure without a transformer, it is obvious that the total efficiency of the system—that is, the power delivered by the motor to the shaft of the machinery, divided by the power delivered by the shaft of the turbines to the dynamo—will be certainly over 90 per cent. As a matter of fact, if we were to use a higher density of current, and were to use step-up transformers at Niagara Falls and step-down transformers at the northern boundary of Buffalo, and other step-down transformers in the town of Buffalo itself, and were to use motors of small power, and consequently of less efficiency, in this case the total efficiency of the plant might be reduced to 80 per cent., or even lower.

I have given these figures not as indicating precisely the lines on which we have determined to work at Buffalo, but because the present paper is intended to embrace the subject of the general distribution of power, and I thought it desirable to lay before you certain facts in this connection in a definite form.

DESCRIPTION OF MACHINERY TO BE USED.

Under this heading I shall deal chiefly with the type of dynamo which has been finally decided upon. It will suffice to say of the turbines that they are each of 5,000 h. p., that they revolve at 250 revolutions per minute, and were designed by Messrs. Faesch and Piccard, of Geneva. All the principal parts of this machinery were constructed by the I. P. Morris Company, of Philadelphia, but the governors of the turbines are of Swiss manufacture, and part of the steel fittings were constructed in France.

With regard to the dynamo, the Cataract Construction Company at first invited many different manufacturers in Europe and America to submit plans. The number of these that were submitted altogether amounts to 24, some of the manufacturers having taken a great deal of trouble to submit a series of designs, in order to be able to meet different requirements. Many of these designs were extremely good; but it was determined, after estimating the increased cost of using the European designs, owing to the high tariff in America, and owing to transport, to have the machines manufactured in America. Among the designs from American manufacturers there were none which fulfilled all the requirements of the case, and eventually the Cataract Construction Company decided to get out their own designs, and to submit them to the American manufacturers for tender. I had been for some time previously engaged in working out a design which I am confident none of the manufacturers who had sent in designs could say was in any way borrowed from their ideas. We had received suggestions of an external armature with internal revolving fields, and also of external fixed fields and internal revolving armature. We naturally had a preference for a dynamo with a fixed armature, because the coils can be more securely wound, and are not subjected to the mechanical stresses induced by centrifugal force. But all the designs with revolving fields which had been submitted to us contained a weak feature: the field coils were held in by pole faces secured by bolts or keys to the poles, and this seemed an element of weakness when we considered the enormous centrifugal forces to which the machinery would be subjected. At the same time the turbine makers had insisted upon having a certain momentum, or fly-wheel effect, which was not given by the revolving parts of any of the dynamos submitted to us, and it was found that if anyone of these had been accepted it would have been necessary to add to the design a fly-wheel of large dimensions. Centrifugal force was one of the most important matters to be considered, because at 250 revolutions per minute this force assumes considerable magnitude in the large masses with which we had to deal. Moreover, in all the designs which had been submitted, the magnetic pull between the poles and the iron of the armature assisted the centrifugal force. The principal feature of the design upon which I was working, consisted in having the armature fixed, and inside the machines, with the fields revolving outside; the fields being formed of a ring of iron with the poles projecting radially inwards. One advantage is that we are able to get the full fly-wheel effect that was required by the turbine makers. This requirement was that in the revolving part the sum of the weight in pounds of each part, multiplied by the square of its velocity in feet per second, should equal 1,100,000,000. The design also gives an extremely good mechanical construction for the revolving parts. The iron ring which forms the yoke of the field serves as a support to hold in the pole-pieces and the exciting coils, and no part is held in against centrifugal force by bolts or keys. Moreover, the magnetic pull between the fields and the armature acts in opposition to, and does not assist, the centrifugal force. The armature is fixed, and a large space is available inside it for the workmen to attend to the bearings, and to reach any part of the armature. It is obviously possible to insulate the armature coils for any electric pressure. With a large machine of this kind, the space occupied by insulation has not the same importance in reducing the output of the machine as is the case with machines constructed in the past. In fact, the armature coils can be wound with the same insulating properties as a transformer, and hence the necessity for using a step-up transformer can be avoided.

Starting with this general principle, I first got out designs of a machine at 33 periods per second, in order that I might compare the general appearance of such a machine with those of other types. The next point was to design a machine of as low a frequency as was possible under the limiting conditions as to weight. The revolving parts of the turbine and dynamo, and the shaft connecting them, are supported by a hydraulic piston, and it was the desire of the Cataract Construction Company not to use a thrust bearing of any kind to support the weight, although there is a thrust bearing at the top of the shaft, which simply acts to retain the apparatus in a fixed position in a vertical direction. Owing to this decision, it was necessary to limit the weight of the revolving parts of the dynamo to 80,000 lbs. In getting out the design for the machine it was desirable to select such a form of winding as past experience led one to believe would be most efficient for parallel working, and I judge from past experience that this is best attained by having the number of coils per pole very small. The 33-period machine has only been sketched out with a view of getting at the general dimensions of the machine. It is not suitable for our special purpose, because it is essential that, without taking the dynamo altogether to pieces, we should be able to lift up through the centre of the dynamo any parts of the turbine shaft which may require repair.

It will be seen that from the necessities of the case at Niagara Falls, the dynamo which was required differed in some respects from what would be necessary in may other cases, but it is equally obvious that in any case of so large a transmission of power the conditions must be thoroughly considered beforehand, and the dynamo specially designed for the purpose. At the meeting of the Board of Directors of the Company, in May, 1893, I was instructed, with Dr. Sellers, to get out plans for an alternator of the type which I have described.

I am not able to lay before you now plans of the machine as it has been finally adjusted by conference between ourselves and the manufacturers. In the plan which we prepared, the frequency was 16⅔ periods per second, there being eight poles. The armature coils are so wound that they might be connected to give either 2,500, 5,000, 10,000 or 20,000 volts, and the coils were limited in numbers so as to give the best assurance of good parallel working. For various reasons we decided eventually to raise the frequency to 25, and to lower the volts to 2,000, without the means of connecting the coils to give a higher pressure; and instead of winding the armature on the conductors in a limited number of coils, to adopt the methods more commonly used in some of the large types of generators. But since in any future work which is done, the dynamo will be required to be modified for the special purpose, a description of the machine is sufficiently representative of the type of machine for our purpose.

LETTERS TO THE EDITOR.

THE SIEMENS & HALSKE CO. NOT ENJOINED.

In the ENGINEER or Dec. 20 there appears a note to the effect that "the General Electric Co. have secured an injunction against E. G. Bernard, together with the Siemens & Halske Co. and Major Isaac Arnold, commandant at the Watervliet Arsenal, restraining the contractors from proceeding with the erection of the new electric plant, claiming it to be an infringement upon the Edison three-wire system."

I beg to inform you on behalf of the Siemens & Halske Co. that the above statement is an error. The facts of the case are, that the General Electric Co. obtained a temporary injunction against E. G. Bernard, the contractor, for an alleged infringement of the "Feeder and Main Patent." The Siemens & Halske Co. are in no wise concerned, are not a party to the suit, and have nothing whatever to do with the construction of the plant. So far as the said company are concerned, all that they have done is to have sold three Siemens generators to Mr. Bernard. It is assumed that the Siemens & Halske Co. have a right to sell the machines which since 1867 have borne the name of their inventor.

GEO. H. BENJAMIN, *Atty.*

NEW YORK, Dec. 21, 1893.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 19, 1893.

Alarms and Signals :—

Electric Railway Signal, J. Ortega y Espinosa, Mexico, 511,131. Filed Oct. 26, 1891.

Electrical block system for steam railways.

Signal for Cable Railways, J. Sachs, New York, 511,168. Filed August 4, 1893.

Employs movable circuit controlling devices in the conduit and mechanical appliances moving with the car and brought into action with the controlling devices.

Electric Signaling Device for Hose, G. L. Barnard, Milwaukee, Wis., 511,188. Filed Aug. 29, 1892.

Dynamos and Motors :—

Brush Holder, J. R. Coffman, Detroit, Mich., 510,892. Filed Dec. 9, 1892.

Relates especially to regulating the pressure of the brush against the commutator.

Electric Locomotive, C. F. Winkler, Troy, N. Y., 510,947. Filed March 11, 1893.

Employs two armatures geared respectively with the two car axles, and a single field magnet acting upon both armatures.

Brush Holder for Dynamo Electric Machines, F. E. Averill, Syracuse, N. Y., 510,952, Filed Feb. 13, 1893.

Consists of a frame loosely mounted on a supporting spindle, an arm fixed to the spindle and a spring connected with the arm regulating the pressure of the brush.

Hand Regulator for Electric Motors, W. D. Packard, Warren, O., 511,157. Filed Dec. 8, 1892.

The invention consists in providing a rheostat with clock work mechanism for controlling the operation of the switch arm, a spring impelled wheel, and an electrically operated stop for limiting the movement of the wheel.

Electric Motor, O. F. Conklin, Dayton, O, 511,196. Filed July 6, 1893.

Employs pole pieces inclosing the ends of the field magnet core and having segmental channels in which the armature is adapted to revolve.

Brush Holder for Electric Motors, J. J. Robinson and F. B. Perkins, Toledo, O., 511,214. Filed Feb 6, 1893.

Has for its object especially to guard against the possibility of contact of the metal with the commutator.

Galvanic and Thermo-Electric Batteries :—

Electrical Connector, F. G. Curtis, New York, N. Y., 510,898. Filed Feb. 13, 1893.

Relates to means for connecting primary batteries to one another.

Method of Adjusting the Joints of Carbon Electrodes, E. B. Cutten, New York, 510,899. Filed March 28, 1893.

The method consists in means for indicating the resistance at the joint and then adjusting the parts until a certain definite resistance is indicated.

Electrode for Voltaic Cells, E. B. Cutten, New York, 510,901. Filed May 1, 1893.

Employs a carbon electrode with a glass support, the former being secured to the latter by the material of the support.

Electrode for Voltaic Cells, E. B. Cutten, New York, 510,902. Filed May 1, 1893.

Similar to No. 510,901.

Primary Electric Battery, E. Poppowitsch, Brooklyn, N. Y., 511,159. Filed Dec. 28, 1892.

Employs a packing of saw dust, sea salt, sal-ammoniac, bichromate of potash, granulated manganese and concentrated sulphuric acid.

Thermo-electric Element, M. Mestern, Turin, Italy, 511,245. Filed Apl. 9, 1889.

Consists of a block of iron in contact with a block of alloy composed of zinc and antimony.

Heating :—

Temperature Regulator for Electric Heaters, A. M. Butz, Oak Park, Ill., 510,889. Filed Dec. 24, 1892.

Lamps and Appurtenances :—

Electric Arc Lamp, A. Hormel and G. S. Junginger, New York, 511,049. Filed March 24, 1893.

Employs a hollow electrode and a spirally grooved carbon rack inserted within it, the former provided with pins projecting into the groove of the latter and serving as guides.

Electric Lamp, A. Zobel, Munich, Germany, 511,229. Filed Feb. 15, 1893.

Employs three leading-in wires and two filaments each connected at one end with a common leading-in wire.

Miscellaneous :—

Apparatus for Electrolytically Producing Soda and Chlorine, E. B. Cutten, New York, N. Y., 510,900. Filed March 30, 1893.

Electric Pump, F. W. Merritt, Duluth, Minn., 510,931. Filed Dec. 2, 1892.

Electric Elevator, F. A. Perret, Brooklyn, N. Y., 510,932. Filed Nov. 12, 1892.

Employs in addition to the armature circuit and the field circuit, a third circuit including an apparatus controlling the rheostat in the armature circuit; this third circuit being a direct shunt to the brushes of the motor.

Label Holder, J. H. Shaffer and E. Horowsky, Allegheny, Pa., 511,167. Filed Dec. 21, 1892.

Rheostat, F. A. Weller, Boston, Mass., 511,259. Filed April 20, 1892.

Relates especially to the arrangement of the rheostat within a small compass, and to the proper ventilation of the coils.

Resistance Box, A. O. Benecke, Newark, N. J., 511,286. Filed Sept. 10, 1892.

The combination in a set of resistance coils or bridge of a series of fixed contact plates, a series of resistances respectively interposed between successive contact plates, and circuit connections and means whereby one or more of the intermediate contact plates may be electrically connected with either of the end plates of said series.

Railways and Appliances :—

Electric Railway Switch and Crossing, W. W. Hendrix, Bowling Green, Ky., 511,017. Filed Aug. 5, 1892.

Electric Railway Trolley, W. W. Hendrix, Bowling Green, Ky., 511,018. Filed Aug. 5, 1892.

Employs a guard for the trolley wheel consisting of two jaws closing above the wire and adapted to be forced apart by each hanger and to spring back into position after the hanger has been passed.

Electric Railway Trolley, W. W. Hendrix, Bowling Green, Ky., 511,019. Filed Oct. 7, 1892.

A rotatable trolley pole revolving upon a circular track on the roof of the car.

Electrically Operated Railway Switch, C. A. Stone, Newton, and E. S. Webster, Boston, Mass., 511,173. Filed Aug. 30, 1892.

Closed Conduit Electric Railway, W. S. Smith, Berkeley, Cal., 511,254. Filed Feb. 29, 1892.

Employs junction boxes between the sections of the conductor with ball and socket joints between the conductor and the walls of the boxes.

Switches and Cut-Outs :—

Electric Regulating Switch, E. A. Barber, Watertown, N. Y., 511,187. Filed June 26, 1893.

Has for its object to automatically transfer the energy not needed for operating motors on the main line to suitable resistance coils for absorbing the surplus energy.

Electric Switch, J. L. Hinds, Syracuse, N. Y., 511,240. Filed Nov, 27, 1891.

A snap switch for incandescent circuits.

Telegraphs :—

System of Telegraphy, J. A. Parker, St. Louis, Mo., and L. L. Summers, Chicago, Ill., 510,929. Filed July 30, 1892.

Relates especially to means for increasing the speed and accuracy of the operation of stenographic transmitters.

Telegraphic Relay, E. Weston, Newark, N. J., 511,005. Filed June 4, 1891.

Employs a fixed body of magnetic material disposed in the field of force of the magnet, and a coil of conducting material surrounding the fixed body and supported by pivoted shafts.

Telautograph, R. M. Hunter, Philadelphia, Pa., 511,081. Filed May 26, 1893.

Telegraphic Transmitter, H. F. Stine, Dec'd., Red Bud, Ill., 511,172. Filed May 4, 1893.

A stenographic system of telegraphy.

Morse Transmitter, A. F. M. Cornaud, Brussels, Belgium, 511,234. Filed May 29, 1889.

A stenographic telegraph transmitter sending signals by the Morse code.

Telegraph Relay, E. P. Medina, San Francisco, Cal., 511,244, Filed May 4, 1891.

Telephones and Apparatus :—

Magneto Telephone, J. A. Brown, Moline, Ill., 511,118. Filed Aug. 16, 1893.

The method consists in producing a current in a coil by induction from a magnet by varying the contact of the core of the coil which constitutes a temporary magnet with the permanent magnet.

Two Station Telephone Circuit, F. A. Pickernell, Newark, N. J., 511,276. Filed Aug. 7, 1893.

PERSONAL.

MR. H. A. WAGNER.

MR. H. A. WAGNER, who has for so long been identified with the Missouri Electric Light and Power Company as its superintendent, has, upon the retirement of Mr. James I. Ayer from the Municipal Electric Light Company, assumed the office of general superintendent of this company also. In so doing, Mr. Wagner finds himself responsible for the affairs of two companies, one carrying 110,000 incandescent lamps and the other 4,000 arc lamps. Mr. Wagner also remains as general manager of the Wagner Electric Mfg. Company, and will continue to direct its affairs.

MR. W. J. HAMMER is to marry Miss Alice Maud White on January 3, at the residence of her parents, Mr. and Mrs. T. H. White, 1581 Euclid Avenue, Cleveland, O.

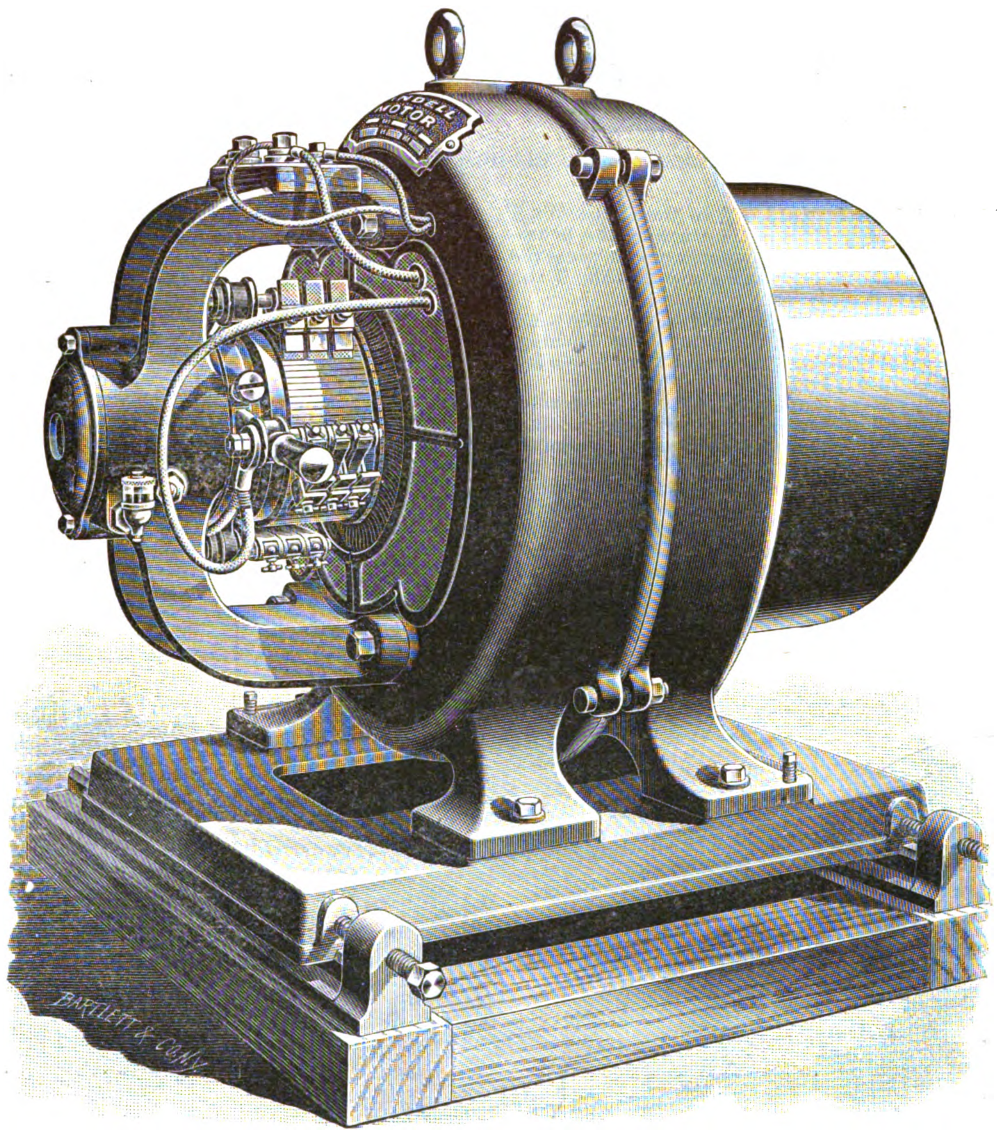
MR. HORATIO A. FOSTER, who is associated with Prof. George Forbes in this country, was married at Chicago on December 22, to Miss Florence Louise, daughter of Mr. and Mrs. Richard Root, of Keokuk, Iowa.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

LUNDELL DIRECT-CURRENT DYNAMOS AND MOTORS.

THE Lundell type of direct-current dynamos and motors is so simple that an elaborate description of the different parts seems to be unnecessary. The chief characteristics are embodied in the novel construction of the field-magnet, whereby a single energizing coil magnetizes all the pole-pieces and a strong protecting shell for the windings of both field and armature forms the magnetic circuit.



THE LUNDELL DIRECT CURRENT MOTOR AND DYNAMO.

The arrangement of the field-magnet and its energizing coil is clearly illustrated in the accompanying engravings.

It will be noted that the two field-magnet halves when bolted together form a shell which completely protects the armature, the whole of the shell being utilized in the magnetic circuit. These field-magnet halves are so designed that they are readily withdrawn from the mould in casting. The cross-section of the shell equals the cross-section of the base of the pole-pieces, so that no choking of the lines of force can occur at any point. Cast steel is employed for all these dynamos and motors. The single energizing coil not only reduces the construction of the machine to the simplest point, but by having only two terminals it is especially adapted to be placed in the hands of inexperienced users, as it avoids any possible mistake in connecting up or any delay or trouble in examination when such becomes necessary. Another feature of the design is that the pole pieces are magnetized directly, and the resistance of the magnetic circuit reduced to a minimum, whereby a considerable economy in the ampere turns of the energizing coil is effected.

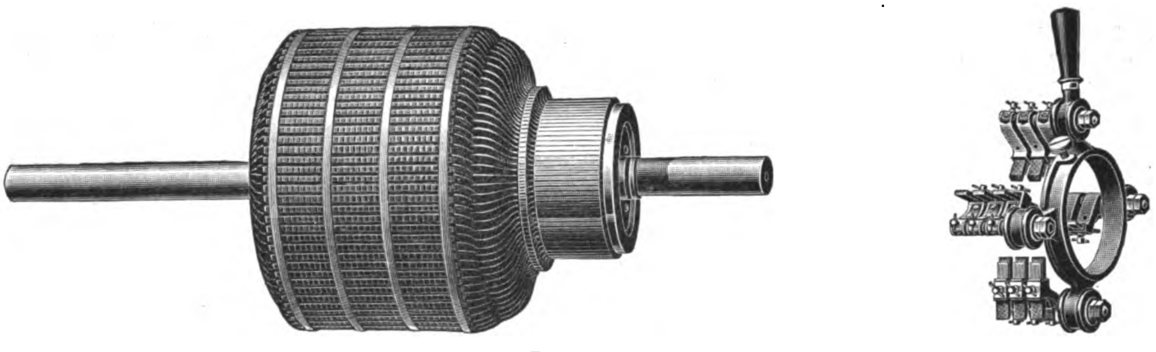
The armature adopted for these machines is of a modern Pacinotti form. This type of armature has in the past been subject to unfavorable criticism on account of the resultant heating of the pole-pieces, but it is now recognized that this heating was not due to the Pacinotti ring itself, but to the lack of knowledge with regard to its proper design. A little reasoning will show that when the ratio of the distance between the teeth and the magnetic gap is too small, a concentration of the lines of force will take place, so that the pole-pieces will be swept over alternately by sections of the highly concentrated lines of force, and by practically inert material. The result is that Foucault currents must inevitably be set up in the pole-pieces and cause the heating, which has been noted in the past. By so proportioning the teeth, however, that the lines of force emanating from the pole-pieces are more evenly distributed over their entire surface surrounding the armature, this abrupt demarcation is avoided, with the result that Foucault currents are also avoided in the pole-pieces.

The result of actual practice with the Lundell machine has shown the soundness of this theory, which is carried into practice by the employment of deep and narrow slots.

Notwithstanding the iron clad nature of the machine, the concentric position of the field-coil allows the armature to be withdrawn without disturbing either the field-coil or the pole-pieces.

The openings around the armature at the ends of the field-magnets are, in the larger machines, covered with metal screens to protect the working parts, and to secure at the same time perfect ventilation. The commutator portion of the armature alone projects outside the screen, and is well protected by a strong bracket which carries the out-board bearing. The brushes are ranged diametrically around the commutator and the opposite brushes are in all four-pole machines connected together. They can be raised from the commutator when the machines are not in use.

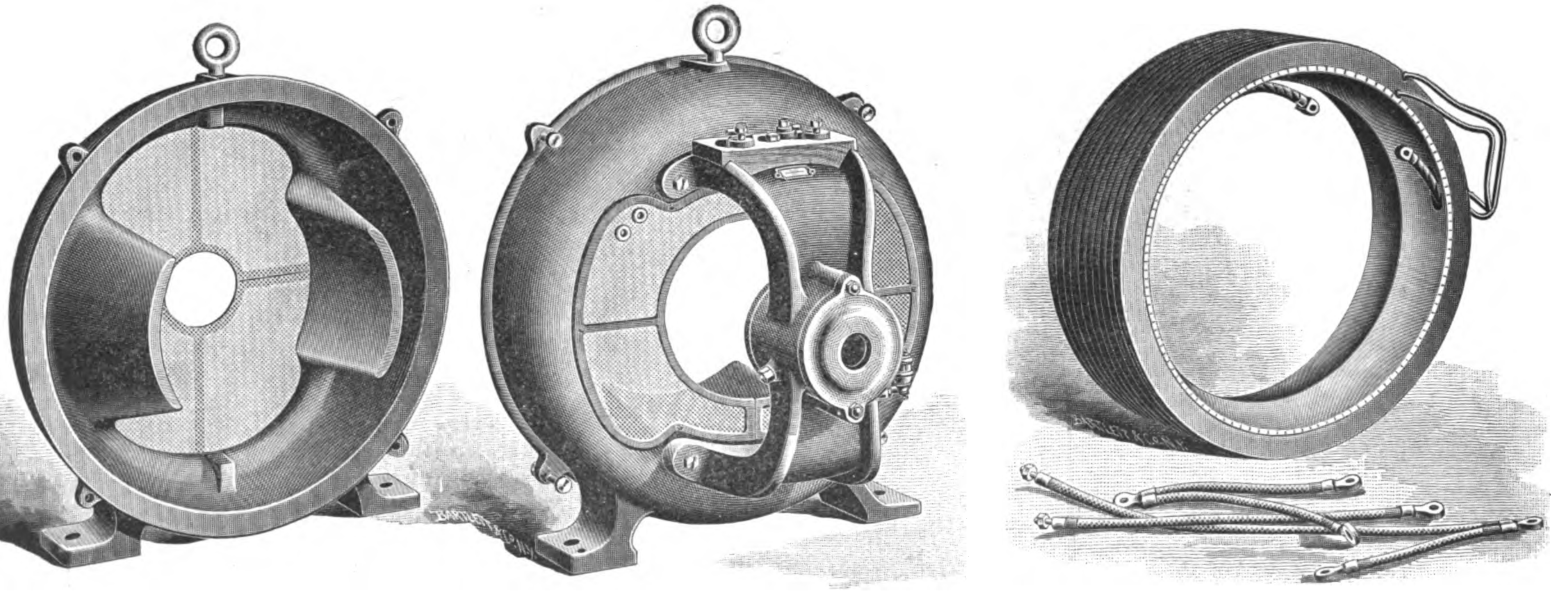
The brushes of the two-pole type have a unique spring arrangement for pressing the carbon brushes against the commutator. The spring has its rear end placed in a curved slot at the end of a brush-holder; while its forward end in the shape of a T presses against the carbon which slides in the ways in the brush-holder. To remove the carbon, it is merely necessary to press the spring upwards out of the slot, which releases it so that the T can be withdrawn, and the carbon slides out.



Armature and Brushes, Lundell Dynamo.

The bearings are constructed with mechanical accuracy, are self-oiling and are provided with a vision gauge. The bushings are made of the best material and are so arranged as to be readily removed and renewed when worn out.

The oiling is accomplished by means of a number of rings which encircle the shaft and dip into the reservoir, thus continually feeding fresh oil to the bearing. In order that the attendant may know the exact condition of the oil, a simple device has been added, consisting of an elbow with an oil-chamber, rising slightly above the normal level of the oil. The vertical arm of this elbow is so arranged that when the visual gauge is half filled the bearing is properly oiled. The glass tube is made so short that by no possible inadvertency can the attendant pour in oil sufficient to flood the bearing and cause the oil to run out at the inner surface of the shaft and so go into the armature.



Field Magnet Halves and Magnetizing Coil, Lundell Dynamo.

The Interior Conduit & Insulation Co., manufacturers of the Lundell dynamos and motors, claim that their efficiency is as high as can be obtained by any first-class machine.

The Southern Pacific Railroad Company will build a new cotton shed at New Orleans, 120 feet wide and 350 feet long. They have placed the contract with the Berlin Iron Bridge Company, of East Berlin, Conn. The building will be entirely of iron, the sides being made with the Wilson patent rolling shutters.

QUEEN & CO.'S TACHOMETERS.

Queen & Co., Philadelphia, have an excellent portable tachometer, by means of which the speed of engines, dynamos and motors can be quickly and accurately determined. It is compact, convenient to handle, and will indicate revolutions up to 3,000 turns per minute. They also have stationary types for permanent attachment. In the economical operation of a lighting or power plant, it is highly necessary to run a dynamo very close to schedule speed, which can only be determined by an instrument such as the above.

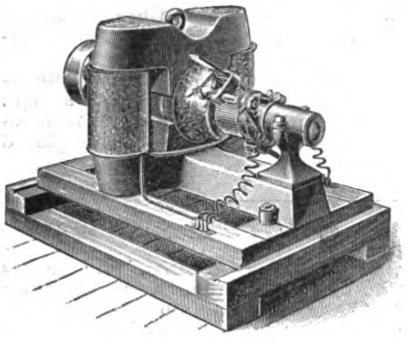
JOHN SCOTT MEDAL AWARDED FOR THE EDSON GAUGE.

The John Scott legacy medal and premium, held in trust by the city of Philadelphia under the legacy of John Scott of Edinburgh, to be used for the encouragement of "ingenious men and women who make useful inventions," provides for the distribution of a medal incribed, "To the most deserving," and money premium in the sum of $20, has just been awarded to Jarvis B. Edson of New York, for his pressure-recording gauge, by the Franklin Institute.

The general adoption of these valuable instruments proves their indispensable nature, for in no other way can a proprietor place himself in a position to know how the steam pressure is carried during night and day, or how much inattention accompanies the firing. As it is a well established fact that carelessness and indifference at the furnace door wastes coal in an amount often sufficient to pay an extra dividend, to say nothing of loss in the cylinder from lack of initial pressure and proper economy from expansion of the steam, for the firemen little understand the necessity for maintaining high initial pressure. "Following" too far or "cut-off" too short, are both wasteful of steam and can only be controlled by the fireman carrying uniformly such a pressure on the boilers as the engine requires for the work it has to perform.

It is equally evident that such records, similarly produced, are as valuable where compressed air, water or other fluids are desired to be maintained under prescribed degrees of pressure.

THE H. C. FISH MACHINE WORKS.



The Fish Dynamo.

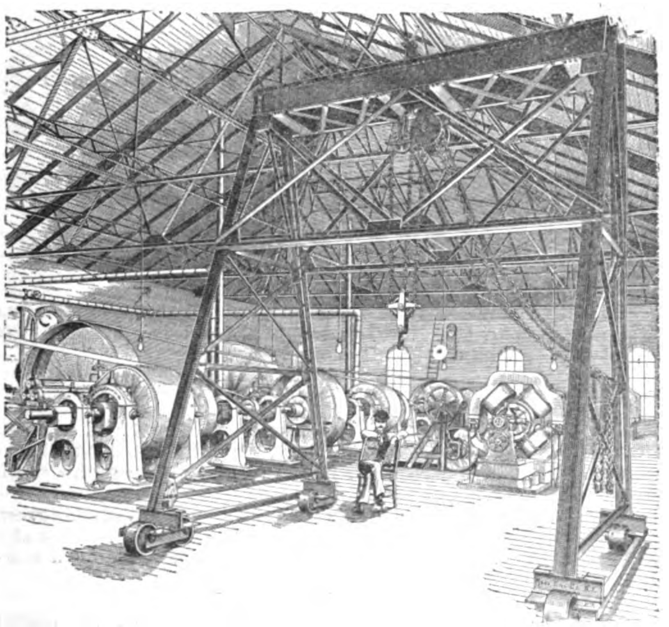
THE H. C. FISH MACHINE WORKS, of Worcester, Mass., have published a catalogue of their new electrical department. After a long time spent in experiment and thorough testing, they are now ready to place on the market electrical machinery of the highest class. The company have maintained an enviable reputation in other branches of business in past years, and expect to preserve that reputation in the future in this new branch.

The accompanying illustration shows the type of their machines ranging from four to eight kilowatts. They have large commutators and very strong fields, and are claimed to be entirely free from sparking. The bearings of the smaller sizes are of phosphor bronze and, in the larger, of compressed Babbitt metal in cast iron shells. These machines do not in any way greatly depart from ordinary accepted engineering practice, but they are claimed to embody all the favorable points possible which modern practice has found reliable. It is unnecessary to recite the points which are necessary to make a good machine as they are well known to all our readers. The company have now, in spite of the business depression, orders ahead for two months.

POWER HOUSE OF NEW ORLEANS AND CARROLLTON ROAD.

THE new electric plant of the New Orleans & Carrollton Railway Co., at New Orleans, La., consists of a car-shed and power-house, both designed and built by The Berlin Iron Bridge Company, of East Berlin, Conn.

The former is 128 feet in width and 300 feet in length. Light for the interior is secured through the side windows in the monitor, ventilation being provided for by means of louvers, the louvers and the windows alternating from panel to panel. The sides of the building for a distance of about 10 feet from the ground are left entirely open so as to admit of free access to the interior of the building. The ends of the car-house are also left open below the tie beams so that cars can be moved in and out without trouble. A building can be constructed in this way at New Orleans on account of the warm climate—it being unnecessary even in the coldest days to protect the interior or to provide for heat.

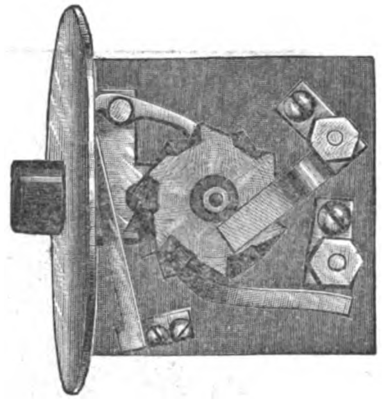


POWER HOUSE OF NEW ORLEANS AND CARROLLTON ROAD.

The power-house shown in the illustration has a construction similar to the car-shed, except that the side walls are of brick, the roof only being of iron. The particular feature, however, of this part of the plant is the portable crane shown in the foreground. This is so arranged that it can be easily moved to any part of the building, and is of sufficient capacity to raise and lower the machinery in and out of place. In the case of this power-house a traveling crane of the full width of the building would be an expensive matter. Owing to the general arrangement of the steam pipes and belts, this construction would be inexpedient and unadvisable. To meet this necessity the crane shown in the illustration was designed and built by The Berlin Company, and has proved a great success. The construction of both buildings is creditable both to the builders and the New Orleans Railroad Co.

"STANDARD" PUSH SWITCH.

THE ELECTRIC APPLIANCE COMPANY, of Chicago, are introducing the latest novelty in switches, known as the "Standard" single push flush switch shown in the accompanying illustrations. The particular feature of the switch is that it is operated by only one button instead of by two as is the case in the ordinary construction of push switches. The advantage of this method of operation is readily apparent not only in the added neatness of the switch but in its simplicity of action.



"STANDARD" PUSH SWITCH.

The interior construction of the switch is shown in the cut. The action, which is readily apparent, is very positive and at the same time the switch can be manipulated with great ease. The break is quick and is made in such a manner that the switch cannot be left half off or on and a short circuit cannot occur.

The "Standard" single push switch is intended to take the place of any 5 or 10 ampere snap or flush switch, and is made in the regular 10 ampere single pole, and 10 ampere three way styles. A third style is now under way and will shortly be ready for the market, to be known as the "Standard" commutation switch. In general appearance it is the same as the regular switch shown here but the contacts are so arranged that a light or group of lights by the use of the commutation switch can be controlled from any number of points without extra wiring; that is, a light or group of lights can be turned on or off from any three or more points independently.

All of the "Standard" switches are very compact and neatly made, no money being spared to make them first-class in every respect. The price at which the Electric Appliance Company are placing them on the market is also very low. Large numbers have already been sold and the demand is rapidly increasing.

THE WESTERN TELEPHONE CONSTRUCTION CO.

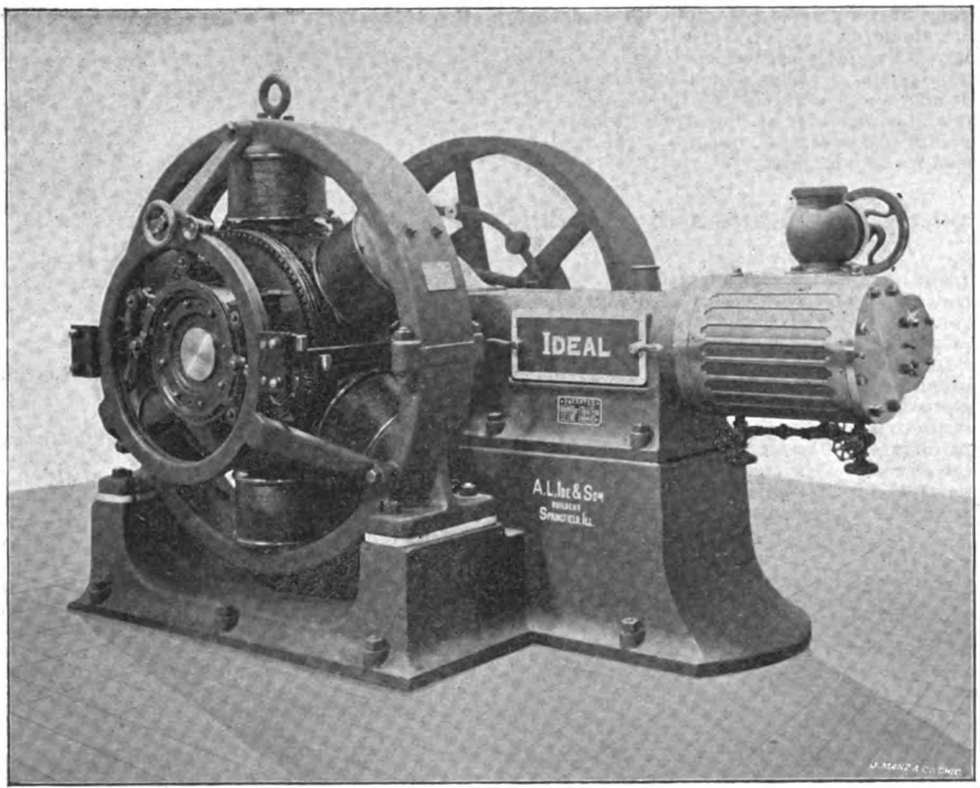
THE WESTERN TELEPHONE CONSTRUCTION CO., of 440 Monadnock Building, Chicago, who have been for the past year making preparations to enter the telephone field on a large scale as soon as the telephone patents had expired sufficiently to warrant them in so doing, will begin extensive operations on or about the first of next month.

This company, by purchase and otherwise have obtained control of some of the most valuable devices in telephonic apparatus, including everything necessary for the complete installation of first-class modern telephone exchanges, as well as complete outfits for cities, towns and villages, private lines or factory plants. They control nearly 100 patents, and contemplate dealing exclusively in telephonic apparatus.

Contracts will be made for the sale outright of the entire equipments or any portion of the apparatus necessary for a telephone plant and the company's factory facilities and financial recources make it possible for them to operate on an extensive scale. A number of large contracts have already been obtained.

ELECTRIC LIGHTING COMBINATION FOR THE SOUTHERN HOTEL, ST. LOUIS.

THE state of perfection at which the latest types of steam engines have arrived is shown in nothing so clearly as in the increased demand for automatic types of engines to be directly connected to dynamos. The fluctuations in load, especially in street car service, are so great and so numerous—fluctuations of 25 to 100 per cent. of the entire load, occurring almost instantaneously, that it has taxed the inventive genius of our engine builders to the utmost to produce engines that will stand the strain. In the case of belt-driven dynamos, a severe short circuit will usually cause the belt to fly off and thus relieve the engine, but a direct connected engine must not only be able to maintain a uniform speed under these sudden changes of load, but it must not fly to pieces if a short circuit brings the engine to a sudden stand-still.



IDE ENGINE COMBINATION PLANT IN THE SOUTHERN HOTEL, ST. LOUIS.

That the day of slow-speed engines with bursting fly wheels is past for electrical work is freely claimed. Where space is not very valuable, dynamos belted to high speed engines will continue to be used, but where space becomes a matter for grave consideration, the future demand must be for direct connected engines as soon as engine builders can supply a suitable engine.

To meet this demand, the engine shown in the accompanying cut has been built by A. L. Ide & Son, of Springfield, Ill. The illustration is taken from one of three ideal engines recently shipped by this firm for use in lighting the new Southern Hotel in St. Louis, Mo. Two of these engines had 14x14 cylinders, the third had a 13x12 cylinder. All were regulated to run at 275 revolutions. Each of these engines had a General Electric Co. armature keyed on the crank shaft in place of the plain pulley. The construction of the armature and engine are such that no outboard bearing is required. The two 14x14 engines are to drive dynamos belted from the governor pulleys in addition to the direct connected armatures.

The points of superiority claimed by the builders of these engines for this form are as follows: They claim that they will not vary over 1 per cent. in speed for a sudden change of 100 per cent. in load. They are perfectly self-contained and balanced. Every engine was adjusted before leaving the works to run at its specified speed under full load, and so balanced as to run without shaking with all anchor bolts removed. Excellence in workmanship and material—steel and bronze entering into its construction to an unusual extent. The engines are provided with the well-known Ideal system of self-oiling, which supplies all the working parts with a constant stream of oil that is used over and over again. There is positively no oil scattered in any direction. The armatures are therefore entirely free from any danger that could result from a splash of oil. That these engines are peculiarly adapted to work in places where space is valuable, will be apparent from those dimensions:

The 14x14 engines, with armatures attached complete as shown in the illustration, can be placed in a box 68 inches high, 81 inches wide, 10 feet and three inches long, and their rated horse power is 125. The 13x12 engine—100 h. p.—can be placed in a box 68x74x9 feet and 11 inches.

THE "WHITE PLUME" OF KERITE.

MR. W. R. BRIXEY is "nothing if not original," and he has just given another proof of his fertility of resource in presenting to the friends of "Kerite" a beautiful aluminum pen as a New Year memento. It is stamped out in the shape of an old-fashioned quill, and has the word "Kerite" in large letters on the plumage, together with the injunction to specify that insulation whenever any wire orders are to be given out. The pen is curiously bright, light and pretty, and will be warmly welcomed by every lucky recipient. We have no doubt that requests for an exemplar, sent to Mr. Ham, at the headquarters of Kerite, 203 Broadway, will be courteously complied with.

CHRISTMAS CALENDARS.

THE DIRECT U. S. CABLE CO. has issued a neat pad calendar from its headquarters at 40 Broadway. It is mounted on a handsome lithographed card, which shows Puck putting his girdle around the earth.

THE COMMERCIAL CABLE CO.'s staff has issued seasonable greetings in the shape of a fine picture of the "Vigilant" surrounded by a horseshoe. It is printed on heavy board, and is a work of art.

MR. S. A. DOUGLAS has resigned his connection with the Brush Electric Company whose Western manager he has been for some time past and has become general sales agent of the General Incandescent Arc Light Co., of 572 to 578 First Ave., New York.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XVII. JANUARY 10, 1894. No. 297.

THE TESLA ELECTRICAL OSCILLATOR.

IN the lecture delivered before the Chicago Electrical Congress, Mr. Nikola Tesla first drew attention[1] to the method and means which he had devised for the continuous production of alternating currents of constant period in which all rotating parts are avoided by the employment of his oscillating engine directly to the movement of the generating coil in the magnetic field.

The main reason why no engine heretofore has been capable of producing results of this nature is that it has been customary to connect with the reciprocating parts a heavy fly-wheel or some equivalent rotary system of relatively very great inertia, or in other cases where no rotary system was employed, as in certain reciprocating engines or tools, no regard has been paid to the obtainment of the conditions essential to the end which Mr. Tesla had in view.

In applying the Tesla oscillator for the generation of currents of constant period certain conditions are encountered which must be taken into consideration in order to satisfactorily secure the desired result. When a conductor is moved in a magnetic field and a current caused to circulate therein, the electromagnetic reaction between it and the field might disturb the mechanical oscillation to such an extent as to throw it out of isochronism. This, for instance, might occur when the electromagnetic reaction is very great in comparison with the power of the engine, and there is a retardation of the current so that the electromagnetic reaction might have an effect similar to that which would result from a variation of the tension of the spring; but if the circuit of the generator be adjusted so that the phases of the electromotive force and current coincide in time, that is to say, when the current is not retarded, then the generator driven by the engine acts merely as a frictional resistance and will not, as a rule, alter the period of the mechanical vibration, although it may alter its amplitude. This condition may be readily secured by properly proportioning the self induction and capacity of the circuit including the generator.

Mr. Tesla has, however, observed the further fact in connection with the use of such engines as a means for running a generator, that it is advantageous that the period of the engine and the natural period of electrical vibration of the generator should be the same, as in such case the best conditions for electrical resonance are established and the possibility of disturbing the period of mechanical vibrations is reduced to a minimum. Mr. Tesla has found that even if the theoretical conditions necessary for maintaining a constant period in the engine itself are not exactly maintained, still the engine and generator combined will vibrate at a constant period. For example, if instead of using in the engine an independent cylinder and plunger, as an air spring of practically constant rigidity, the piston may impinge upon air cushions at the ends of its own cylinder. Although the rigidity of such cushions or springs might be considerably affected and varied by the variations of pressure within the cylinder, still by combining with such an engine a generator which has a period of its own, approximately that of the engine, constant vibration may be maintained even through a considerable range of varying pressure, owing to the controlling action of the electromagnetic system.

Indeed Mr. Tesla has even found that under certain conditions the influence of the electromagnetic system may be made so great as to entirely control the period of the mechanical vibration within wide limits of varying pressure. This is likely to occur in those instances where the power of the engine, while fully capable of maintaining a vibration once started, is not sufficient to change its rate.

In our issue of November 8, 1893, we gave the details of construction of the Tesla oscillator and a patent just issued to Mr. Tesla now enables us to supplement our previous descriptions with those of other types employed by him in this work. The accompanying engraving, Fig. 1, is a sectional view of an oscillator fulfilling the conditions laid down above.

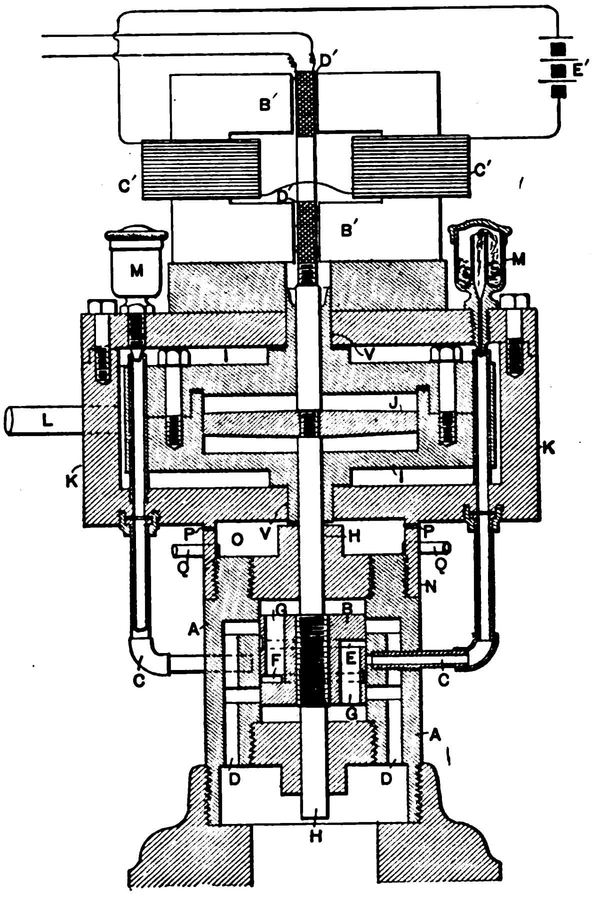


FIG. 1.—TESLA ELECTRICAL OSCILLATOR.

Referring to Fig. 1, A is the main cylinder in which works a piston B. Inlet ports C C pass through the sides of the cylinder opening at the middle and on opposite sides. Exhaust ports D D extend through the walls of the cylinder and are formed with branches that open into the interior of the cylinder on each side of the inlet ports and on opposite sides of the cylinder. The piston B has two circumferential grooves E F which communicate through openings G in the piston with the cylinder on opposite sides of the piston respectively.

---

[1] See The Electrical Engineer, August 30, 1893.

The particular construction of the cylinder, the piston and the ports controlling it may be very much varied, and is not in itself material, except that in the special case under consideration it is desirable that all the ports, and more especially the exhaust ports, should be made very much larger than is usually the case so that no force due to the action of the steam or compressed air will tend to retard or affect the return of the piston in either direction.

The piston B is secured to a piston rod H which works in suitable stuffing boxes in the heads of the cylinder A. This rod is prolonged on one side and extends through bearings V in a cylinder I mounted in line with the first, and within which is a disc or plunger J carried by the rod H. The cylinder I is without parts of any kind and is airtight except as a small leakage may occur through the bearings V, which experience has shown need not be fitted with any very considerable accuracy.

The cylinder I is surrounded by a jacket K which leaves an open space or chamber around it. The bearings V in the cylinder, extend through the jacket to the outside air and the chamber between the cylinder and jacket is made steam or air-tight by a suitable packing. The main supply pipe L for steam or compressed air leads into this chamber, and the two pipes that lead to cylinder A run from this chamber, oil cups M being conveniently arranged to deliver oil into the pipes for lubricating the piston.

In the particular form of engine shown, the jacket K which contains the cylinder I is provided with a flange N by which it is screwed to the end of the cylinder A. A small chamber O is thus formed which has air vents P in its sides and drip pipes Q leading out from it through which the oil which collects in it is carried off.

In the position of the parts shown, or when the piston is at the middle point of its stroke, the plunger J is at the centre of the cylinder I and the air on both sides of the same is at the normal pressure of the outside atmosphere. If a source of steam or compressed air be then connected to the inlet ports C C of the cylinder A and a movement be imparted to the piston as by a sudden blow, the latter begins to reciprocate in the well-known way.

The movements of the piston compress and rarefy the air in the cylinder I at opposite ends, alternately. A forward stroke compresses the air ahead of the plunger J which acts as a spring to return it; similarly, on the back stroke the air is compressed on the opposite side of the plunger J and tends to drive it forward.

The compressions of the air in the cylinder I and the consequent loss of energy due mainly to the imperfect elasticity of the air, give rise to a very considerable amount of heat. This heat is utilized by conducting the steam or compressed air to the engine cylinder through the chamber formed by the jacket surrounding the air-spring cylinder, the heat thus taken up and used to raise the temperature of the steam or air acting upon the piston is availed of to increase the efficiency of the engine.

In any given engine of this kind the normal pressure will produce a stroke of determined length, and this will be increased or diminished according to the increase of pressure above, or the reduction of pressure below, the normal. In constructing the apparatus proper allowance is made for a variation in the length of stroke by giving to the confining cylinder I of the air spring properly determined dimensions. The greater the pressuse upon the piston, the higher will be the degree of compression of the air-spring, and the consequent counteracting force upon the plunger.

The rate or period of reciprocation of the piston, however, is mainly determined by the rigidity of the air spring and the inertia of the moving system, and any period of oscillation within very wide limits may be secured by properly proportioning these factors, as by varying the dimensions of the air chamber, which is equivalent to varying the rigidity of the spring, or by adjusting the weight of the moving parts. These conditions are all readily determinable, and an engine constructed as above described maintains a perfectly uniform period through very wide limits of pressure.

The pressure of the air confined in the cylinder when the plunger I is in its central position will always be practically that of the surrounding atmosphere, for while the cylinder is so constructed as not to permit such sudden escape of air as to sensibly impair or modify the action of the air-spring, there will still be a slow leakage of air into or out of it around the piston rod, according to the pressure therein, so that the pressure of the air on opposite sides of the plunger will always tend to remain at that of the outside atmosphere.

To the piston rod H is secured a coil D′ which, by the movements of the piston, is oscillated in the magnetic field produced by two magnets B′ B′ which may be permanent magnets or energized by coils C′ C′ connected with a source of continuous current E′. The movement of the coil D′ across the lines of force established by the magnets gives rise to alternating currents in the coil. These currents, if the period of mechanical oscillation be constant will be of constant period.

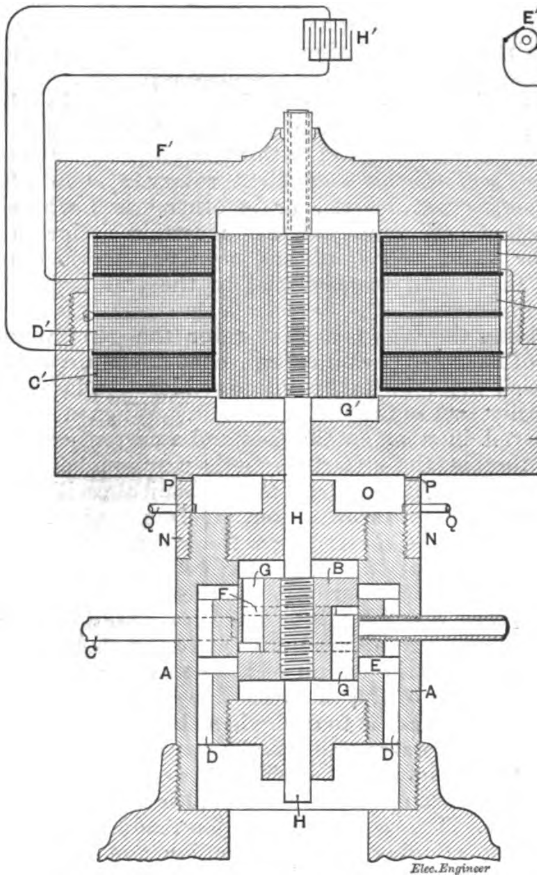

FIG. 2.—TESLA ELECTRICAL OSCILLATOR.

In the case under consideration it is assumed as a necessary condition that the inertia of the movable element of the generator and the electromagnetic reaction which it exerts will not be of such a character as to materially disturb the action of the engine.

Fig. 2 is an example of a combination in which the engine is not of itself capable of determining entirely the period of oscillation, but in which the generator contributes to this end. In this figure the engine is the same as that shown in Fig. 1. The exterior air spring is however omitted and the air spaces at the ends of the cylinder A relied on for accomplishing the same purpose. As the pressure in these spaces is liable to variations from variations in the steam or gas used in impelling the piston they might affect the period of oscillation, and the conditions are not as stable and certain as in the case of an engine constructed as in Fig. 1. But if the natural period of vibration of the electric system be made to approximately accord with the average period of the engine such tendencies to variation are very largely overcome and the engine will preserve its period even through a considerable range of variation of pressure.

The generator in this case is composed of a magnetic casing F′ in which a laminated core G′ secured to the piston rod H is caused to vibrate. Surrounding the plunger are two exciting coils C′ C′, and one or more induced coils D′ D′. The coils C′ C′ are connected with a generator of continuous currents E′ and are wound to produce consequent poles in the core G′. Any movement of the latter will therefore shift the lines of force through coils D′ D′ and produce currents therein.

In the circuit of coils D′ is shown a condenser H′. By the use of a proper condenser the self-induction of this circuit may be neutralized. Such a circuit will have a certain natural period of vibration, and, as this depends upon the capacity and self induction, the period may be varied to approximately accord with the period of the engine.

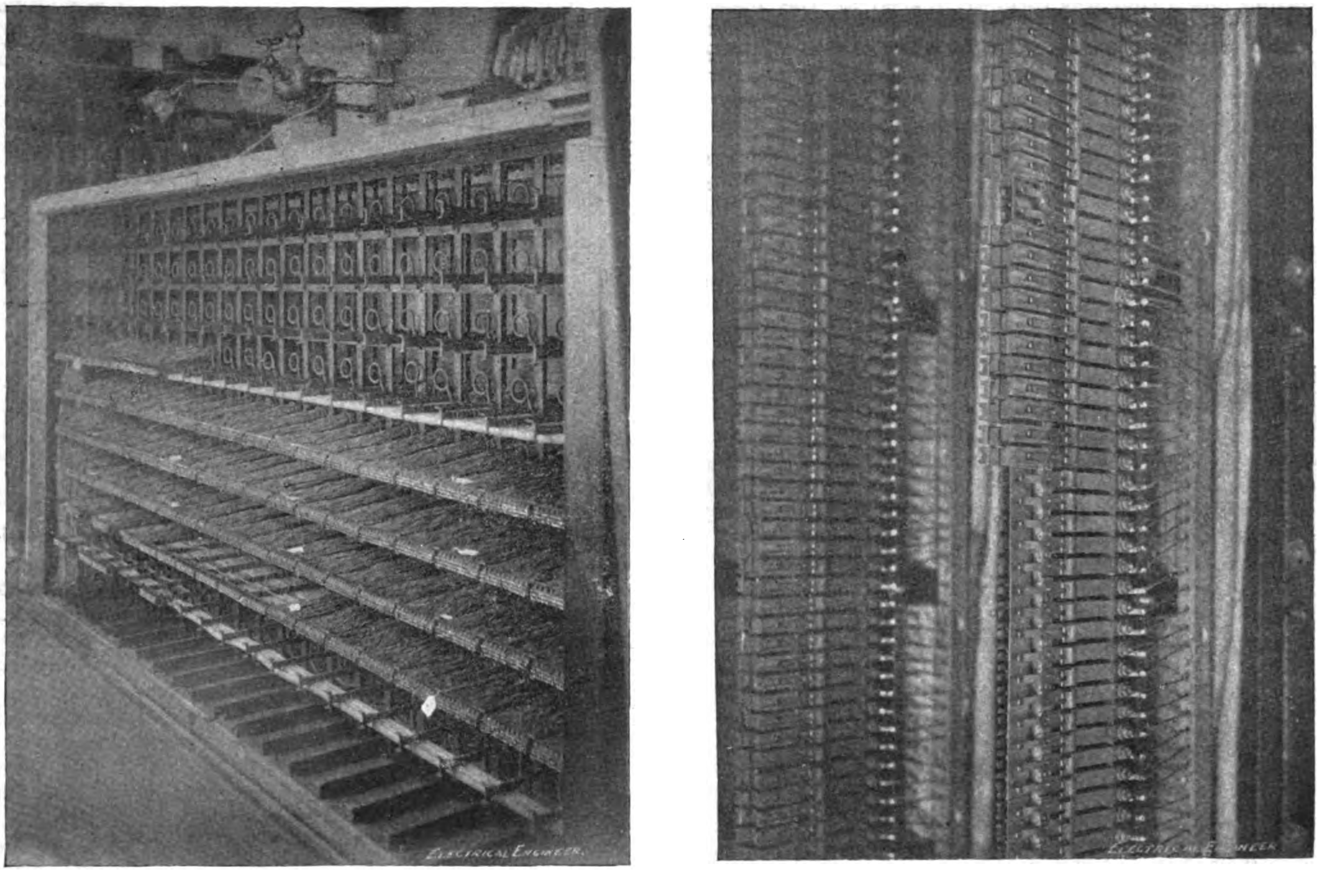
In case the power of the engine be comparatively small, as when the pressure is applied through a very small fraction of the total stroke, the electrical vibration will tend to control the period, and it is clear that if the character of such vibration be not very widely different from the average period of vibration of the engine under ordinary working conditions that such control may be entirely adequate to produce the desired results.

THE NEW BROAD STREET TELEPHONE EXCHANGE IN NEW YORK.

The Broad Street Exchange is the eighth central office that the Metropolitan Telephone and Telegraph Company has established in New York City below the Harlem River. It serves the financial and importing district bounded by Wall street and Broadway, from Wall street to the Battery. At present it contains some eleven hundred subscribers and has an actual capacity for 1,500 lines, and an ultimate capacity for 3,000 lines

The entire building and its electrical equipment represent in every detail the latest and most up-to-date development of telephone engineering. The building is fireproof, and was constructed especially for telephone purposes; it is the fourth of its kind erected by the Metropolitan Company, the other three being at Cortlandt, Spring and 38th streets. The subscribers' lines enter the building through the basement, 55 cables being led in from the subways, each cable containing 50 pairs of conductors. The cables are taken up a shaft in the northerly wall of the building to the terminal room on the seventh story, which is entirely occupied by the different departments of the telephone exchange. In the terminal room the cable heads are mounted on iron racks, and connection is made by means of a cross-connecting frame, between the subscribers' lines and the switchboard cables. At this point the lightning and strong-current protectors are inserted in the circuit; the protectors are carried on special attachments at one side of the distributing rack. They consist of air space cut-outs, which ground the line when the pressure reaches 300 volts, and strong-current protectors which fuse within 30 seconds under the influence of a current of .28 ampere. These appliances efficiently protect the switchboard apparatus against any possibility of damage from foreign currents.

In the terminal room is placed the generating plant

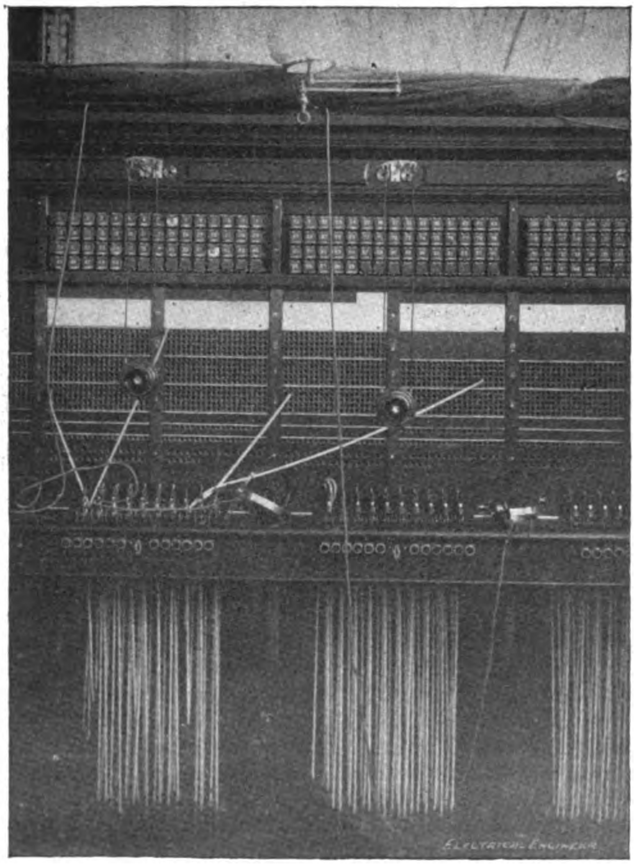


THE DISTRIBUTING RACK AND LIGHTNING ARRESTERS AT THE NEW BROAD STREET TELEPHONE EXCHANGE, NEW YORK.

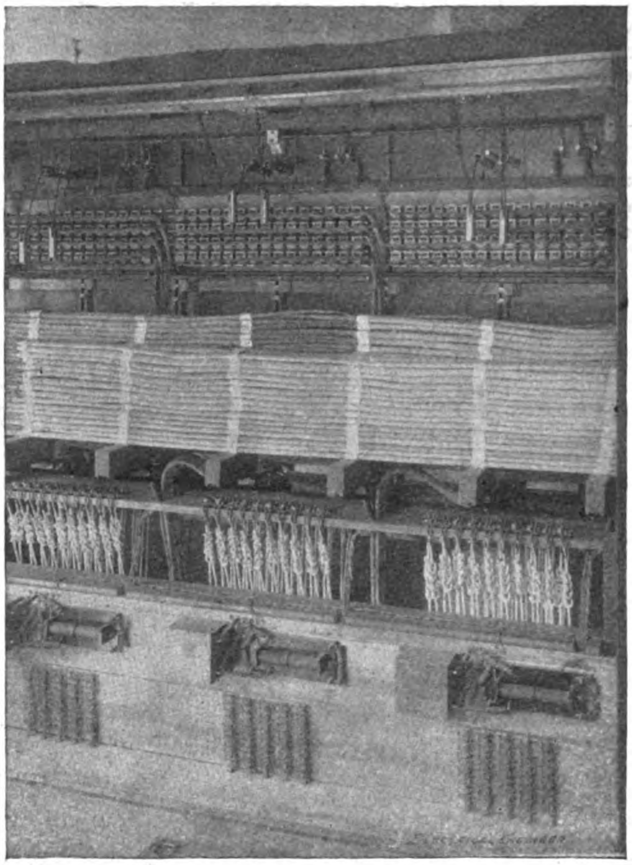
which furnishes current for ringing the subscribers' bells, for operating the switchboard transmitters and the busy signals, and for the relays used in testing the lines. No primary batteries are used in the exchange for any purpose. The ringing current is furnished by motor generators which receive a direct and deliver an alternating current to a circuit connected to the operators' ringing keys on the switchboard, the two windings being on the same armature. The relay current is supplied by a small direct current motor generator and another larger machine of the same type is used for charging the storage batteries by which the switchboard transmitters and the busy signal are operated. The desk of the wire chief, equipped with apparatus for testing lines, occupies one corner of this room.

In the operating room proper is the intermediate distributing rack at which the connections between the answering jacks and line drops and the subscribers' lines are made. This rack takes the place of the intermediate distributing board that was formerly placed at the back of the switchboard itself, and provides a very much more convenient system of effecting the necessary grouping and interchanging of subscribers' lines with reference to the switchboard.

The switchboard itself is of the type known as the "bridging" board, in which all the spring jacks and annunciators are connected in bridge or multiple arc. This preserves the balance of the line in the switchboard. The "busy" signal is effected by means of a circuit entirely distinct from the subscribers' wire; this circuit is normally open, but is closed by a collar on the plug when a connection is put up, current then being thrown on the corresponding spring jacks in the other sections of the board. The indicator drops, both line and clearing out, are of the self-restoring pattern. The line drop is restored by a locking coil that is energized when the operator inserts her plug in the answering jack, and the clearing-out drop is restored in a similar way by the depression of the listening key when the operator cuts in to make sure that the connection is to be taken down. The self-restoring drops relieve the operator of two movements in handling a connection, and are therefore quite a factor in increasing the rapidity of the service.



Front View of the Switchboard.



Rear View of Switchboard Showing Induction Coils.

In general appearance the switchboard is a noticeable improvement over that of the type of a few years ago. It is more compact in every way and has altogether a less overpowering air of complication. The amount of wiring and connections at the back of the board is less than it formerly was, owing to the concentration of the intermediate distributing board in one place. The switchboard transmitters are of the "solid back" type, with the metal case in a dull finish to avoid dazzling the eyes of the operators; the induction coils are placed at the back of the board.

The operating room is extremely spacious, and the whole of the switchboard is in sight at any point in the room. The manager's desk and that of the monitor operator, both equipped with lines running to various parts of the board, are placed about halfway down the room and from them an unobstructed view can be obtained of the entire switchboard and operating force. A large room looking out on the East River is provided for the use of the operators when off duty. This room is handsomely fitted up with tables, chairs, couches, lockers, refreshment urns and all possible arrangements for the comfort of the operators.

The equipment of the Broad Street Exchange has been carried out jointly by the Western Electric Company and the Metropolitan Telephone Company, the latter having done far more of the work than has usually been the practice of telephone companies in regard to such installations. The switchboard was constructed and equipped by the Western Electric Company, as were also the intermediate distributing board and protector rack. The rest of the work, including the desks of the wire chief, monitor operator and manager, the generating plant, the underground cable plant and wiring and many minor details, was carried out by the staff of the Metropolitan Company, the entire job being governed by the plans and specifications of the engineering department. The thoroughly workmanlike and shipshape appearance of all departments of the exchange reflects great credit on the staffs of both companies.

The transfer of subscribers from Cortlandt to Broad was begun on Saturday afternoon, December 30, and completed on the following day. On the first day of the year the new office was completely ready for business, but there was absolutely no business to do; the exchange was almost as quiet as an empty church. On the following day, however, the traffic was exceptionally heavy and lasted at high pressure until unusually late in the day. Both operators and apparatus stood the strain well; even to a practiced observer there was nothing to indicate that the office had not been working for a year and a day instead or for a day only, and in spite of the severity of the test no single case of "trouble" was developed in any part of the system.

On the afternoon of Jan. 3 a large number of visitors inspected the new exchange at the invitation of the Metropolitan Telephone and Telegraph Company.

THE WESTINGHOUSE PLANS FOR THE NIAGARA CONTRACT.

THE work now being done in connection with the electrical utilization of Niagara is attracting universal attention, and public interest has again been greatly stimulated by the paper read before the English Institution of Electrical Engineers, by Prof. George Forbes, and reprinted and discussed in our pages. We now have the pleasure of printing a very important communication on the subject from Mr. L. B. Stillwell, electrical engineer of the Westinghouse Electric and Manufacturing Company, signed by him on behalf of the company.

"We have read the leading editorial on 'The Niagara Project' in THE ELECTRICAL ENGINEER of December 20th, and note with interest the following:

> It was hardly to be expected that the promoters of the Niagara enterprise would accept the individual opinion of any one man on the various points of prominent importance, which had to be considered, and Prof. Forbes' paper may therefore be looked upon as a fair representation of the views of the most advanced electrical engineers, as well as the results of Prof. Forbes' own careful study of the literature on the subject and information gained from other sources. The paper may thus be considered not less an expression of the author's personal opinion than an epitome of the views of a large number of prominent electrical and mechanical engineers, and, as such, it will be of interest to determine in how far these views have been applied at Niagara.

"The fact that the engineers and electricians of the Westinghouse Electric and Manufacturing Company have for several years devoted much attention to the subject of power transmission is well known, as is also the fact that our company has received from the Cataract Construction Company the order for the initial installation of electrical apparatus at Niagara. It seems, therefore, a fair inference that you intend to include the engineers of this company among the electrical engineers of whose views you assume that Prof. Forbes' paper is a fair representation.

"The system which has been adopted for the installation at Niagara Falls is simply the Tesla polyphase system as developed by the technical staff of the Westinghouse Electric and Manufacturing Company. It has not been modified in any particular by the engineers of the Cataract Construction Company or of the Niagara Falls Power Company. It is fully described in publications of this company and was demonstrated on a large scale by one of our exhibits in the Electricity Building at the recent Columbian Exposition in Chicago. In developing and perfecting the system, we have not only been guided by a wide experience in the design, manufacture and use of electrical machinery but we have carried out a large amount of experimental work, much of it on an extensive scale, and have made a careful, theoretical and practical study of the subject. Prof. Forbes' views, as stated in his paper, are naturally in accord with ours upon many points. In others, his paper fails to fully state the facts as we see them, and, in others still, we think his views are incorrect. We cannot, therefore, in justice to our company, consent to the assumption that his paper be accepted as a "fair representation" of our views.

"Some of the technical journals have apparently received the impression that the generator described in Prof. Forbes' paper under the heading "General Description of a 5,000 H. P. Alternator" is that which has been adopted by the Cataract Construction Company. This is not the case. The drawings and specifications of the generator, which Prof. Forbes describes were laid before us in August last, and were fully explained by Dr. Coleman Sellers and Prof. Forbes. After careful consideration, we accepted the general mechanical features of the construction proposed as excellent, but, in the opinion of our electricians and engineers, the electrical features—the method of winding, the insulation, etc.—were impracticable, and realizing that we could not undertake the construction of such a machine with credit to our company, we declined to submit proposals. We were thereupon requested by the officers of the Cataract Construction Company to submit our own plans and specifications and this was done early in August. We followed closely the mechanical features approved by Dr. Sellers but the electrical features are wholly our own. These plans were accepted by the Cataract Construction Company and are those under which the generators for Niagara are now being constructed.

"Prof. Forbes is undoubtedly qualified to speak with authority as to the assumptions and reasoning which have led him to agree with other engineers of the Cataract Construction Company in recommending to his Board of Directors the adoption of the system, which has been selected, but the premises and the reasoning which guided the engineers of the Westinghouse Electric and Manufacturing Company in the development of the Tesla polyphase system, as it will be used at Niagara, differ widely in some respects from those which are set forth in the paper to which your editorial refers.

"We trust that you will give to this explanation suitable prominence as we are unwilling, for the reasons stated, to have Prof. Forbes' paper accepted by your readers as a statement of our views."

THE BUCKEYE LAMP WITHOUT LEADING-IN WIRES.

The Buckeye Electric Co., of Cleveland, have just brought out a most ingenious and novel form of incandescent lamp, which they consider entirely non-infringing, while possessing all the virtues and good qualities of the old, well known Buckeye. It is intended to avoid, among other things, the drawbacks of the so called "gas" lamps, and the objections due to the use of a resinous seal. The features of the lamp may be briefly enumerated as follows:—It consists, first, of an all glass globe and has a perfect vacuum, as so understood in lamp parlance. The familiar Buckeye filament is used in it. It contains no platinum whatever. Most striking of all, it has no leading in wires through the glass. As a matter of fact, the glass stem to which the filament is attached is so treated in the process of manufacturing the lamp as to form in itself an electrical conductor or bridge between the outside and the inside of the lamp. This lamp is now being made in large quantities for the market, and seems to us likely to command a large amount of attention.

THE ELECTRO-MAGNET; or JOSEPH HENRY'S PLACE IN THE HISTORY OF THE ELECTRO-MAGNETIC TELEGRAPH.—II.

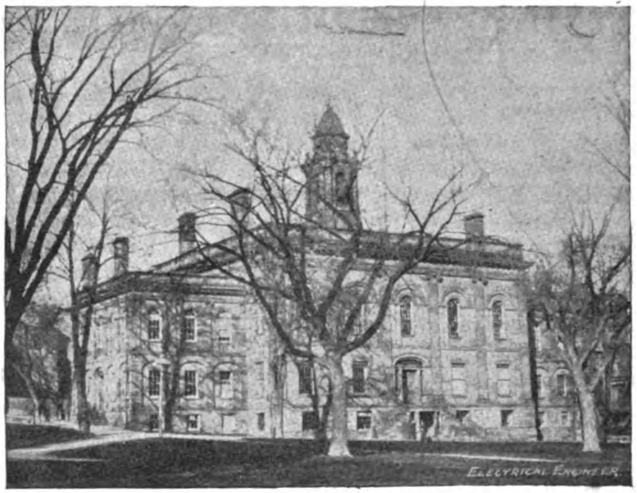
BY

Mary A. Henry

BARLOW was right, the electro-magnetic telegraph was impossible when he made his discouraging assertion in regard to its impracticability. At the time he made that declaration a telegraph founded upon the electro-magnet was bound to be a failure, for the electro-magnet was not the instrument which could meet the demands for the telegraph, until Henry had taken it up and turned it into the sensitive magnet, which could respond to electrical influence at a distance. Until this instrument was made by Henry, the electromagnetic telegraph was an impossibility. The experimental telegraphic efforts founded upon electro-magnetism *prior to Henry's discoveries*, constituted a third era in the history of the telegraph They began shortly after Oersted's discovery that a magnetic needle was deflected when a wire, through which a galvanic current was passing was held above it. Schweigger of Halle, as we know, extended the discovery of Oersted, by bending the wire in several convolutions around the needle, increasing in this way the effect of the current and producing greater deviation of the needle. On this principle he made what is called his "multiplier," or the galvanometer. We give a sketch of it as it is represented in various electrical books—a wooden frame, the magnetic needle within it free to move, and around the frame several convolutions of the wire conducting the electrical current; we will have occasion to refer to the instrument again in this chapter. La Place was the first to suggest that the deflecting power of the electric current might be employed for telegraphic purposes and Ampere was the first to propose a plan for the practical application of this idea; then followed many very interesting attempts to make the moving needles speak for man at a distance. But the action of the wire transmitting the electrical current, which was coiled around the needle and necessary to move it, depended upon the same law which controlled the action of the electro-magnet. This law had not been discovered; was to be discovered by Henry Soon it was found that the deflection of the needles, like the action of the magnet, decreased with the increase in length of the galvanic circuit; the electromotive power failed to act at any great distance. How curious it is to see all these telegraphic efforts—whether founded upon static or frictional electricity, galvanism or electromagnetism, all starting with brilliant eclat, winning deserved admiration, all meeting the same fate, coming to the same apparently insurmountable obstacle,—the failure of the electric force. Some of them were actual working telegraphs, in the sense that they conveyed intelligence at short distances; eight, ten, even twenty miles perhaps, but as regards what in contradistiction to them we have called *the telegraph*, with which man might encircle the world, what did they do? They each and all in various ways only confirmed the same fact, that electricity might be made to produce mechanical effects, which could be used as telegraphic signals. They did not solve the problem how electricity could be made to produce these effects at a distance. They provided ingenious methods for the delivery of the message but did not secure the messenger. The Spirit of the storm was not yet bound to this service.

Sturgeon's magnet had been in his cabinet for four years when young Henry took it up; but, before we see what he did with it, it may not be amiss to follow the steps which led him to it. Let us go back to the year 1824, when it grew into being under Sturgeon's hands, and on the evening of October 30th of that year look into a room in the Albany Academy, where the Albany Institute is holding one of its regular meetings.[1] The president of the Society is the Patroon of Albany, Gen. Van Rensselaer, and as he is very regular in his attendance on its meetings we may suppose he is present on this particular occasion. He regards with paternal interest a young man of twenty-four years, who is delighting the assembly with some experiments designed to illustrate the "*great reduction of temperature in steam of high elasticity when suddenly expanded.*" Very attractive is the young man as he stands there, tall and slender, his intellectual and unusually handsome face flushed with enthusiasm.

He ends his lecture by boldy thrusting his hand into a jet of steam issuing from the stop cock of a copper boiler before him, to exhibit the curious paradox, that, at a prescribed short distance from its escape, steam will not scald provided *it is hot enough*. This was Henry's first communication to the Albany Institute. Were we to seek the same room a year later, on the evening of March 2d, 1825, we would find the young man again delighting the assembly with his experiments—this time on "the production of cold by the rarefaction of air"—producing a veritable snow storm within six feet of a large stove, and in a room at a temperature not less than eighty degrees Fahrenheit; while perhaps outside on that March night, Nature was producing the same phenomenon on a large scale.[2]



THE ALBANY ACADEMY.

It was through Henry's great facility and pleasure in experimental illustration that he entered the field of science. In 1826 he was appointed Professor of Mathematics and Natural History in the Albany Academy. We have seen him exercising his ingenuity in devising experiments to illustrate his lectures before the Albany Institute; it was in connection with like efforts to exhibit strikingly to his pupils in classes the principles of electro-magnetism, that he made his first contribution to a science which, if we count from Oersted's experiments as its beginning, was at this time six years old. Not much had been done with the subject in America, Henry says, in a paper read before the Albany Institute, Oct. 10, 1827:

---

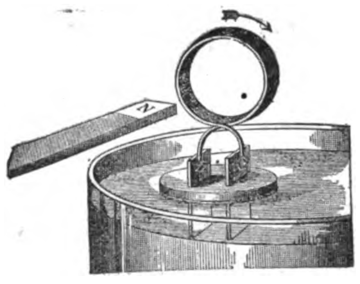
[1] (This society had only recently been established by the union of an oluer one for the "Promotion of Useful Arts in the State of New York," organized Feb., 1791, and the "Albany Lyceum of Natural History," formed and incorporated April 23d, 1825.)

[2] Half a pint of water was poured into a strong copper vessel, of a globular form, and having a capacity of five gallons; a tube of one-fourth of an inch diameter, with a number of holes near the lower end, and a stop-cock attached to the other extremity, was firmly screwed into the neck of the vessel; the lower end of of the tube dipped into the water but a number of holes were above the surface of the liquid, so that a jet of air mingled with with water might be thrown from the fountain. The apparatus was then charged with condensed air, by means of a powerful condensing pump, until the pressure was estimated at nine atmospheres. During the condensation the vessel became sensibly warm. After permitting the apparatus to cool down to the temperature of the room, the stop-cock was opened; the air rushed out with great violence, carrying with it a quantity of water, which was instantly converted into snow. After a few seconds, the tube became filled with ice, which almost entirely stopped the current of air. The neck of the vessel was then partially unscrewed, so as to allow the condensed air to rush out around the screw; in this state the temperature of the whole interior atmosphere was so much reduced as to freeze the remaining water in the vessel."—*Trans. Albany Institute*, Vol. 1, part 2, p. 36.

Although the principle on which this striking result was based was not at this time new, this particular application of it by Henry, thus publically exhibited, was long before any of the numerous patents were obtained for ice-making, not a few of which adopted substantially the same process.

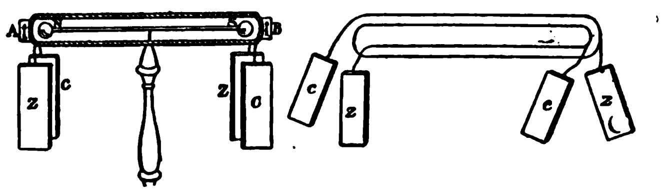
"The subject of electro-magnetism, although one of the most interesting branches of human knowledge, and presenting at the same time the most fruitful field for discovery, is perhaps less generally understood in this country than almost any other department of natural science. Our popular lecturers have not availed themselves of the many interesting and novel experiments with which it can so liberally supply them; and, with a few exceptions, it has not, as yet, been admitted as a part of the course of physical studies pursued in our higher institutions of learning. A principle cause of this inattention to a subject offering so much to instruct and amuse is the difficulty and expense which formerly attended the experiments—a large galvanic battery with instruments of very delicate workmanship being thought indispensible." Sturgeon had helped to obviate this difficulty. He had greatly improved lecture room apparatus for illustrating the electromagnetic reactions of rotation, etc. (where a permanent magnet is employed), by introducing stronger magnets and had thereby succeeded in exhibiting the phenomena on a larger scale and with less battery power. He was for this awarded the silver medal of the Society for the Encouragement of Arts. Henry, after repeating all the experiments of Oersted, Ampere and others, was, from his own experimental investigations, enabled to exhibit to his classes all the illustrations of Sturgeon on a much larger scale; with weak magnets, if necessary, and with still less battery power. These striking results were obtained by a simple expedient. Look again at Schweigger's multiplier. [See figure] Henry recognized the principle involved, viz., that in coiling the wire of a galvanic circuit the strength of the electrical current is increased, and in every case where a single wire circuit had been employed, he used a manifold coil of wire. By means of this coil Schweigger's multiplier became in Henry's hands an instrument of much greater delicacy and power; and Henry was not only able to produce with it more striking effects than Sturgeon had produced, but an apparatus capable of exhibiting phenomena of which Sturgeon's instruments were incapable. Henry says in his paper: "Mr. Sturgeon's suite of apparatus, though superior to any other as far as it goes, does not however form a complete set; as indeed it is plain that his principle of strong magnets cannot be introduced into every article required and particularly in those intended to exhibit the action of the earth's magnetism on a galvanic current, or the operation of two conjunctive wires on each other. To form therefore a set of instruments, on a large scale, that will illustrate all the facts belonging to this science, with the least expense of galvanism, evidently requires some additional modification of apparatus and particularly in those cases in which powerful magnets cannot be applied."

Schweigger's Multiplier.



De la Rive's Floating Ring.

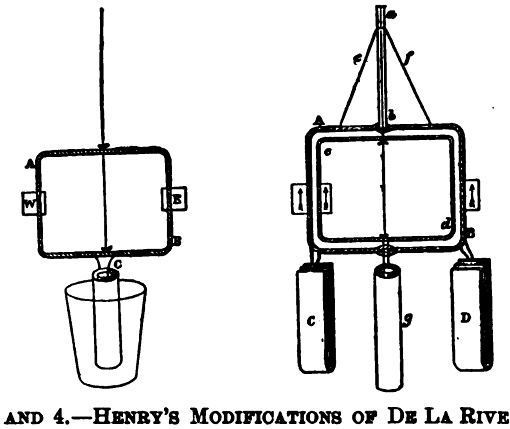
"In a paper published in the Transactions of the Albany Institute, June, 1828, I described some modifications of apparatus intended to supply this deficiency of Mr. Sturgeon by introducing the spiral coil on the principle of the galvanic multiplier of Prof. Schweigger, and this I think is applicable in every case where strong magnets cannot be used. The coil is formed by covering copper wire, from $\frac{1}{40}$ to $\frac{1}{80}$ of an inch in diameter with silk; and in every case which will permit, instead of using a single conducting wire, the effect is multiplied by introducing a coil of this wire closely turned upon itself."



Figs. 1 and 2.—Henry's Modification of Schweigger's Multiplier.

"The following description will render my meaning sufficiently clear:"

"Fig. 1, is an apparatus on the plan of the Multiplier, to show the deflection of a large magnetic needle. It consists of a coil of wire, A B, of an oblong form, about 10 inches in length and one and a half in width, with a small galvanic element attached to each end; the coil is formed of about twenty turns of fine copper or brass wire wound with silk, to prevent contact, and the whole bound together so as to have the appearance of a single wire. The attachment of the zinc and copper is more plainly shown in Fig. 2, which represents a coil of only two turns of the wire; on the left side of the figure the plates are soldered directly to the ends of the wire of the coil; on the right, the plate of zinc *z* is attached to the part of the wire ending with copper on the other side, while the plate of copper on the right corresponds to the zinc on the left. By this arrangement we can instantly reverse the direction of the currents and deflect the needle either to the right or left, by merely holding a tumbler of acidulated water so as to immerse one or the other of the double plates into the fluid. The arrows at A and B, formed of two pieces of card, are intended to show the direction of the currents, and they should point in the course of the wires going from the copper. N S, is the needle, about nine and a half inches long, made by binding together several watch springs, touched separately, so as to form a compound magnet; at the end are two balls of pith, to show the movement of the needle more plainly. This instrument is complete in itself, and we receive the full effect of the instantaneous immersion of the galvanic element."



Figs. 3 and 4.—Henry's Modifications of De La Rive's Ring.

To show the advantage of the coil, take the little instrument called "De la Rive's ring," a modification of Ampere's ingenious and delicate experiment for showing the directive action of the earth as a magnet on a galvanic current when its conductor is free to move. (See representation of it.) C and Z are two plates, one of copper the other of zinc, connected by a loop of copper wire an inch or two in diameter and suspended in a little glass vase, containing acidulated water, which by the aid of a piece of cork D, floats in a vessel of water. The loop of wire is the circuit conveying the electric current C to Z and—free to move—it must, if the magnetism of the earth is produced by electric currents circulating from East to West around it, arrange itself at right angles to the magnetic meridian, and so it does. The effect of this experiment was strikingly enhanced by Henry's method of suspending by a silk thread a large coil thirty inches in length bent into a parallelogram the ends of the wire projecting, and soldered each to a pair of galvanic plates. By placing a tumbler of acidulated water beneath the galvanic plates so that they could dip into it, he caused the coil to assume, after a few oscillations its equatorial position, transverse to the magnetic meridian. We give his own illustration and description of the arrangement.

"Fig. 3 represents a modification of De la Rive's ring on a large scale. A B, is a coil about nine inches by six, with a small cylinder of copper, enclosing another of zinc, without bottoms, soldered to its extremities, which end at C, the whole being suspended by a fibre of raw silk, so as to swing freely in a cup of acidulated water. When this apparatus is made sufficiently light it invariably places itself, after a few oscillations, at right angles to the magnetic meridian. W and E, are two pieces of card, with letters on them, to show which side of the coil will turn to the East or West; they may be properly placed by recollecting that the current from the copper to the zinc has a tendency to circulate in a direction contrary to that of the sun."

By a similar arrangement of two coils of different sizes, the one suspended within the other, Ampere's fine discovery of the mutual action of two electric currents upon each other was as strikingly displayed. See Henry's figure and description of it, as follows:

"Fig. 4 is designed to show the action of two conjunctive wires on each other: A B, is a thick multiplying coil, with galvanic plates attached, in the same manner as shown in Fig. 2; *c d*, is a lighter coil with a double cylinder, precisely similar to Fig. 3, and suspended within the other by a fibre of silk, passing through a glass tube *a*, the end of which is inserted into an opening *b*, in the upper side of A B; *e f* are two wires supporting the glass tube. When the cylinder *g* and the plates C are placed in vessels of acidulated water, the inner coil will immediately arrange itself so that the currents in both coils will circulate the same way; if the vessel be removed from C, and D placed in the fluid, the coil *c d* will turn half way round and again settle, with the currents flowing in the same direction."

"With many other instruments of a similar character, Henry made visible to his classes the newly discovered principles of electro-magnetism, and it is safe to say that in simplicity, distinctness and efficacy such apparatus for the lecture room was far superior to any of the kind then existing. Should anyone be disposed to conclude that this simple extension of Schweigger's multiple coil was unimportant and unmeritorious, the ready answer comes that talented and skillful electricians, laboring to attain the result, had for six years failed to make such an extension. Nor was the result by any means antecedently assured by Schweigger's success with the galvanometer. If Sturgeon's improvement of economizing the battery size and consumption by increasing the magnet factor (in those few cases where available) was well deserving of reward, surely Henry's improvement of a far greater economy by increasing the circuit factor (entirely neglected by Sturgeon) deserved a still higher applause." (Taylor Memorial of Joseph Henry, pp. 215–216.)

THE LIMITATIONS TO LONG DISTANCE TELEPHONY.—III.

BY

H. W. Dunbar

We have now reached the third stated cause of the limitation to telephony and arrived at that cause which the engineer has always considered the vital one, that is, the absolute amount of decay in the amplitude of the vibration, caused by the capacity of the line, and increasing rapidly with the distance from the origin.

Again examining equation (4) we see that the effect of the capacity is first to increase the absolute value of the current at or near the origin, and, second, to cause a logarithmic decrement of its value with an increase in distance from the origin. The self-induction of the circuit causes first a decrease in the absolute value of the current at or near the origin, and, second, decreases the rate of decay caused by the capacity. Thus these two factors work in opposition and some relation must exist between them which will render I a maximum at the distant end.

Taking the first differential coefficient of I with respect to L, equating to zero and solving for L, will give us a value of L which on examination will be found to render I a maximum for any given set of conditions; that is, a definite length of line with a definite resistance, capacity and number of alternations.

$$I = -\frac{2\,E\,\sqrt{C\alpha}\quad e^{\frac{pl}{2}}}{\sqrt[4]{R^2 + L^2\,\omega^2}\,(e^{pl}-1)} \text{ is a maximum when}$$

$$\frac{e^{\frac{pl}{2}}}{\sqrt[4]{R^2 + L^2\,\omega^2}\,(e^{pl}-1)} \text{ is a maximum.}$$

The term $(e^{pl}-1)$ becomes $(e^{pl}+1)$ when $l = \frac{1}{2}\,x_\lambda$, or an odd multiple of $\frac{1}{2}\,x_\lambda$ as previously stated. Therefore its mean value (e^{pl}) may be assumed with no error. (In all cases where the line is of considerable length the exponent pl becomes greater than unity and therefore the difference between $(e^{pl}-1)$ and $(e^{pl}+1)$ is slight.)

$$\frac{e^{\frac{pl}{2}}}{\sqrt[4]{R^2 + L^2\,\omega^2}\,(e^{pl})} \text{ is a maximum when } \sqrt[4]{R^2+L^2\,\omega^2}\,.\,e^{\frac{pl}{2}}$$

or $\frac{1}{4}\,log.\,(R^2 + L^2\,\omega^2) + \frac{pl}{2}$ is a minimum.

Differentiating with respect to L we have

$$\frac{L\,\omega^2}{2\,(R^2 + L^2\,\omega^2)} = \frac{l}{2}.\left(\frac{\omega\,p}{2\,\sqrt{R^2 + L^2\,\omega^2}}\right);$$

$$\text{or } \left\{ (R^2 + L^2\,\omega^2)^{\frac{1}{2}} - L\,\omega \right\}\,(R^2 + L^2\,\omega^2) = \frac{8\,L^2\,\omega^2}{C\,\omega\,l^2}.$$

The term $\left\{ (R^2 + L^2\,\omega^2) - L\,\omega \right\}$ has a maximum value of R and a minimum of 0 as L varies from 0 to infinity.

Designating it by R_o we have

$$R^2 = L^2\,\omega^2\left[\frac{8}{C\,\omega\,l^2\,R_o} - 1\right];$$

$$\text{or } L\,\omega = \frac{R}{\left[\frac{8}{C\,\omega\,l^2\,R_o} - 1\right]^{\frac{1}{2}}} \qquad (9).$$

This equation shows us that if $L\,\omega$ has a finite value the term $\frac{8}{C\,\omega\,l^2\,R_o}$ must exceed unity. Substituting the constants of the Chicago line we have

$$\frac{8}{C\,\omega\,l^2\,R_o} = \frac{8}{\frac{.017}{10^6} \times 1{,}000 \times 4 \times 10^6\,R_o} = \frac{2}{17\,R_o} \text{ at a fre-}$$

quency of 160 periods per second. Hence R_o cannot exceed $\frac{2}{17}$ or 0.118.

But $R_o = (\sqrt{R^2 + L^2\omega^2} - L\omega)$; hence $(R^2 + L^2\omega^2) < (L\omega + 0.118)^2$ or $L\omega > 20.4$. Hence L must exceed 0.0204 henrys per mile.

From the formula (9) we see that $L\omega$ varies from ∞ to 2.2 as R_o decreases in value from 0.118 to 0.059. Therefore the value $L\omega = 20.4$ is accurate enough for all purposes. A single approximation, however, determines its value far closer than 1 per cent. at 20.5. Therefore we see that for this particular rate of alternation the current at the distant end could be increased by an increase in the retardation factor. The abruptness of the curve at its maximum point may be shown by a simple calculation for this frequency, *i. e.*, 160 periods per second.

Value of L in henrys.	Current in amperes (maximum) at the distant end.
.010	$-2E \times .000307$
.020	$-2E \times .000323$
.040	$-2E \times .000314$

Thus the apex of the curve is extremely blunt and the value of the retardation factor may vary throughout a wide range with but little effect upon the resulting current at the distant end even at this low frequency.

An approximation of equation (9) may be written thus:

$R_o = \frac{8}{C\omega l^2}$; but $R_o = \sqrt{R^2 + L^2\omega^2} - L\omega$; hence

$$L\omega = \frac{C\omega l^2 R^2}{16} - \frac{4}{C\omega l^2}. \qquad (10).$$

Where $\frac{C\omega l^2}{16}$ is greater than 2 or 3, little error is introduced by neglecting $\frac{4}{C\omega l^2}$, and we may finally write the approximation

$$L = \frac{C l^2 R^2}{16}. \qquad (11).$$

We see from this that upon such a line as that under discussion, the retardation factor varies directly with the capacity per unit of length, with the square of the resistance per unit of length, and with the square of the length of the circuit. The interesting fact is that it is independent of the rate of alternation. Up to a certain point the factor L is influenced by the rate, increasing with an increase in the frequency as seen by equation (10). But when the rate approaches 100 or more alternations per second upon a line of this length its influence upon the value of L for a maximum I disappears. As all important telephonic rates exceed 100 vibrations per second, the value of L which renders 160 periods per second a maximum will render them all a maximum.

An interesting point is the determination of the length of line upon which the maximum current is naturally reached; that is the length corresponding to a value of L of .00161 henry per mile.

Substituting in (11) we have,

$$l^2 = \frac{16 \times .00161 \times 10^6}{.017 \times 4.84} = 320{,}000.$$

Therefore, $l = 570$ miles, or a distance of 285 miles. Thus with the line construction assumed, no gain in volume could be obtained by an increase in the retardation upon circuits extending to a distance less than 285 miles.

Before proceeding further it would be pertinent to inquire if there exists a finite value of C which would tend to produce a maximum value of the current at the distant end.

$I = -\frac{2E\sqrt{C\omega}}{\sqrt[4]{R^2 + L^2\omega^2}} \; \frac{e^{\frac{pl}{2}}}{e^{pl} - 1}$, which is a maximum when $\sqrt{C\omega}\,\frac{e^{\frac{pl}{2}}}{e^{pl} - 1}$ is a maximum. Remembering that the fraction $\frac{e^{\frac{pl}{2}}}{e^{pl} - 1}$ may be represented by $\frac{1}{e^{\frac{pl}{2}}}$ we will discuss $\frac{\sqrt{C\omega}}{e^{\frac{pl}{2}}}$ for a maximum, or $\left(\frac{1}{2} \log C\omega - \frac{pl}{2}\right)$ for a maximum.

Differentiating and equating to zero, we have

$$\frac{1}{2C} = \frac{l}{2} R_o^{\frac{1}{2}} \frac{\omega}{4\sqrt{\frac{C\omega}{2}}}; \text{ or } C = \frac{8}{l^2 R_o \omega} \qquad (12).$$

Where R_o as before, represents $\sqrt{R^2 + L^2\omega^2} - L\omega$.

Thus we see that under certain conditions the value of the current at the distant end of the line is actually increased by the capacity of the circuit. The value of C to give a maximum current at the distant end varies inversely with the square of the length of circuit and as some power of L and ω determined by the resistance in the factor $(\sqrt{R^2 + L^2\omega^2} - L\omega)$. As an increase in L decreases R_o, C varies directly with some power of L.

It must be borne in mind that this and the other formulæ apply only to cases in which the wave length is not greater than twice the length of the circuit. Thus from equation (12) it would appear possible to secure a greater current at the distant end of a line devoid of all retardation if it contained a small amount of capacity rather than no capacity at all. For when $L = 0$, $R_o = R$ and $C = \frac{8}{l^2 R\omega} = \frac{.0009}{10^6}$. But on substituting these values in (7) we find $x_\lambda = 6{,}800$ miles which is more than twice the circuit length. As C varies inversely with the square of the length and inversely with ω in formula (12) when $L = 0$, and as the wave length varies inversely as the square root of C and ω when $L = 0$, we see that no values of l and ω can render (12) applicable when $L = 0$. This can only mean that when $L = 0$, C must be zero to render I a maximum.

Substituting the constants of the Chicago line in (12) we find that if C had a value of $\frac{8}{4 \times 10^6 \times 1.1 \times 10^3} = \frac{.0018}{10^6}$ instead of $\frac{.017}{10^6}$ it would increase the current at the distant end and render it a maximum for this value of L.

SALADIN'S ELECTRIC FURNACE.

A PAPER has been read by Mons. Saladin, before the Chemical Society of Paris, on his improved electrical furnace. This furnace appears to differ in principle from others, as it is based upon the electrical cautery. A platinum spiral rendered incandescent by means of a continuous or alternating current of electricity is placed in a vessel of refractory material, and the whole is enclosed in a cast-steel case. It is possible to act upon substances placed in this furnace by means of high pressure, as well as high temperature. A side opening in the case communicates with a pump and manometer, and admits of the pressure being increased to 1,000 atmospheres. The range of temperature available is 1,500°–1,800° C., and this is measured by a platinum-rhodium couple, arranged according to Le Chatelier. Mons. Saladin claims that by means of this furnace it becomes possible to fuse metals under high pressure, and while maintaining any desired pressure to cool the molten metal as slowly as is deemed desirable, this cooling being governed by regulating the current. At present we understand that this furnace is being used in obtaining experimentally the reproduction of minerals from elementary matters, the idea being to imitate the probable conditions under which they have been naturally formed.

THE WESTINGHOUSE COMPANY AND THE NIAGARA CONTRACT.

WE print elsewhere in this issue an important communication from Mr. L. B. Stillwell, on behalf of the Westinghouse Co., which sheds a strong side light on the information embodied in Prof. Forbes' paper on the electrical features of the Niagara transmission plant. This communication, taken in connection with Prof. Forbes' own statements, would make it appear that so far as essential features are concerned, the promoters of the Niagara scheme deemed it wise to accept the advice of experienced constructors in preference to that of their consulting electrical engineer. And this brings us back to the old question of the relation between these two frequently antagonistic elements. The consulting electrical engineer's services have from the very outset been little availed of in this country, purchasers of electrical plants having in the large majority of cases left matters entirely in the hands of the contracting companies, which practice has, it must be admitted, given rise to but few conflicts. In the case of the work at Niagara, it would appear that the consulting electrical engineer, instead of confining himself to laying down the conditions and leaving to the contractors to devise the best methods of carrying out the specifications, actually entered into competition with them, with the result that might have been foreseen. According to Mr. Stillwell it would also seem that while the engineers of the Westinghouse Co., are in accord with Prof. Forbes on the selection of the methods adopted, they differ from him radically in the assumptions and reasoning which led them to advocate the final plans adopted.

It would be interesting to know the details of these differences and it is to be hoped that the electrical profession will not be kept in ignorance of them. For this reason it is perhaps a pity that Prof. Forbes' paper could not have been read and discussed on this side of the water also. Probably an early opportunity may be afforded by the Institute for such a timely discussion.

THE TESLA ELECTRICAL OSCILLATOR.

WHILE Mr. Tesla has until the last year or two confined himself to purely electrical work, his most recent labors have been devoted to the solution of a mechanical problem intimately connected with the generation of electric currents, the outcome being his electrical oscillators, of which we describe two additional types in this week's issue. Aside from the numerous possibilities in other fields it would seem that if the "oscillator" fulfills the expectations of its inventor, it is destined to create little short of a revolution in our present methods of power generation and distribution. It must be confessed that in spite of the numerous obvious cases in which the application of motors to the driving of machines and line shafting would prove a gain over the present methods, and despite even the successful working of such plants, the conservative factory owner and machinist still looks with a doubtful glance at these innovations of the last ten years. But, if, as Mr. Tesla claims, he will be able to furnish electric current by means of his oscillator, at anything like one half the cost for fuel now required and with much simpler apparatus, the aspect becomes quite a different one. Such an accomplishment would immediately appeal to every power user and would at once determine the direction of future methods of local power transmission. Indeed it might not be inapt to inquire here also into the probable effect of such an achievement on long distance electrical transmission. With the potentials which have been practically handled up to date, the size of conductors required has not permitted of the extension of power transmission plants utilizing water power, to the distances hoped for, although we note small but constant gains in this respect. With the initial source of energy in the shape of fuel reduced to one half the present cost, it would indeed require an exceptional set of conditions such for example, as those existing at Niagara or in regions far remote from fuel supply to make the utilization of water-powers worth considering for any considerable distance from the fall. Already the cost of water power even locally distributed has in numerous conspicuous instances proved less economical in competition with modern steam engines and a still further improvement in the latter added to the benefits to be derived from electric motors must still further tend to decrease the comparative margin of economy with water power. It seems strange indeed that a power available on the spot should not be able to compete in economy with another form of energy hauled frequently for a distance of hundreds of miles, but experience bears out the conclusions just stated. While the above remarks refer merely to power distribution they are equally applicable to the question of electric lighting and current distribution in general. From Mr. Tesla's observations before the recent meeting of the New York Electrical Society (see THE ELECTRICAL ENGINEER, Dec. 6 and 13, 1893) we infer that he has so far gone into the study of the methods he advocates that we shall not have to wait long for their practical realization.

ELECTRICITY AND THE STATE.

The reference to electricity in no less than three of the annual State papers of New York serves to indicate the important position assumed by this later source of energy. In the reports made to the Legislature by Gov. Flower, State Engineer Schenck and Superintendent of Public Works Hannan, reference is made to the contemplated employment of electricity as a motive power on the Erie Canal. The utterances of Mr. Schenck show him to be still somewhat skeptical as to the economy of the electric method as compared with the steam canal boat, the independence of which still appears to him as a most valuable feature. Judging from his other remarks it is evident that he has never heard of the dynamotor or motor transformer, nor of the work now actually being done by alternate current motors. On the other hand we are glad to note the intelligent grasp of the subject apparent in the brief reference to it contained in Mr. Hannan's report. This gentleman estimates that with a steam electric plant serving a stretch of 50 miles and operating 210 days in the year canal boats can be propelled for 10 cents per mile per boat, while still others estimate it at nearly one half this figure. If during the season when the canal is closed the power could be utilized in other ways the cost would be still further reduced. Mr. Hannan concludes from all this that the claims to consideration for electric motive power on the canal are extremely well founded.

In the message of Governor Flower we note also a reference to the alleged increase of fires due to defective electric wiring, and a suggestion that persons installing such work be licensed by a competent board certifying to their fitness to carry it out properly. There is much to be commended in this plan which was for some time in operation in New England, but has unfortunately been allowed to lapse. Perhaps the trades unions themselves might find the easiest solution of this problem by allowing no one into their ranks who could not pass a rigid examination on wiring work. The statement that in the city of New York there are four times the number of fires that there are in the principal cities of Europe, accompanied by four times the destruction of property, may be true, but to cite it in the present connection without further qualification and without giving any figures or details whatever seems hardly fair. We know as a matter of fact that the actual figures on fires claimed to be of electrical origin do not in the least warrant any such assertion or inference and we are sorry indeed to see so unguarded a statement in a Governor's annual message. Last week we referred to a case within our personal knowledge where the insurance rate had been advanced nearly five fold—from 15 cents per $100 to 70. Inquiry elicits the fact that apartment buildings over a certain height have been re-rated on that basis. As we said last week, electricity has nothing to do with the case.

BI-METALLIC WIRES IN TELEPHONY.

EVER and anon the electrical public is brought face to face with statements and facts so at variance with past experience that they force themselves upon its attention and cause it to pause and ponder. The most recent example of a surprise of this nature is the discovery of the extraordinary properties of a composite wire for the transmission of telephonic currents and indeed for alternating currents in general. If we are to believe the statements printed on another page, from Mr. Wm. H. Eckert, whose long telegraphic and telephonic experience entitles his opinion to some weight, a composite wire embodies within itself properties which serve to overcome retardation whether due to electro-magnetic impedance or electro-static charge while at the same time it makes current largely independent of insulation. A result differing so widely from what we have been accustomed to deem as an inevitable accompaniments of all conductors will of course be accepted with great caution, but as the inventor bases his statements on actual experiments we must await further developments on this decidely interesting innovation with no small hopefulness.

An Injunction Against a "Gas" Lamp.

As we go to press, news reaches us by telegraph that Judge Shipman has to-day (Saturday) granted an injunction against the "Novak" incandescent lamp. The proceedings at Hartford were recently reported in our columns. As we are still without the text of the decision, we are unable to pronounce on its scope. The lamp, it will be remembered, has a bromine atmosphere in the chamber. This was held by the defendants to exclude it from the scope of the Edison patent.

BI-METALLIC WIRES FOR TELEPHONE CONDUCTORS.

OUR readers may recall the fact that early in 1883, the Postal Telegraph Co. in extending its lines to the West employed a composite wire consisting of a steel core upon which a thick layer of copper was deposited. This conductor had a tensile strength greatly exceeding that of any similar line theretofore employed, and, in addition, had a much greater conductivity, its resistance between Chicago and New York being only 1,552 ohms, or a little over 1½ ohms per mile. The results obtained with this wire telegraphically were so good that it at once suggested the possibility of employing the line for telephonic transmission as well, and among those who tried experiments on it were Van Rysselberghe, Baxter and others. Although only a single circuit grounded at both ends was employed, the articulation was distinct with all kinds of transmitters, and between New York and Cleveland the ordinary Bell magneto receiver used as a transmitter was sufficient to carry on conversation. These good results were attributed generally to the high conductivity and excellent insulation of the wire, and subsequent long distance telephone work was carried out on the basis of securing similar advantageous conditions.

Among those who had an opportunity of witnessing these experiments was Mr. Wm. H. Eckert, at that time general manager of the Metropolitan Telegraph and Telephone Co., of New York. When the Long Distance lines between New York and Philadelphia were erected, the difficulty at first experienced in obtaining distinct articulation, before the proper transposition of the wires was effected, impressed itself strongly upon Mr. Eckert, in whose mind the experiments with the Postal Telegraph wire were still fresh. After much thought devoted to the subject Mr. Eckert arrived at the conclusion that neither the greater conductivity nor the higher insulation of the Postal wire accounted for the excellent results obtained with it but that its properties were due to the dual nature of its composition. Subsequent experiments appear to have fully convinced him of the correctness of this view, and in a patent just issued to him we find a number of most interesting statements relating to his discovery.

Mr. Eckert holds that telephonic transmission, or rapidly alternating currents in general, may be more perfectly effected upon a bimetallic conductor, such as steel and copper in equal parts, than upon a conductor of one material such as copper; and with the advantage that such transmission may be effected upon a circuit consisting of a single composite wire and an earth return as perfectly as though two copper wires, each of equal conductivity, were arranged in a closed metallic circuit. In other words, he finds that a single bimetallic conductor joining two distant points is a more perfect medium for telephonic transmission and for conveying generally rapidly alternating currents than are two copper conductors, each of a resistance equal to that of the bimetallic wire; and that from this fact the two conductors necessary to form a single metallic circuit may be replaced by a single wire costing little, if any, more than one-half of a copper metallic circuit. He also claims that less insulation is needed to protect a bimetallic wire than is necessary for copper or other single substance conductors, in the transmission of rapidly alternating currents, and that from this fact not only the expense of constructing cables, whether ærial, underground or submarine, may be greatly reduced but more wires may be placed within a cable than could be done if the usual thickness of insulation were used. Moreover, for the transmission of alternating currents, wires of smaller conductivity according to the ordinary resistance measurements, may be used than is possible if they were constructed of copper, iron or other single metal.

Among the experiments made by Mr. Eckert to demonstrate the practical nature of his discovery is one in which a composite bare wire of No. 20 B. & S. gauge was stretched on the ground for a distance of 10 miles and grounded at both ends. The articulation left nothing to be desired.

Mr. Eckert does not vouchsafe any theory to account for the remarkable properties which he attributes to the composite wire, but contents himself thus far with the statement of the facts as he has found them to exist.

ELECTRIC TRANSPORTATION DEPARTMENT.

GOVERNOR FLOWER ON ELECTRICAL CANAL PROPULSION.

IN his annual message to the New York State Legislature, Governor Flower makes the following reference to the use of electricity on the Erie Canal as one of the means of deriving more benefit from that great waterway:

"The most practical suggestions are contained in plans for increasing the tonnage of the Erie Canal. One of these plans has been in process of construction during the last seven years. It consists in lengthening the locks so as to permit two boats to pass through at the same time, thereby saving expense and time of transportation. Under this policy all but four of the locks which it is feasible to lengthen, in the opinion of the Superintendent of Public Works, have been so lengthenened. The cost has been about $3,000,000 thus far. The results have been disappointing, for the tonnage of the canals has diminished instead of increased. The lengthening of the remaining four locks will not change the situation materially, for it requires on the average about three minutes to lock a boat, so that the time saved between Buffalo and Albany by lengthening the remaining locks would be less than half an hour.

"Another plan proposed in connection with the lengthening of the locks is the deepening of the canal and the raising of its banks, so as to enable boats of larger capacity to be used. The deepening of the canal would necessitate the rebuilding of all its structures —an enormously expensive undertaking; the raising of the banks, however, would be quite feasible as a means of securing greater depth of water. Something in this direction should undoubtely be done when the present capacity of the canal proves insufficient, and at present provision should be made for the prompt removal of all accumulations in the bottom of the canal, so that its full depth may be enjoyed.

"It has seemed to me, however, that the most practical plan for immediately increasing the tonnage of the Erie Canal is that which would supply a speedier and more economical motive power. Mules and horses now propel canal-boats at a rate of about two miles an hour, while steam sends them along at the rate of about three miles. The banks of the canal will stand a speed of about four miles an hour. It seems to me, after personal observation of present methods, that electricity might be applied as a motive power with a considerable saving in cost and a considerable increase in speed. Experiments in this direction were authorized by the last Legislature upon my recommendation, and seem to have demonstrated clearly the feasibility of using electricity as a motive power on the canals, The only question still to be determined is that of cost, and the estimates are quite favorable to a considerable reduction from the cost of propulsion by steam. Just how much of a reduction could be obtained it is of course impossible to say definitely, but very conservative estimates make the saving in cost of transportation at least 25 per cent., and the increase in speed at least 30 per cent. The advantage of electricity over mule or horse power would be much greater. If these results could be attained the benefit to the canal would be immediately greater than the benefit which would flow from all the proposed enlargements, and need not cost the state a penny. Boatmen could make many more trips in a season, fewer employés would be needed on each boat, no money would be required for horses and mules, the large space occupied by steam-boiler and engine would be saved for freight, and danger from fire or explosion would be avoided. At the same time the increased tonnage and business of the canal would provide more employment and more remunerative occupation for boatmen. Other advantages readily suggest themselves. It should be clearly understood, moreover, that the adoption of electricity as a motive power does not mean the abandonment of horse, mule, or steam power if boat-owners prefer to have their boats propelled by these powers. The idea is that whether the state furnishes the electric power from its own plant, or whether individuals or corporations furnish it under contract, there will be no compulsion to use it, but the endeavor will be to supply it at such a low cost to boatmen that they will find it advantageous to apply it to their boats in the interest of economy.

"This plan need not interfere, either, with any proper enlargement or deepening of the canal. Instead, if the plan is found to operate satisfactorily, the next logical and necessary step would probably be to so improve the canal as to enable the use of larger boats. But for the present I am quite convinced that the proper course is to give electric propulsion a fair trial, and if it accomplishes what is claimed for it, a new era of activity and prosperity should begin for our canals. Grain has been carried during the last season from Chicago to Buffalo for as low as one cent a bushel; boatmen can carry it profitably at two cents a bushel. If by cheaper and quicker propulsion the cost from Buffalo to New York by way of the Erie Canal can be reduced to three cents a bushel, as is reasonable to suppose, there is no other carrying route that can successfully compete with it, and a continuance of New York's supremacy is assured. Moreover, the harnessing of the tremendous water torrent of Niagara to the wheels of industry will furnish the cities of Buffalo and Rochester and all western New York with the cheapest power for manufacturing in the United States. We may look forward to the time when the great flour mills of the world will be located there, for the cheapness of power would more than compensate for the cost of transportation of grain from the fields of the Northwest. So with other manufactories. Then, more than ever, will be needed cheap transportation through the State. To-day the Erie Canal does not carry one-half its capacity. Reduce the cost of transportation and increase the speed and the tonnage will increase, and when the tonnage increases then will be the proper time to seriously consider expensive schemes of enlargement.

"The essential point in arranging for the application of electric propulsion on the canals is that the power should be furnished at the lowest possible cost, and any construction of state works for this purpose or any contract with individuals or corporations for supplying power to the boatmen should be hedged about with abundant safeguards for the protection of the public interests."

THE NEW YORK STATE ENGINEER ON CANAL TROLLEYS.

STATE ENGINEER SCHENCK, in his annual report to the New York State Legislature has a very interesting discussion of the application of electricity to the canals of the State. It is as follows:

Of the several schemes of improvement advocated by the friends of the Erie Canal, one of the most feasible, when its comparatively small cost is taken into consideration, is that known as the Seymour plan, by which it is proposed to deepen the canal to a depth of nine feet of water, by raising the banks one foot and by excavating the bottom one foot, except through locks and over aqueducts and culverts, and lengthening the locks so as to permit the passage of double headers.

I have plans for an enlarged canal, 100 feet in width and 12 feet deep, capable of bearing barges 250 feet in length and 25 feet broad on beam, with 10 feet draught of water, and of the lowest possible height above water, so that the greater part of the bridges crossing it could be fixed structures, instead of movable ones. The cost should not exceed $25,000,000.

I recommend that a commission be appointed, whose duty it shall be to examine into this matter and to report its conclusions to the Legislature at the earliest time practicable.

While there are some minor difficulties to be overcome in the application of the trolley system to canal navigation, such as the holding of the boat while not in motion or moving at a low rate of speed and exposed to the action of high winds, in proper position to secure easy contact of the trolley with the wire carrying the current, the devising of means by which boats traveling in the same direction at different rates can pass each other, or by which boats can be brought up to or taken away from a dock, etc., I think none of these difficulties are so serious but that they will be surmounted by the inventive genius of our people. The main question is a purely economic one, and the success or failure of investigations now in progress will be decided by the answer to the question, Can the electric power be furnished to each propeller at less cost than that of steam?

Two trolley methods have been suggested by which to reach the desired end—one by establishing power houses along the line of the canal at such distances apart as may be found economical or desirable, and in these power houses, by the use of fuel to to generate steam, transform this steam power into electric power, transmit this electric power by wire between these power houses, and by means of a trolley wire communicate it to motors in canal boats acting to turn a screw wheel. The other is the generating of electricity in large quantities by means of water power at some point or points where nature has provided the means, and then transmitting the current over long distances by wire.

From the figures furnished by the Albany Electric Railway, I conclude that if, as was shown me, we succeeded in developing in an engine cylinder one horse power per hour with two pounds of coal, we would have a consumption of coal to obtain one horse power per hour applied at a distance of eight miles from power house of from four and a half to four and three-quarters pounds. This is in excess of the amount of the coal consumed by canal steamers, to say nothing of difference in first cost of plant required.

The method of generating electricity in large quantities at points where large water powers exist and thence transmitting it by wire over long distances is the one which, to my mind, contains the greatest promise of success. In order, however, to economically transmit the large quantities required, the current in the feed wire must pass at very high voltage, and in order to secure safety that in the trolley wire must pass at a low voltage. While it is perfectly feasible to transform an alternating current from a high to a low and from a low to a high voltage, unfortunately no means have yet been found for thus dealing with a continuous current, and it is the continuous current alone that has as yet been successfully applied to the operation of motors.

Upon the solution of one or the other of these difficulties, and upon the devising of means to more economically and perfectly insulate the feed wires, depends, in my opinion, the success or failure of the efforts now being made in this direction.

I am advised that there has been developed by a corporation operating at Niagara Falls a water power yielding on the American side 200,000 horse power per hour (*sic*), and on the Canadian side 120,000 horse power per hour, which, they state, could be disposed of at a profit to the corporation at the price of $4 horse power per annum, measured on wires at Niagara Falls, if sold in its entirety. In considering this question it must be remembered that the steamboat has and must continue to hold an advantage over a trolley-propelled electrical boat in that she is independent of outside aid in navigating the Hudson River.

I commend this subject to your careful consideration and hope that you will adopt the necessary legislation to secure the continuance of the investigations and experiments necessary to reach a conclusion.

FROM NEW YORK TO PHILADELPHIA BY ELECTRIC RAILWAY.

WHAT will be, when completed, the longest electric railway in existence is about to be built between New York and Philadelphia by way of Newark, Paterson and Trenton. The originator of the enterprise is Mr. Joseph H. Reall, of Bloomfield, N. J., who is well known as a railway builder, and the New Jersey Railway Company has been formed to carry out his plan.

There is already an electric railway projected along the banks of the Delaware from Philadelphia to Trenton. Beginning where this ceases, Mr. Reall's system leaves the latter town and passes through Lawrenceville, Princeton, Kingston, Rocky Hill and East Millstone to Bound Brook, whence branches lead to Somerville and Raritan on the west and New Brunswick on the east. Passing north from Bound Brook the line runs northeast to Westfield, passing through Dunellen, Plainfield and Fanwood. From Westfield a branch will run to Rahway, Elizabeth, Woodbridge, Boynton Beach and Perth Amboy, forming a short line from North Jersey and Eastern Pennsylvania to the seashore.

The line continues northeast from Westfield passing through Springfield, Millburn, Wyoming, South Orange, Orange, West Orange, East Orange, Bloomfield, Montclair, and thence to Paterson, with a branch from Millburn to Irvington and Newark on the east and to Morristown on the west. Another branch extends from Montclair to Caldwell. Altogether, the system comprises more than one hundred miles of track. From Newark to Jersey City there is now a well equipped electric road in actual operation.

The entire line has been surveyed, the right of way has been secured and the necessary franchises are assured. The people from one end of the line to the other are highly in favor of its construction, and the leading and most influential men in the different towns and the intermediate country through which the road passes are actively interested in and warm supporters of the enterprise. The road will be laid with seventy and ninety pound steel rails and equipped with thirty-four foot, double motor cars of thirty horse power each. The speed will be eight to ten miles per hour in cities and towns, and twenty-five to thirty miles in the country. The cars will be run on from fifteen minutes to one hour headway, according to the amount of traffic, and where the trade demands it, five minutes headway. Five power plants of 1,000 horse power each, located at Trenton, Rocky Hill, Bound Brook, Westfield and Orange will supply the power.

The road will connect with the principal steam roads of the State. It will intersect both the Pennsylvania and Reading at Trenton, the Pennsylvania at New Brunswick, the Lehigh Valley, Reading and New Jersey Central at Bound Brook, the New Jersey Central at Plainfied and Westfield, the Morris & Essex at Millburn, South Orange, Orange and Montclair, the Delaware, Lackawanna & Western at Paterson, the New York & Greenwood Lake at Orange and Montclair, the Erie and the Susquehanna & Western at Paterson.

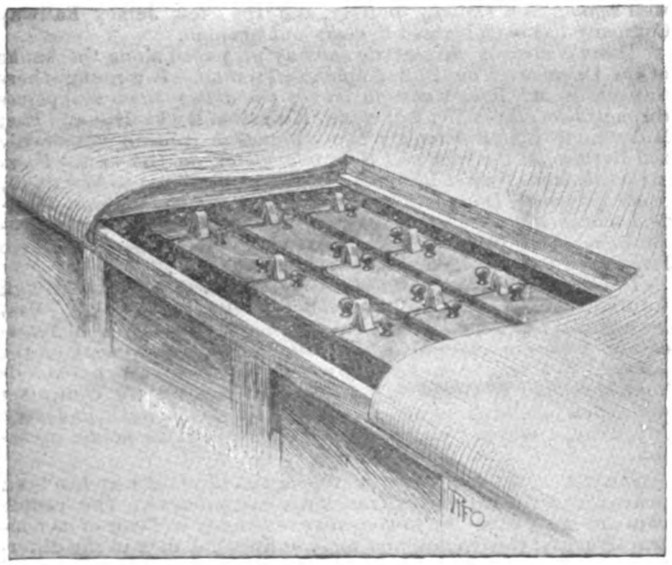
The New Jersey Improvement Company has been incorporated to build and equip the north end of the road ready for operation and work will be commenced early in the spring. Its officers are: J. L. Stadelman, president; E. W. Hine, vice-president; Charles E. W. Smith, treasurer; John U. Bethell, secretary. Another construction company will probably be organized by Mr. Reall to build the southern end and the branch lines.

STORAGE BATTERY TRACTION AT BEREA, OHIO.

The beautiful little town of Berea is located west of Cleveland, O., with which it is connected, besides the railroads, by the Cleveland and Berea Street Railway. This road is ten miles long, and runs through a fertile farming country its entire length, for it connects at the Cleveland end with the terminus of the Woodland Avenue and West Side Street Railway. Starting from the Cleveland end the car has to mount one 4 per cent. grade 600 feet long; then after half a mile stretch of nearly level road comes a grade a little over 5 per cent. about 800 feet long. These two grades are the only large ones on the line but the road is made up of smaller ones as it is in no place level. The track is laid on one side of the country road and follows the ups and downs of the land, as very little grading has been done. The road crosses the L. S. & M. S. R. R. twice and runs under the C. C. C. & St. L. R. R. by a tunnel.

The road is operated by the storage battery system of the Ford-Washburn Storelectro Co., of Cleveland, Ohio. At present there is but one car on the road and this is equipped with only one set of storage batteries; yet this car has been making three round trips, or sixty miles, every day since October 2, and in the first 31 days carried 4,753 passengers and covered about 2,000 miles. Part of the time an open trail car has been attached to the battery car and on Sunday, October 22 the two cars carried 460 passengers on the three round trips; 142 passengers at one time, one way, on the two cars.

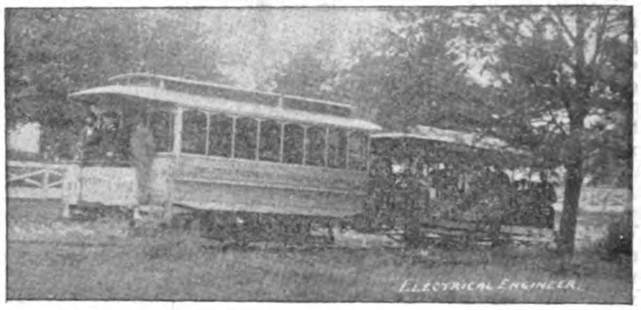
On November 19, the motor car without the trailer brought 78 passengers from Berea to Cleveland. In drawing the trailer and carrying 142 passengers up the 5 per cent. grade the ampere meter registered 130 amperes. A large permanent power house will be erected at the Berea end, which will be equipped with modern machinery for handling and charging the cars and batteries. At present there is a temporary power house, with a 10 h. p. threshing engine and boiler, belted direct to a 16 ampere 500 volt Ford-Washburn generator. The car has only one set of batteries at present, and the cells are charged before each round trip which takes about two hours.



Ford-Washburn Cells Under the Car Seat.

The car is 28 feet long over all and 21 feet inside measure, and was built by the J. G. Brill Co., of Philadelphia, especially for this road. It is painted white with gold trimmings, has plate glass windows, fancy hard wood interior finish and is handsomely upholstered. The batteries are placed under the seats, in three rows of 28 cells each, on either side, making 168 cells in all. The car body is mounted on a Tripp truck with extension springs having a wheel base of 7 feet with 33-inch wheels. The car is propelled by one 35 h. p, series wound Ford-Washburn street car motor weighing 2,000 lbs.

The Ford-Washburn Storelectro Co. have two means of varying the speed of their cars, the first dependent on the manner of coupling the batteries by which three speeds are obtained, *i. e.*, with four sets of 42 cells each in multiple, giving 84 volts, with two sets of 84 cells in multiple giving 168 volts, or with the entire 168 cells in series giving 336 volts; the second consists in commutating the fields by which four changes in speed can be obtained.



The Ford-Washburn Storage Car on the Cleveland and Berea Road.

A special switch for instantaneously shutting off the current is placed at each end of the car to be used in cases of emergency. The car is further equipped with ratchet brakes and all latest improvements.

The road has been in operation since October 2. It has carried over 7,000 passengers, and has plowed its way from Berea to Cleveland through snow which at places was more than two feet deep.

MISCELLANEOUS.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.—IV.

(*Concluded.*)

BY PROF. GEORGE FORBES.

GENERAL DESCRIPTION OF A 5,000 H. P. ALTERNATOR.

On the bed-plate a vertical cylinder is bolted, with projections to support the fixed armature and the bearings of the revolving part. The armature coils are wound independently and can be removed and changed. They are fixed in slots in the fixed armature. They are encased in an oil-tight casing through which oil can be circulated. The field magnet is external to the armature, and has the poles pointing radially inwards. It consists preferably of forged steel supported by a spider with eight arms, which may be of steel with a covering of thin sheet metal, on which cups are provided for forcing air into the interior of the machine. The pole-pieces are bolted on to the steel rim. The field coils are of copper strip, two coils being wound upon each pole, with a space between them for air circulation. The exciting current is applied by rings of tempered copper on the spider, having fixed brushes rubbing on them. The hub of the spider is firmly fixed to the upper end of the shaft. The spider supports the heavy rim by 16 studs and nuts. The shaft is supported by two bearings, each of which has four radial arms, which are bolted to four corresponding projections on the cast-iron cylinder. This cast-iron cylinder is bolted to the bed-plate, and adjusted thereon by wedges. Besides having on it the projections for carrying the bearings on its inner side, it has on its outer periphery a series of vertical ribs against which the stampings, or sheets of iron forming the armature, rest. It also supports the lower end plate on which the armature is built up, and the armature is keyed to it, by a single key. The armature is wound drum fashion—that is, all on the outside. This enables the coils to be wound independently and laid in their place, and also to be easily replaced in case of accident. In order to do this satisfactorily, the slots for each coil in the iron are cut, not radially, but parallel to each other. Each coil is encased in insulating material, which forms a tube through which oil may flow as in a transformer, but may be forced, in which case its circulation is maintained by a pump. Round the base of the machine there are two oil pipes, one being the inlet the other the outlet. The inlet pipe is connected with a reservoir of oil in the power-house. The outlet pipe leads by another pipe to cooling arrangements in running water, from which the oil is pumped to the reservoir. From the inlet pipe 16 brass tubes are led to the junction boxes at the bottom of the 16 coils; the 16 other brass tubes are led from the junction boxes at the top of the coils through the interior of the fixed armature and bent over the foundation plate, and so connected to the outlet pipe which surrounds the bed-plate. The bed-plate is a single iron casting, and in order to enable it to be transported over the railways it was necessary to limit its diameter, as shown in a supplementary drawing, which shows the improved oiling arrangements, which were worked out by my chief draughtsman at Niagara Falls, Mr. Baumann. The armature is built up of thin sheet iron, with ventilating spaces as shown on the drawing. The bolts which hold the armature together are eight in number, to be made of nickel-steel, a metal which has the great advantage of being non-magnetic, and of very high electrical resistance and great mechanical strength. The amount of nickel is 25 per cent.

There are 16 armature coils, eight being of one kind, called "short" coils, and eight of another kind, called "long" coils, the length of wire on each coil being the same. The short coils are bent over at the end plate, and the long coils are wound in one plane, and enclose the short coils. I find that if we are to have a very stiff field, with first-class quality of iron in the fields, each coil would consist of 72 turns of pure copper wire, No. 0 of the Brown & Sharpe gauge, which gives a very low density of current, and reduces the heating. In fact, it has been my view that in designing the machines for so great and permanent a work every effort should be made to reduce the rise in temperature, even to far below what has ever been done in the past. The unequal expansions and contractions of materials in a machine of this kind are very injurious to its permanence, and affect the insulating material seriously. The layers of wire in the coils are separated by mica. Each coil when wound has strips of insulating material laid spirally round it, so that oil may circulate freely in the intervals, and the whole is enclosed in a casing of strong insulating material. The material which I prefer for this purpose is certainly woodite, an eighth of an inch of which will not break down with 30,000 volts, and which is not acted upon by oil even at high temperatures. I have a record of tests with oil which are conclusive on this point. It is quite the best material I have seen for the purpose, though costly, and, being a secret process, it may be difficult to ensure uniformity.

The frames of the bearings are of cast iron, with four radial arms, which rest upon four projections cast on the vertical cylinder, and are bolted to them. By this means, when the field magnets with the shaft have been lifted out of place, the bearings can be twisted through an angle of 45 degrees in a horizontal plane and then raised out of place, leaving a space of five feet in diameter through which portions of the turbine shaft can be raised for repair. The bearings are oiled at the centre by oil forced under pressure through a pipe. The oil is then distributed over the bearings by spiral grooves. A spiral groove is also cut in the hub of the frame, with a pipe at each end to admit of water circulation to cool the bushing. At two opposite sides of each bearing the bushing is made thin, and a rod of bismuth is soldered thereto; so that if the bushing is heated, a thermo-electric current shall be created which, by means of a relay, can ring a bell in the power-house. When this occurs, water can be immediately admitted to cool the bearings, and the attention of the workmen drawn to the necessity of an examination.

One of the parts which required most consideration was the material of which the spider supporting the field magnets should be constructed. The best plan is to make it of steel, for the sake of lightness, and to cover it with a copper covering, which might, I think be spun; or, perhaps better, electro-deposited nickel might be used.

Between the pole-pieces the space is filled up with a screen or plate of metal so as to direct the air ventilation only upon the parts which most require cooling.

It will be obvious from this design, considering that the speed of revolution is 250 per minute, that great care has to be devoted to the balancing of the revolving parts; everything has to be calculated not only for a speed of 250 revolutions, but for double that amount, which is the maximum speed at which the turbines could possibly run—at which speed they might run through a break down of the governor, although this is an accident almost impossible to occur. Each of the revolving parts will of course be balanced individually, and I have suggested a plan for the final balancing which seems likely to be effective. A temporary bushing would be put in the bearings, of india-rubber lined by a thin metal tube. The dynamo would then be rotated slowly and the balance adjusted in the usual way. The speed of revolution would be gradually increased—a new adjustment being made at each speed—until a speed of 500 revolutions a minute is attained, and when an adjustment has been made at this speed it is pretty sure that the balance at 250 revolutions per minute will be very perfect, and the mechanical friction reduced to a minimum.

As stated before, the oiling arrangements have been introduced not only to ensure higher insulation and to preserve the insulating material, but also to lower the temperature as much as possible, because every step we take in the reduction of temperature is an advance. These oiling arrangements may perhaps be adopted in the future, but at present we are not making use of them in the machines which are in process of construction. When we have had experience with these we may in future adopt the oiling arrangements; and as there is likely to be a great development in the direction of electric transmission of power in connection with the utilization of water power in many parts of the world, it has seemed well to me to put before you these details, so that they may be considered in other cases that may arise.

At a meeting of the Board of Directors in New York lately it was resolved, on the recommendation of the consulting engineers of the Company, that the contract for two or three alternators, each of 5,000 h. p., should be assigned to the Westinghouse Electric and Manufacturing Company of Pittsburgh. I would wish to state how much we owe to Mr. Westinghouse, and to his chief engineer, Mr. Schmid, for the zeal with which they have taken this matter up and their desire to meet our views and to secure for us machines of which they felt they could guarantee the satisfactory performance.

Before leaving the subject of the dynamo, I would wish to point out that it has been designed for special circumstances in connection with the Cataract Construction Company's work. If a dynamo of the same type were being constructed for another place, it is certain that modifications would have to be introduced. I particularly draw attention to the fact that some trouble in getting out a good mechanical design arose from the necessity which existed of being able to provide a clear space of about 5 ft. diameter in the middle of the machine without taking the whole machine to pieces, the object of this being to enable us to lift up portions of the turbine shaft which it might be required to put into repair. In any case, where the long shaft existing in our case is not required, the design of the dynamo is much simplified and would more nearly approximate to the first design but arranged for 33 periods a second.

If the present paper were intended to relate solely to the subject of the utilization of power at Niagara Falls I would be content with describing what has actually been done; but I foresee that there is going to be a great development in utilization of water power and its electrical transmission. I am, therefore, inclined to say a few words on some other details which we have been carefully considering, but about which no definite decision has been arrived at.

Before doing this I would direct your attention to the drawing[1] representing a plan of our power house, in which you will perceive the inlet passages A, from the great canal, B, which draws its supply of water from the upper river. From these inlet passages the iron pipes or flumes, C, pass vertically downwards to the bottom of the great wheel-pit, which is a slot cut in the ground to a depth of nearly 200 ft., at present large enough to contain four turbines in line, but which can be extended to a much greater length, the whole capacity of our tunnel being 100,000 h. p. The drawing shows circles, D, in the plan, which indicate the position of the turbine and dynamo above it, and the position of a hatchway F, by which material can be raised or lowered. It will be noticed that between the inlet channels and the wheel-pit the flumes are bent downwards, and thus leave a V-shaped space G, which I have appropriated to make a subway, running along the whole length of the power-house, to carry the high-pressure conductors. It will, of course, be understood that the slot forming the wheel-pit is arched over at the top to form the floor of the power-house, upon which the dynamos rest. It will be noticed that at the north end of the power-house there is a large square chamber, H, in which I propose that all the measuring instruments and other apparatus under the control of the chief electrician shall be assembled. Underneath this chamber there is a cellar in direct communication, first, with the subway which I have described as existing in the power-house; and, second, with the subway which leads outwards from the power-house at present as far as the Pittsburgh Reduction Company's works, and may possibly eventually lead to Buffalo. In this cellar all the high-pressure wires, the transformers, the artificial load, and other high pressure machinery will be placed. It will be noticed that other spaces are left in the floor forming trenches along which the conductors can be carried With these arrangements there can be no possibility of danger to any person in the power-house; and if any wires are to be found laid along the walls of the power-house or elsewhere, I wish it to be a maxim that we shall be able to place upon these wires a card marked "No Danger," so that there will be no possibility of danger from any person touching anything in the power-house.

With regard to the exciting current, the best plan available at this moment is to use one of the machines which are generally known as the Schuckert machines, for converting the alternating into a continuous current, transformers being inserted in order to lower the pressure. In order that the exciting current may increase with the load, it would be well to make these transformers of special construction, each having two primaries and one secondary. One of the primary coils would be in series with the main circuit, and the other in shunt. I would furthermore make these transformers sufficiently large to deal with all the dynamos which are in the central station, and I would subdivide the secondary coil into sections, to enable us to cut out a section of the transformer when we cut out one of the dynamos. When we wish to cut out a dynamo, a switch would be worked which would at the same time short-circuit the field coils of that dynamo and also cut one section of the secondary of the transformer which is supplying exciting current to all the dynamos. This plan allows the fields of all the alternators to be put in series—a desirable arrangement for parallel working. A resistance may, of course, be put in circuit with the fields of the alternators for regulation.

---

[1] The drawings accompanying Prof. Forbes' paper are not yet available for publication.—Eds. E. E.

I presume it will be taken for granted that in any large work of this sort the primary circuit should never be broken when in action. For my part, I hold that this should be the case even in smaller stations.

An important feature for putting the dynamos in parallel, and for removing a dynamo, is an artifical load. It is desirable that this artificial load should consist partly of a resistance and partly of self-induction. It is only by this means that the dynamo which is going to be put in circuit can be brought to exactly the same condition as those which are working, both as regards volts and amperes. It may be well to describe the operation which take place when a dynamo is switched in parallel with the others. First, connection is made between the armature and the artificial load; then the exciting switch is turned so that an extra section of the transformer is put into play, and the short-circuit on the field coils of the dynamo is broken. The dynamo being excited, the turbine is then started, or this may be done at first. The artificial load is then adjusted until the dynamo is giving the same volts and amperes as the others. A synchronizer is then placed between the artificial load and the external circuit, and so soon as the synchronism is attained a switch is closed which connects the artificial load with the external circuit. Resistance is then put into the artificial load until there is very little current going through it, when it is switched out, and the dynamos are all working in parallel. To cut out a dynamo from the circuit the operations are performed in the opposite order. The artificial load with high resistance is put in connection with the external circuit; the resistance is gradually diminished until it indicates the amount of work that is being performed by one dynamo; the connection between the artificial load and the main circuit is then broken, leaving the dynamo (which is being switched out) feeding the artificial load. The resistance of the latter may then be increased, and the exciting switch actuated so as to short-circuit the fields of the dynamo, and to remove one section from the secondary of the exciting transformer. The supply of water to the turbine may then be shut off.

If machinery is worked, even at 20,000 volts, in the manner I have described, there is no possibility of injury from any great rise of electrical pressure, unless the external circuit be by any means accidentally broken. To provide against this sort of trouble I would have wires coming from the external circuit where it enters the power-house, connected through a large resistance, or through the primary of a transformer, the secondary of which contains a resistance. In circuit with it I would have a break consisting of two carbon points at a distance of about half an inch apart if we were dealing with 20,000 volts, so that an arc could not be formed unless the pressure rose above the normal value. Under these circumstances, so soon as any resonant effect due to the breaking of the circuit or due to any other cause raises the electric pressure above the normal, an arc is established across the carbon points, and so a load is put on which removes the cause of the extra high pressure. This is the only automatic means which I have been hitherto able to think of which is sufficiently rapid in its action to overcome any possibility of injury to the dynamo or transformers.

I have attempted in the course of this Paper to give you some idea of the work which has been actually done or decided upon at Niagara Falls, and also to show you the views to which I have been led by any special experiences which I may have had as to the general ideas which ought to guide us in the construction of plant in the future for transmitting power to a distance electrically.

In describing the different plans which are available I have avoided mentioning the names of those numerous electrical engineers and manufacturers who, by their inventions, researches, or applications have advanced the art; or discussing their claims to priority; but I cannot conclude this Paper without mentioning the names of some of those who, in one way or another, have made great steps in the applications of alternating currents to power purposes. I would particularly mention the names of Messrs. Ganz and Co., Mr. Schuckert, the Allgemeine Electricitâts Gesellschaft (of Berlin), the Oerlikon Fabrik, and Messrs. Brown, Boveri & Co.; also Mr. Eickemeyer, Mr. Ferranti, Prof. Ferraris, Prof. Fleming, Dr. J. Hopkinson, Messrs. Hutin and Leblanc, Mr. Rankin Kennedy, Prof. Mengarini, Mr. Mordey, Mr. Tesla, Prof. Elihu Thomson, and Mr. Henry Wilde. I feel that all of us owe a great deal to their work.

In conclusion, I wish to draw attention to the figures which show the relative merits of high and low frequency with polyphase motors.

Everything is identical in the two figures, except that, the frequency of one (*a*) being double of the other (*b*), *a* has 16 poles, *b* has 8. The armature is identical in both, and revolves at the same speed and does the same work; and the field revolves at the same rate in both, and the induction and current-density are the same. The differences are that *a* has more copper and less iron than *b*. The comparison of efficiency depends on the depth of both. As an example, assume that *a* has 50 per cent. more copper in the fields than *b*, the ampere-turns per pole being necessarily the same in both, and that *b* has 50 per cent. more iron than *a*, and that the hysteresis loss in *b* (= H_b) is equal to the resistance loss in its copper coils (= C_b). The values for *a* are—

$$H_a = 2 \times \frac{2}{3} \times H_b\,;$$

$$C_a = \frac{3}{2} C_b\,;$$

$$H_a + C_a = \left(\frac{4}{3} + \frac{3}{2}\right)\frac{H_b + C_b}{2} = 1.42 \times (H_b + C_b).$$

Thus the total losses in the field of higher frequency (neglecting eddy-currents) are 42 per cent. more than in the field of lower frequency.

LITERATURE.

How to Wire Buildings. By Augustus Noll, E.E. New York, 1893. C. C. Shelley. 162 pages, 5½ x 8 inches. Price $1.50.

IN this utilitarian age when practice keep so closely at the heels of theory the successful workman in any branch must fortify himself in every way if he is not to be outdistanced by his more studious fellows. This demand for more knowledge has given rise to a host of so-called "practical" books intended to convey to the artisan the results of actual experience, as distinguished from the theory or laws on which the subject treated of is based. But there are two kinds of "practical" works. One of these is the result of a gathering together of materials and knowledge acquired by hearsay, as it were, and frequently the outcome of much painstaking labor on the part of the authors. Such works have a certain value, but they almost invariably fall short of their intended purpose by lacking those small but all-important details which serve as the links that join the whole together and the knowledge of which makes the successful workman.

The other type of the "practical" book is that which is written by one who has actually done the things which he describes, who knows in just what manner they are carried out most conveniently and expeditiously and who is thus in a position to note the little, all important details above alluded to. It is of this second type that Mr. Noll's book is an excellent example. Himself a successful workman (in the true sense), of long and varied experience, he is eminently qualified to describe to others what he has himself found to give the best results in practice.

In these days of Boards of Fire Underwriters and numberless wiring rules and constant threats of increased insurance rates on buildings lighted by electricity it is specially desirable to put into the hands of every one connected with the installation of a lighting plant, from the architect down to the wireman, a source of correct information, and the work before us is the first of its kind which can be said to meet broadly the requirements.

The author in carrying out his design first gives us a series of considerations governing wiring work in general, and introduces here the duties and qualifications of a wiring foreman. That all-important question of the location of the conductors serves to bring out forcibly the value in a work of this kind of that personal experience about alluded to. Throughout all this section of the book we read between the lines the instances of the "troubles" encountered in the past, the removal of which has often been accomplished at the cost of much time and money. The way "how not to do" work of this kind is here forcibly brought home to the reader. The location of the conductors, with reference to the other numerous adjuncts to modern buildings, having been discussed, the author takes up the question of the division of circuits and distribution of current, and the laying out of wiring plans, and here again Mr. Noll's ripe experience is manifested. He describes clearly, and by the aid of diagrams, the "panel" or "grouping" system, and various other systems, and the means to be adopted for obtaining equal pressure throughout the system, and pointing out the situations in which one or the other will be found to be most advantageous. The wiring from converters is also fully explained and shown by diagrams.

That later outgrowth of necessity, conduit wiring, has afforded the author opportunity of showing the beauty and value of this system to its fullest extent, and the methods of carrying out such work are treated with corresponding fullness in a well-illustrated chapter.

Not the least important part of work of this nature is the location of the lamp outlets in order to obtain the best illumination. On this subject, that is, the distribution of light, we find much of value, especially to the architect, on whom the duty of selecting the proper location of lamps usually falls. In addition to the general rules found in the past to give the best lighting effects, a number of special cases are added and considered, such as the lighting of show windows, churches, theatres, paintings, etc. We also find a special chapter devoted to stage and theatre wiring which is replete with practical hints and suggestions.

As the work is intended also as a guide and aid to those in charge of isolated lighting plants, the author has included a number of useful chapters on kindred topics, such as insulation, appliances, connections, fuse wire, pulleys, belting, the setting up and running of dynamos and motors, and also on the duties of the engineer in charge.

Throughout the volume we find practical examples of wiring worked out by simple methods which can be followed by any one having a knowledge of simple arithmetic, with accompanying tables of safe carrying capacity, etc.

A feature of the book are the excellent diagrams which might well be used as models by those engaged in laying out wiring plans. If to all this we add a most pleasing literary style of treatment of the subject, Mr. Noll's work will be found to have a charm not often met with in books of such a strictly technical character. We may be pardoned if we make use here of the trite expression, that no one in any way connected with the installation or care of an electric light plant can afford to be without this book.

REPORTS OF COMPANIES.

CHANGES IN GENERAL ELECTRIC OFFICES.

In accordance with the policy of economy and retrenchment that has been carried out for some time past by its executive committee, the General Electric Co. has now decided to move its "main offices" to Schenectady, where the largest works are. As a result of this change, preparations are already being made for the transfer to Schenectady of various departments heretofore located at New York, Boston and Lynn, and every vacant house or room in the old Dutch town is being rapidly taken up. There will thus result a notable concentration of the manufacturing, selling and engineering forces of the company, and it is believed that much expensive delay and friction will be avoided. The departments moved include the Lighting, Power, Mining, Railway, Supply and Accounting, as well as the Engineering. This will necessitate the removal to Schenectady of the Engineering Staff from Lynn, and the heads of all these departments will also have to make the like change. It has been rumored that Prof. Elihu Thomson would move to Schenectady, but this is obviously untrue. A large amount of manufacturing of staple goods will still be done at Lynn, but it is the intention to handle heavier work at Schenectady on account of its superior facilities. The executive offices will remain in Boston as heretofore. The Company will retain offices at 44 Broad st., New York, where the Eastern District will continue its headquarters and the executive officers and heads of departments will use them as necessity or convenience of business requires.

These changes will naturally have some effect on the District Offices, into which the policy of retrenchment is also being pushed; but it will be a few months before all the necessary readjustments will be clearly seen or made. The Eastern District, will, as stated, continue in New York, but important changes or reductions have been begun in Washington and Pittsburgh. Western business will, it is understood, be almost wholly handled from Chicago.

COLLEGE NOTES.

THE ROBERTS CORRESPONDENCE SCHOOL OF TECHNOLOGY.

Mr. E. P. Roberts has added to the faculty of his Correspondence School, Brainard Block, Cleveland, Mr. George T. Hanchett, a graduate of the Boston Institute of Technology, and a man of considerable practical experience. Mr. Hanchett learned the trade of machinist, and worked his way through college, a fact that will give peculiar value to his instruction. Local courses in analytical geometry and calculus by Mr. Hanchett, and roof trusses and bridge building by Mr. F. C. Osborne have just started, and the local class in civil engineering begins this month. Mr. Roberts finds that having the local class is of very great assistance in presenting the matter to his correspondence students, as the staff are thereby enabled to anticipate many of the questions that would be asked them. They give a local lecture on the subject, then revise it, paying special attention to the snags on which the local students have struck. The school is now educating men in every section of the country, and has many inquiries from Canada.

LEGAL NOTES.

EDISON PHONOGRAPH LITIGATION.

MR. EDISON VS. THE EDISON UNITED PHONOGRAPH CO.

Suit for $1,000,000 damages has been begun by Thomas A. Edison in the New Jersey Supreme Court against the Edison United Phonograph Company. The alleged damages are represented to have been done the plaintiff through the sales of phonographs in this country and abroad by the defendants.

The Edison United Phonograph Company has also begun a suit against Thomas A. Edison, the Edison Phonograph Company and the North American Phonograph Company for $400,000 damages claimed to have been done the plaintiff's business by the defendant companies in selling phonographs in foreign countries.

PERSONAL.

Prof. I. Thornton Osmond who has for some years been developing a course of electrical engineering in the Department of Physics in the Pennsylvania State College, has succeeded in getting the trustees to make a separate electrical engineering department. He will now devote himself again strictly to scientific work in physics. Prof. Osmond has favored The Electrical Engineer with many interesting contributions.

Mr. Newton Hall, who for some time past has been connected with one of our most esteemed electrical contemporaries, has resigned his position, and is now interested in the American Electrical Publishing Co., with headquarters at 136 Liberty street. He is the assistant manager of this new concern, and in that capacity will have charge of the publications which it will issue, notably the *Electrical and Street Railway Reporter*, a journal to make its first appearance March 1 as a monthly. Combined with this journal will be July and January issues called Directory Editions, whose character is described in their title. Mr. Hall has long made a specialty of this class of work, in which his past success, accuracy and experience will now prove of great value. If Mr. Hall gives us a really good Electrical Directory all will be forgiven.

OBITUARY.

A. C. WHITE.

The death of Mr. A. C. White, who was well known in telephone circles, took place on the 27th of December at his home in Boston. Mr. White was born in North Dighton, Mass., in 1858. He had been associated with telephone interests for the past seven years. A graduate of the Massachusetts Institute of Technology in 1882, where he completed the regularly prescribed course in physics, he at once entered the electrical field, in which he was to become so active a worker. His studies at the Institute of Technology were entered upon with a distinct leaning towards electrical matter, and the marked ability shown by him in his work was later testified to by his appointment as lecturer at the Institute on some of the commercial aspects of electric lighting.

His first position on graduting was with the U. S. Electric Lighting Company in Boston. While there he did some work on the arc light which led to an ingenious experimental method of regulation depending on the sudden change in the E. M. F. of the arc in passing from the hissing to the silent condition. The results of this work were published at the time in an English electrical periodical. His association with the U. S. Company terminated in 1884. At that time he went West, and was until 1888 connected with the Western Edison Company in Chicago. It was during his association with these two active companies, at a time when electric lighting was making great progress in being introduced in this country and when problems to be solved cropped up in rapid succession, that Mr. White obtained the great fund of experience and practical knowledge of all the details of the electrical business for which he was so well and favorably known by those in the fraternity who came into contact with him.

In 1886 he entered the employ of the American Bell Telephone Company in Boston. The principal result of his labors in this field was the invention of the present Long Distance Transmitter—known to telephone men as the "Solid Back Transmitter"—which has contributed in a remarkable degree to the development of the long distance service.

Mr. White was a member of the American Institute of Electrical Engineers, the Society of Arts, and the Mathematical Physical Society. A wife and young daughter survive him.

SOCIETY AND CLUB NOTES.

UNIVERSITY EXTENSION LECTURES TO ELECTRICAL WORKERS.

THE excellent educational work that is now being done by means of what is known as University Extension lectures and studies furnishes remarkable evidence of the general public desire for fuller information and instruction on the subjects that cannot well be taught at school and yet are ordinarily beyond the reach of those who are unable to attend a college course. In England, where it originated, the plan of University Extension may be said to have risen to the dignity of a "national movement," so widely and successfully has it been applied; while in this country admirable results have already been attained on similar lines. New York State has given generous support to the idea, and in this city Columbia College has taken the work in hand with the vigor and the enthusiasm that are so rich with promise for her splendid future.

Under the auspices of Columbia College, the organization known as the Brotherhood of Inside Electrical Workers has formed a University Extension Club, whose membership is already running up to 500. In this club each member subscribes $2 for a course of ten lectures on practical electrical subjects, but the lectures will also be thrown open to anyone who is willing to spend 25 cents each time for the privilege of listening to any special one or two. Toward this praiseworthy scheme, so entirely creditable to a trade organization, President Low has himself contributed $1,000, while the various firms in the Electrical Contractors' Association have also given substantial financial proof of their support of the movement. In this way the expenses will be met, including those of the hire of the large hall at Cooper Union, the use of apparatus and current, and the use of lantern and other auxiliaries. The course of lectures arranged is as follows:

Jan. 15.—Batteries, Primary, Secondary and Thermo. Mr. C. O. Mailloux.

Jan. 22.—Alternating Current Dynamos, Motors and Transformers. Mr. Wm. Stanley, Jr.

Jan. 29.—Direct Current Dynamos and Motors. Dr. Schuyler S. Wheeler.

Feb. 5.—Electrical Measurements. Mr. A. E. Kennelly.

Feb. 12.—Electric Lighting. Prof. F. B. Crocker.

Feb 19.—Street Railways. Mr. T. C. Martin.

Feb. 26.—Power. Mr. Nikola Tesla.

March 5.—Telegraphs. Mr. Wm. Maver, Jr.

March 12.—Telephones. Mr. J. J. Carty.

March 19.—Alarms. Mr. Wm. Maver Jr.

A very interesting feature is that these lectures, each of which is to be a plain, straightforward explanation of the subject, will be followed by class work. The instructor in charge will give a short talk on the subject of the preceding lecture. This talk, which will be in the nature of a "review," will embody answers to questions that have been submitted to him in writing. This work will be in charge of Mr. W. H. Freedman, tutor in electrical engineering at Columbia College, and will be most valuable to all who participate in it. Members will also be helped by syllabuses and by lists of good books to read in connection with any preferred branch of study.

BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

Before the Electrical Department of the Institute, of which section Mr. James Hamblet is president, on Friday, Jan. 5, Mr. A. W. R. Peirce of the Crocker-Wheeler Electric Co. read a paper on "The Dynamo: Its Construction and the Principles of Operation." The lecture was largely attended, a delegation from the electrical class at the Pratt Institute augmenting the regular numbers. Mr. Peirce handled his subject in a delightful way, illustrating his remarks by blackboard drawings and by parts of dynamos and portions of machines in the process of construction. In the course of his remarks he referred to the Davenport motor which has been thoroughly illustrated and described in THE ELECTRICAL ENGINEER, and which is now in this office as a valued relic.

DR. PUPIN ON "ELECTRICAL RESONANCE" BEFORE THE NEW YORK ELECTRICAL SOCIETY.

THE next meeting of the New York Electrical Society will be held at Columbia College, on Tuesday, Jan. 16, at 8 p. m. Prof. Michael I. Pupin will deliver a lecture on "Electrical Resonance," accompanied by interesting experiments showing the properties and influence of self-induction and capacity on electric circuits.

AUSTIN ENGINEERING CO.

THE officers of the Austin Engineering Co. who represent in Pittsburgh, Pa., the Altoona (Pa.) Mfg. Co., builders of the M. A. Green automatic cut-off engines, have been removed from 514 Lewis Block to 51 Schmidt Building, 95 Fifth Avenue.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED DECEMBER 26, 1893.

Alarms and Signals:—

Electric Bell, A. J. Oehring, Chicago, Ill., 511,451. Filed Apl. 25, 1891.

Fire Alarm Telegraph, C. H. Rudd, Chicago, Ill., 511,462. Filed May 19, 1892.

Employs two electro magnetic helices in different parallel branches of the alarm circuit adapted to act in opposition to each other upon an armature, heat responsive devices adapted to open the circuit, a resistance coil in one of the branches, mechanism controlled by the armature for sending the alarm signal, and a ground branch from the main circuit.

Electric Signaling Apparatus, T. B. Doolittle, Bridgeport, Conn., 511,731. Filed Feb. 13, 1893.

Claim 2 follows:

A visual signal indicator comprising in combination an electro-magnet, a casing and a bodily-moving inductive armature confined in said casing and having its movements limited thereby, the casing being provided within a suitable aperture for the display of the armature.

Conductors, Conduits and Insulators:—

Electric Wire Covering, F. S. Randall, Philadelphia, Pa., 511,547. Filed June 2, 1893.

A covering consisting of raw cotton in bulk.

Insulator, C. N. Hammond, Boston, Mass., 511,611. Filed Sept. 1, 1892.

Insulator, C. N. Hammond, Boston, Mass., 511,612. Filed Apl. 12, 1893.

Galvanic and Thermo-Electric Batteries:—

Galvanic Battery, H. T. Johnson, New York, 511,434. Filed April 21, 1893.

Employs a containing cup forming the positive electrode, a semi-solid filling with the cup, and a negative electrode having an uneven surface and embedded in the filling.

Process of and Composition for the Manufacture of Porous Cups for Electric Batteries, F. G. Curtis, Philadelphia, Pa., 511,514. Filed Feb. 13, 1893.

Distribution:—

Electric Transformer, J. J. Wood, Fort Wayne, Ind., 511,574. Filed May 19, 1893.

Relates especially to the sub-division of the respective laminæ of the envelope of an iron clad transformer.

Dynamos and Motors:—

Governor for Electric Motors, J. Marty, Jr., Cleveland, O., 511,347. Filed Oct. 10, 1892.

Has the commutator bars arranged helically instead of straight and means for shifting the brushes in the direction of the commutator axis.

Method of and Means for Compounding Dynamo Electric Machines, E. Thomson, Swampscott, Mass, 511,375. Filed Nov. 28, 1892.

Claim 1 follows:—

The method of sustaining or increasing the E. M. F. of a dynamo electric machine, which consists in magnetizing pole pieces adjacent to the polarized part of an armature by induction from the armature itself.

Electric Locomotive, J. G. McCormick, Louisville, Ky., 511,448. Filed April 1, 1892.

Has for its principal object to mount the armature independently upon the axle of the car so that the momentum will be delivered directly to the axle and the revolution will be coincident with that of the wheels.

Current Regulator for Dynamo Electric Machines, C. D. Haskins, Brooklyn, N. Y., 511,523. Filed Nov. 12, 1892.

Employs an electro magnetic device for shifting the brushes.

Electrical Transmission of Power, N. Tesla, New York, 511,559. Filed Dec. 8, 1888.

The invention consists in passing alternating current obtained from one original source throught both of the energizing circuits of the motor and retarding the phases of the current in one circuit to a greater or less extent than in the other. See THE ELECTRICAL ENGINEER, Jan. 3, 1894.

System of Electrical Power Transmission, N. Tesla, N. Y., 511,560. Filed Dec. 8, 1888.

Similar in its object to No. 511,559.

Rotary Electro Magnetic Engine, H. P. White, Kalamazoo, Mich., 511,570. Filed Feb. 15, 1893.

Employs a multipolar armature rotated upon its axis by the combined forces of elementary magnetic attraction and repulsion and also by the tendency of a magnetic pole to move past the electrified wire.

Electric Motor Apparatus, W. A. Johnston, A. W. Browne and J. C. Davidson, Prince's Bay, N. Y., 511,621: Filed April 25, 1893.

Relates to application of electric motors to the manipulation of dental apparatus.

Lamps and Appurtenances:—

Electric Arc Lamp, R. Belfield, London, Eng., 511,495. Filed April 5, 1893.

Employs a rocking feeding mechanism carrying a geared sector actuating a toothed wheel, and a pendulum plate embracing the toothed wheel, and engaging it with inwardly extending teeth.

Rosette for Electric Lights, C. N. Hammond, Boston, Mass. 511,613. Filed June 30, 1893.

Has projections on the side serving as binders for the feed wire, and having guides for the lamp cord strands permitting the latter to be connected with the feed wires at the point protected by the flanges.

Fire Guard for Lamp Cords, E. E. Angell, Somerville, Mass., and S. Porter, Boston, Mass., 511,720. Filed April 20, 1893.

Measurement:—

Electric Measuring Instrument, E. Thomson, Swampscott, Mass., 511,376. Filed March 2, 1893.

A combined voltmeter and ammeter arranged to register either volts or amperes by the throwing of a single switch, and provided with a double scale by which its indication may be read in the desired unit.

Electric Meter, L. Brillié, Paris, France, 511,401. Filed Nov. 22, 1893.

A meter in which an electro dynamometer serves to control the speed of a motor exerting an opposing tendency on the dynamometer through the medium of a magnetic retarder.

Electric Measuring Apparatus, T. Bruger, Bockenheim, Germany, 511,503. Filed June 21, 1887.

The invention consists in the combination with a stationary polarized solenoid, of a double solenoid, the succession of the poles of which is positive negative and negative positive, said double solenoid being mounted co-axially to the stationary solenoid and adapted to move over the same.

Miscellaneous:—

Method of Electric Commutation and Fluid Electric Commutator, C. E. Emery, Brooklyn, New York, 511,328. Filed Dec. 28, 1892.

The invention consists of a method of commutation in which the current is conveyed from the conductors to the commutator sections by means of a circulating conducting fluid.

Process of and Apparatus for Manufacturing Ozone Gas, E. Fahrig, Marseilles, Ill., 511,330. Filed June 18, 1892.

Process of Making Resistance Plates. C. E. Carpenter, Bridgeport, Conn., 511,407. Filed Feb. 7, 1893.

Relates to a special insulation of the Carpenter enamel rheostat.

Process for the Manufacture of Paraamidophenol Sulphonic Acid, A. A. Noyes and A. Clement, Boston, Mass., 511,450. Filed Mch. 16, 1893.

Carbonizing Apparatus, I. L. Roberts, Brooklyn, N. Y., 511,459. Filed Dec. 8, 1892.

The process consists of placing the articles to be carbonized in a mass of sand or like non-conducting material and passing a current of electricity through a conductor in contact with the mass.

Safety Device for Electric Circuits, C. H. Rudd, Evanston, Ill., 511,461. Filed Dec. 10, 1888.

Consists of a high resistance shunt around the lamps connected to ground so as to provide a high resistance path for static discharge.

Machine for Separating Magnetic from Non Magnetic Substances, G. G. Crosby, New York. 511,512. Filed Jan. 11, 1893.

Patrol Box, W. Eglin, Philadelphia, Pa., 511,599. Filed Jan. 19, 1892.

Electrolyzing Apparatus, A. J. O. Chalandre, Paris, France, 511,682. Filed Sept. 13, 1893.

Electric Cautery Apparatus, J. A. Wotton and E. A. Bostrom, Atlanta, Ga., 511,742. Filed June 26, 1893.

Electric Grain Weighing Scale, J. and D. De P. A. Outcalt, Spotswood, N. J., 511,647. Filed July 8, 1893.

Railways and Appliances :—

Conduit Railway Trolley, J. C. Love, Chicago, Ill., 511,342. Filed May 17, 1892.

Employs a contact device consisting of a grooved shoe and means for supporting it so as to allow lateral oscillatory movement.

Trolley for Conduit Railways, J. C. Love, Chicago, Ill., 511,343. Filed May 17, 1892.

Relates especially to the contact devices and means for supporting them upon the car.

Support for Electrical Conductors, J. C. Love, Philadelphia, Pa., 511,344. Filed Jan. 21, 1893.

Employs two gripping plates whose jaws engage the conductor and a support comprising a two part socketed clamp, and insulating material surrounding the plates when in the socket of the lamp.

Tension Device for Electric Conductors, J. C. Love, Philadelphia, Pa., 511,345. Filed Jan. 21, 1893.

Has for its object to maintain a constant longitudinal tension upon the trolley wire to avoid sag between its points of support.

Trolley Bar Carrier for Cars, J. C. Love, Philadelphia, Pa., 511,346. Filed Jan. 21, 1893.

Trolley Wire Crossing, H. Geise, Philadelphia, Pa., 511,419. Filed June 26, 1893.

Claim 1 follows:

A crossing device comprising, in combination, conducting wires insulated at the point of intersection and crossing each other at a point above the normal level of the wires, and a travel plate provided below the point of crossing and upon which the trolley wheels of both lines are adapted to travel.

Conduit for Electric Railways, H. D. Oler, Paterson, N. J., 511,452. Filed Aug. 23, 1892.

The invention consists in the combination with a conduit of a conductor held in a longitudinal groove in blocks in the conduit, sliding blocks in said groove and swinging members in the conduit and actuated from a wheel on the car for successively bringing the several blocks in contact with the conductor.

Converter System for Electric Railways, G. E. Hesse, Brooklyn, N. Y., 511,524. Filed Nov. 21, 1892.

Employs a rail having branches wound with insulated wire so that the rail itself may be used as a primary magnet.

Electric Railway Switching Mechanism, C. J. Kintner, New York, 511,627. Filed June 24, 1893.

Relates to sectional conductor systems in conduit railways.

Telephones and Apparatus :—

Telephone, B. Pickering, Dayton, O., 511,858. Filed Jan. 29, 1881.

A combined telephone, microphone and alarm.

Telephonic Instrument, P. Rabbidge, Sydney, New South Wales, 511,456. Filed Apl. 22, 1893.

Employs a spring armature distinct from the diaphragm and enclosed within the receiver case, and a gravity switch cutting out the alarm circuit when the receiver is in use.

Multiple Switchboard System for Telephone Exchanges, C. E. Scribner, Chicago, Ill., 511,464. Filed Apl. 26, 1893.

Telephone System, F. R. Colvin, New York, 511,589. Filed June 26, 1893.

Has for its object to permit telephonic intercommunication between a plurality of stations without a central exchange.

Telephone System, J. J. McNally, California, Mo., 511,739. Filed Aug. 31, 1893.

Has for its object to automatically make connection between one station and another.

THE ENGINEERING MAGAZINE FOR JANUARY.

In the shape of a souvenir of the World's Fair, the *Engineering Magazine* has issued a superb January number, which carries out in a most admirable manner the aim to indicate the practical value of the Fair in stimulating science and industry. It has an illuminated cover, 82 pages of special illustrations, 158 pages of illustrated articles and 124 pages of advertisements, a total of nearly 370 pages of the single issue, the price of which, as usual, is only 25 cents. Mr. J. R. Dunlap, editor and proprietor, deserves hearty felicitations on such a magnificent production, which certainly marks the highest point ever reached in monthly technical journalism. Many of the contributions to the issue are of interest to electrical engineers. There is a contrast between electricity in 1876 and 1893, by Prof. Elihu Thomson; an excellent electrical department, by Mr. F. L. Pope, and a discriminating review of Cox's "Continuous Current Dynamos and Motors," by Mr. Nelson W. Perry.

ELECTRICAL EXECUTION.

A BILL is to be pushed in the Massachusetts Legislature legalizing execution by electricity.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

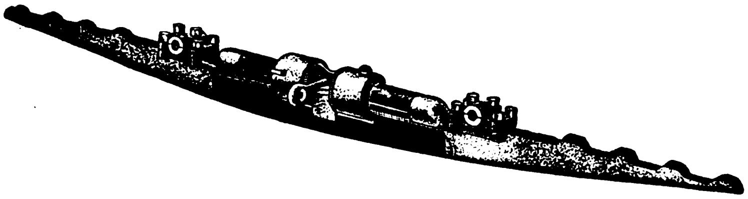
THE "ACME" PORTABLE TESTING SET.

QUEEN & Co., incorporated, Philadelphia, are making a renewed push of their "Acme" portable testing set, which was temporarily withdrawn from the market because of certain small defects which have now been overcome in a thoroughly satisfactory manner. This type succeeds the "T305" form, which met with a large sale, though it was much more bulky and heavier than the present style—besides lacking the essential feature of a battery. The "Acme" set is "multum in parvo" in completeness and compactness, while it can be used under every possible condition as to electrical fields or mechanical vibrations. For testing the resistance of dynamos, motors, lamp filaments, line wire and in fact whenever "ohms" are to be measured, an engineer or expert will find it an apparatus that can be relied upon to work well.

After a careful test the U. S. Government has informed the makers that the set will be accepted for service on ship-board in the Navy, where the requirements are extremely exacting. In addition to this a World's Fair diploma was awarded Queen & Co. for "Testing Sets and Standard Resistances," so that they feel well pleased with the commendation which has been accorded to their resistance measuring apparatus. Circular No. 445 will be mailed upon application.

ÆTNA SECTION INSULATOR.

THE insulator illustrated in the accompanying engraving has been severely tested before placing on the market. It is of simple design, strong and durable. The wooden piece between the terminals is renewable and can be changed while on the line. A convenient clamping device renders it possible to leave enough trolley wire coiled on top of the section insulator, to allow of its being let out to repair the line in case of a break.



ÆTNA SECTION INSULATOR.

Another part of this combination clamp holds the feed wire in such a way as to obviate the necessity of stripping the insulation from the wire, except at the part held by the clamp. By this arrangement the feed wire is left insulated from the poles to the section insulators and between the line where there is a double track.

The insulation is Ætna, and no hood is necessary to protect the insulation. Of the several hundreds already in use none have been provided with hoods and results of this insulator are reported as highly satisfactory. It is manufactured by Albert & J. M. Anderson, of Boston.

WHAT CONSTITUTES A MERRY CHRISTMAS.

THE ELECTRIC APPLIANCE COMPANY of Chicago, have been having a particularly merry Christmas principally on account of the fact that they were able by dint of hard hustling to get their entire trade supplied with copies of their latest edition of catalogue and for the past week have been in receipt of numerous congratulatory letters complimenting its completeness, attractive appearance and intelligent arrangement. It is unnecessary to state that a great many of the letters were accompanied with a substantial proof of appreciation in the shape of large orders for material selected from the new book.

ASSIGNMENT OF THE RAILWAY EQUIPMENT CO.

Mr. W. R. Mason, general manager of the Railway Equipment Co., Chicago, has notified the trade that as a result of the existing depression, it has been found advisable and prudent to make an assignment. Mr. Geo. O. Fairbanks has been appointed assignee. Mr. Mason looks for but a temporary difficulty and asks for a continuance of support.

THE SIMPLEX ELECTRIC CO. has moved its offices from 622 Atlantic avenue, Boston, to 75–81 Cornhill, that city.

UNITED COLUMBIAN ELECTRIC CO.

THE apparatus of the above company for electric railway work, has already been described in our pages. The president of the company, Mr. Hewitt Boice, is pushing its interests in a manner that promises well for its success. Mr. Boice has had a business career that qualifies him admirably to direct such an enterprise. A resident of Kingston, N. Y., he has extensive blue stone quarries on the line of the Ulster & Delaware Railroad, and has been engaged in the stone industry for 20 years. The bulk of the blue stone used in New York City is furnished by him, and from his properties come also the immense blocks of finished stone used for sidewalks on the Astor and Vanderbilt properties. Some time ago, Mr. Boice recognized the ability and ingenuity of Mr. Winkler, in work that has often been referred to in our columns; and he has given the necessary assistance and backing to the efforts which have brought the Winkler "twin motor" to its present successful stage of development. Electricity has always depended much upon such aid and confidence on the part of farsighted and courageous capital, and it is the hope of all that Mr. Boice will find every expectation realized in entering so actively into the already enormous field of electric railway development.

JAS. I. AYER & CO.

THE following notice which will be of great interest to the electric lighting community has just been issued in St. Louis. Mr. Ayer is well known as a central station manager and as a president of the National Electric Light Association:

> We offer our services as Electrical Experts and Consulting Engineers, for the designing of and superintending the complete construction of Electric Lighting Plants of every character; Street Railway Power Plants and electrical construction; adjusting insurance Losses on electrical apparatus; examinations of and reports on the Physical and Financial Condition of electrical properties; estimates and formulating Contracts; electrical plans and specifications for Architects and similar work.
>
> We have to recommend our services for this work Mr. Ayer's experience of more than ten years' in designing, constructing and operating electric plants of different characters, embracing arc and incandescent plants for central stations, power plants for electric work, and isolated plants for buildings, together with his thorough knowledge of the practical requirements in the operation of electrical apparatus and the management of electrical properties.
>
> The plant of the Municipal Electric Lighting and Power Company, of St. Louis, one of the largest in the world, was designed and constructed by him, and operated under his management until its absorption by other lighting interests.
>
> Mr. Ayer is a member of the American Society of Mechanical Engineers, and the American Institute of Electrical Engineers.
>
> Mr. Broughton graduated at Cornell University in 1890 as a Mechanical and Electrical Engineer, and has been engaged for more than three years in practical work in the installation and operation of electrical apparatus of all kinds used for lighting and motor power.
>
> JAS. I. AYER,
> ST. LOUIS, January 1st, 1894. H. P. BROUGHTON.

NEW PRICE LIST OF THE COLUMBIA INCANDESCENT LAMP COMPANY.

THE following advice has reached us from the Columbia Incandescent Lamp Co. of St. Louis:—

We beg to advise you after the 10th day of January, the price of Columbia lamps will be as follows:—

10, 16 and 20 c. p. lamps	$0 32½	net.
25 c. p. "	.35	"
32 c. p. "	.50	"
50 c. p. "	.75	"
Special Railway and Anchored Filament	.37½	"

The above prices are for barrel lots and over. For less quantities than barrel lots 2½ cts. each will be added.

The same high grade of the Columbia lamp will be maintained. We are enabled to make this reduction by reason of the magnificent support which has been given us by users of incandescent lamps throughout the United States during the past year, which has enabled us to largely increase our manufacturing facilities and add additional machinery which has reduced the cost.

THE PETTINGELL-ANDREWS' CALENDAR.

THE PETTINGELL-ANDREWS CO., dealers in electrical supplies at 192–202 Summer street, Boston, have sent each of their friends one of the most attractive advertising calendars that have been issued this year. The calendar proper is of just the right size and is printed in good, heavy, dignified black figures, while on the card is an excellent monochrome representing an ocean steamship bravely battling the waves. A frame for the picture is suggested by an armored cable enclosing one corner, its ends lost in the flying spray, and a piece of Interior conduit at the diagonally opposite corner. The name of the company appears above, surmounted by the ever-present Okonite trade mark, and a heavy coil of "P. A." triple braid line wire floats gaily on the crest of a wave alongside the ship as it is rapidly wafted before the wind, hotly pursued by a flock of gulls who have mistaken it for a dough nut.

EMERSON ELECTRIC MFG. COMPANY.

THE EMERSON ELECTRIC MFG. COMPANY, of St. Louis, is at present engaged in making a number of handsome switchboards according to drawings and specifications received from companies desiring such apparatus. Besides the general business of the Emerson Electric Mfg. Company, this class of work is now becoming a specialty with them, and they will be glad to make estimates upon switchboards under any specifications that may be furnished.

PRICE OF BEACON LAMPS REDUCED.

ALTHOUGH very much improved lately in all essential qualities, the Beacon lamps are now being offered to the public at a reduced price. In lots of 1,000 or over, the 16 c. p. lamp will cost 30 cents; in barrel lots of 200, 32 cents, and in smaller quantities 35 cents. The Beacon Vacuum Pump and Electrical Company, Irvington street, Boston, invite correspondence from manufacturers desirous of making their lamp under a license.

ALUMINUM MANUFACTURE AT NIAGARA.

A DISPATCH of recent date from Lockport, N. Y., says: Negotiations which are practically completed, it is understood, are being made for a compromise of the litigation between the Cowles Electric Smelting and Aluminum Company of Lockport and the Pittsburgh Aluminum Company by a consolidation of the two. In the event of union the entire local plant will go to Niagara Falls, where the Pittsburgh Company is preparing to build a factory which will be the largest electric aluminum smelting concern in the world.

MR. F. R. CHINNOCK.

MR. F. R. CHINNOCK, who for the past two years has been the general eastern agent of the Ball Engine Co., of Erie, Pa., has resigned his agency of that company and will again enter the electrical field, with which industry he was so long identified before taking up the sale of engines.

Mr. Chinnock feels that he will be still more successful in the field of electricity in which line he met with much success as an agent of the Edison General Electric Co., with which his many friends will remember he was associated for eight years.

NEW YORK NOTES.

MR. HARRY W. COLBY formerly with the General Electric Co. and the Mather Electric Co., has opened offices in the Central Building, Liberty street, for the Holtzer-Cabot Electric Co. of Boston. The New York office will handle the Holtzer-Cabot dynamos and motors for the entire country outside of New England.

THE SCHULTZ BELTING CO., of St. Louis, through their New York office at 225 Pearl street, have recently shipped to Yokohama, Japan, as the result of a small order sent out some time ago, two 11" dynamo belts, the aggregate length being 115 feet. They have also furnished new belts for the Central Opera House, New York. In this latter installation one of the chief features is the exclusion of the much-talked-of air cushion, and the fact that the belts can be run very slack, and noiselessly, without deteriorating the strength of the leather.

THE CONSOLIDATED CAR HEATING CO., Albany, N. Y., has received a second order from England for direct steam storage heating equipments. These equipments are so arranged that the temperature in each compartment can be separately regulated. The C., ., C. & St. L., otherwise known as the "Big Four," the Lehigh Valley, the New York, Ontario and Western, the Fall Brook, the Connecticut River and the Boston and Albany Railroads have recently abandoned all other patterns of steam couplers and have made the Sewall coupler their standard. The Consolidated Car Heating Co., Albany, N. Y., has sold over 10,000 Sewall couplers since the beginning of the present heating season.

THE ACCUMULATOR CO., of 224 Chestnut street, Philadelphia, announce that they are now putting on the market their standard accumulators greatly improved in mechanical design and construction. They will be glad to quote prices.

MR. WALTER C. MCKINLOCK, secretary of the Metropolitan Electric Company of Chicago, has just returned from a successful business trip and reports the outlook for his new company as very promising. The company are now handling the Blair adjustable lamp hanger, which enables the lamp to be raised or lowered automatically.

THE PERKINS ELECTRIC SWITCH COMPANY, of Hartford, Conn., have decided to open an office in Boston, and have taken room 71, Hathaway Building, 620 Atlantic Avenue, with Mr. F. B. Smith in charge. Mr. Smith will carry a full line of all the Perkins well-known specialities, and will thus be able to fill all orders promptly from stock.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XVII. JANUARY 17, 1894. No. 298.

THE PRACTICAL ECONOMY OF ELECTRIC HEAT COMPARED WITH THE BLAST FURNACE.

BY

Isaiah L. Roberts

THE art of electric heating has progressed so far that no one now doubts its utility in some few arts such as electric welding and cooking, while even others, more bold, have ventured to apply it to heating rooms and cars. There are still others who dream of the time when electric heat will be about the only heat used for any purpose. The vast majority of people will say that it will be a long time before the blast furnace is displaced by the electric furnace, because so much heat is required in such a case that it can never be generated economically be electricity. I shall endeaver to show here briefly that this dream is not so far off as it appears, and is not only possible but can be made practical at the present time if suitable furnaces are constructed.

At first thought one is inclined to imagine that where low heats are required electricity would be most economical in use, but in fact it is just the reverse. At the present price of electric energy, houses cannot be heated so economically as by steam or water but where any substance or space is to be heated above or near a red heat electric heat can be applied cheaper than any other, regardless of the shape, size or nature of the article to be heated. I have proved the above assertions by the most careful tests, a few of which I will describe here.

Let us take the simplest and easiest case first, namely, the heating of a conductor. I used for this test a platinum wire about five centimetres long and two millimetres thick. A glass alcohol lamp filled with absolute alcohol, wick well saturated and the whole glass capped, was weighed on a pair of good chemical scales. In a thin glass beaker containing 40 c. c. of water a small thermometer reading in fractions of a degree was placed and the whole brought to the temperature of the room.

The room was kept within two degress of a constant temperature by a thermostat connected to a steam coil valve. The alcohol lamp was lighted, the wire held by a pair of pliers at as near one end as possible and held in the flame at the most favorable angle possible to get the most heat. When it showed color from heat it was removed and instantly dropped into the water. The water was stirred with the thermometer until thoroughly mixed, and the rise in temperature noted. This was repeated with different sizes of the flame and at higher and lower temperatures so as to find the most economical point of loss of alcohol, the lamp being instantly extinguished, capped and reweighed to ascertain the loss. The same wire was then clamped between two copper clamps so that as little of the wire touched the clamps as possible. To these were attached a voltmeter, and an ammeter was placed in the circuit of the electric current. The current was switched on and timed until a color was shown in the wire about the same as was shown in the flame, when it was quickly released and dropped into the water. The stirring and reading of the thermometer, as well as the time and reading of the instruments, were all gone through with and repeated at different temperatures up to incandescence of the wire, as well as at very slight heats.

The results were then compared. Figuring the amount of electric energy as against the thermic power of alcohol lost, it was found that in the case of the alcohol, less than one half of one per cent. of the heat generated had got into the wire at a red heat while about ninety per cent., of the electric energy was recovered as heat.

It was thought that while this was fair for the electricity it was not fair to the alcohol. So two wires, each half the weight and about the same length as the original one, were used with better results, while four of one quarter the weight showed still better; but even by such subdivision, which in practice would be very unfair to electricity, there was still shown to be about 30 per cent. margin in favor of the current.

The next set of experiments was conducted in well-made furnaces and under equally favorable conditions, except that in the use of charcoal as the heating agent, the best fuel possible was employed, namely, dry charcoal. A well-jacketed fire-brick lined furnace was used, and a proper charge of coal of selected sizes was placed in the furnace to the best advantage and fired until it was well aglow. Then a piece of a square iron shaft, weighing about one kilogram, and 20 centimetres long, was provided; also a pail of water, thermometer, and large, though accurate and fine-reading, scales. The furnace was placed on the platform and weighed. While burning full of coal, the iron was thrust in the centre of the coal when the furnace was well heated and draught open. When a red color appeared in the iron it was taken out, dropped into the water, and the change in weight of furnace noted; also the rise of temperature of the water was figured against the calorific equivalent of the carbon lost. This was repeated again with two pieces of iron half the weight, and then with four of one quarter the weight, so as to give the coal the best possible chance to act on the iron. I may state here that the proportions of the quantity of metal core to that of the coal was that prescribed by the best blast furnace practice. The large bar was then placed in the jaws of a Thomson welding machine and heated to a red heat and thrown into the same quantity of water at the same initial temperature and the rise noted; this rise was then figured against the electric energy consumed in heating.

Comparative results showed that in the furnace where the single heavy bar of iron was heated, about ¾ of one per cent. of heat generated found its way into the iron, while even when divided up, so as to favor the coal, only about 2 per cent. was recovered; while in the electrically heated piece, about 88 per cent. of the current was recovered as heat. It was found that urging the fire by a blower made the time shorter but greatly decreased the economy of the furnace. In order to get even the results shown, the heat had to literally soak into the iron from the coal and walls of the furnace; while in the case of the current, the iron in a single piece was heated in about two minutes.

The third and last set of tests was made on non-conducting crucibles which were of good Hessian make. The crucibles each contained two kilos of brass scraps and turnings covered by suitable flux and one set in the charcoal furnace and properly fired, the fuel being charcoal of selected sizes and the size of the crucible being that best suited to the size of the furnace. The other crucible of same size and weight was put in a furnace especially made for that purpose and adapted to the work, and the construction of which the writer hopes to give in a subsequent communication.

The charcoal furnace was well fired before the crucible was put in. The crucible and contents were then weighed and placed in the furnace on a bed of live coals and well and quickly packed around with fresh, dry, selected charcoal, which was also weighed. The fire was given the requisite and most economical blowing until the brass was melted, when the crucible was removed and the furnace was weighed and the loss of carbon noted.

The electric furnace was then heated until it was as near the temperature that the charcoal furnace was, so far as could be judged, and then the crucible was set in and the current consumption from that moment noted until the brass was fused, when the last reading was taken.

The result of these tests was that the calculations showed the efficiency for the charcoal furnace to be about $1\frac{1}{2}$ per cent., while the electric furnace had an efficiency of about 85 per cent. It must be here noted that water tests for temperature could not be made, because of the great heat and mass; but the specific heat was calculated from data well known to the physicist.

No claim is made for these tests that they were more than approximately exact, because in the water tests some heat escaped as steam when the red hot metal was thrown in; but the comparison was almost perfect, and that is what was desired more than accuracy.

These tests prove conclusively the claims set forth by the writer in the beginning of this article. The reason for this is not difficult to understand. Heating by combustion, from its nature, must be accompanied by bulky apparatus, as fuels must have an abundance of air for proper combustion. Therefore to utilize this heat to its greatest advantage, large and comparatively cool surfaces must be presented. The steam boiler and gas engine are the best instruments known for this purpose, and thanks to the great engineers of our day they can convert 10 per cent. of the heat of flame into mechanical energy. The electrician can convert 90 per cent. of this, or 9 per cent. of the energy of combustion into electricity and thus 8 to 9 per cent. of the flame heat can be put electrically into the thing heated, whereas with a direct method even in a large blast furnace where the fuel is mixed with the iron, not over 6 per cent. of the fuel is actually utilized to smelt the iron.[1] The application of electric heat to brass and iron foundries, to glass, pottery, and enameling furnaces and especially to the art of baking carbons, can now be practically carried out with great economy in fuel and time, if properly constructed furnaces are used.

From the results of these tests it is perfectly safe to say that from $\frac{1}{2}$ to $\frac{9}{10}$ of the fuel now used for the above purposes can be saved if its heat be first converted into electricity.

PRIVATE TELEPHONES IN AUSTRALIA.

So long as a squatter keeps his telephone on his own property, says the *Melbourne Argus*, he is quite within his rights, but if his wires cross a public road he renders himself amenable to the law, which forbids a private person to erect a telephone or telegraph, the monopoly being reserved for the Government. The Colonial Postmaster-General does not wish to prohibit telephones under such circumstances, and he has, therefore, had regulations prepared, which have been passed by the Governor in Council, charging a license fee of £1 per mile per annum for the first four miles, and after that 10s. per mile; the fee, however, in no case to exceed £7 per annum. The height at which the wire must be carried across roads is specified, and it is also provided that in no case shall a fee be charged or accepted for the use of the line.

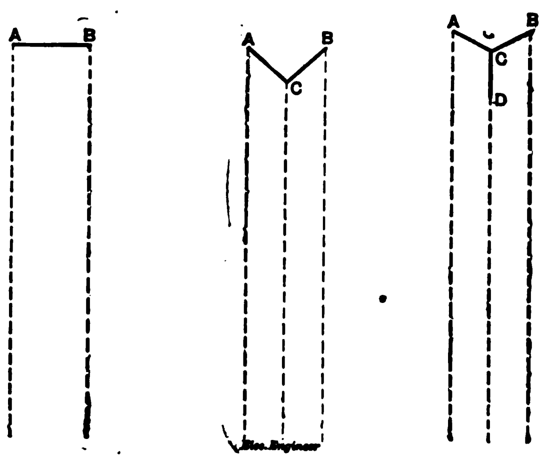
RELATIVE ECONOMY OF COPPER IN SINGLE-PHASE, TWO-PHASE AND THREE-PHASE TRANSMISSION.

BY

W L R Emmet

In the report of Prof. George Forbes' paper on "The Electrical Transmission of Power from Niagara Falls," begun in The Electrical Engineer, of December 20th, the following statement is made:

> **With regard to the relative merits of two and three phases, several claims that cannot be supported have been put forward in favor of the latter. First, it is claimed that the saving in copper on the line is 25 per cent. over a one-phase system, and 25 or 18 per cent. over two-phase system, according as four or three wires are used for the purpose. I investigated this matter carefully, and arrived at the conclusion that this was not the case, and that the three-phase system had no advantage in this respect over a two-phase system with three wires.**



Figs. 1, 2 and 3.

In a paper read before Section "G," of the British Association on September 18 last, Mr. Gisbert Kapp makes the following statement:

> **If we put all the systems on the same footing as regards efficiency and safety of insulation, we find the following, viz: If for the transmission of a certain power over a given distance by continuous current, 100 tons of copper are required for the line, then the single-phase alternating, and the two-phase four-wire system will require 200 tons, the two-phase three-wire system will require 290 tons, and the three-phase three-wire system only 150 tons. As far as the line is concerned, there is thus a distinct advantage in the employment of the three-phase system.**

The facts concerning which these gentlemen disagree are of great importance, since the use of multiphase apparatus is daily increasing, and every user has to decide between the two and three-phase systems, each of which is advocated by one or more of the large electrical companies of the country. That the figures given by Mr. Kapp are correct within the premises he assumes, is easily shown by the process given below.

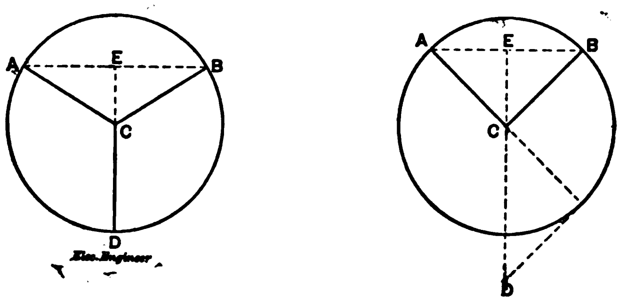
Figs. 1, 2 and 3 represent three circuits arranged, respectively, on single-phase, two-phase three wire, and three-phase systems. The dotted lines represent the line wires which are all assumed to be of equal length. The full lines represent the portions of circuits on which work is done or light furnished. We will assume that the maximum potential difference between any two wires in each of these circuits is the same, and equal to E; also that the energy in watts in the useful part of the circuits in each case is equal to W, and that the energy lost in lines in each case is the same and equal to K. M and N are constants which reduce the quantities which are expressed in maxima to mean values, then apply in the same manner to the corresponding quantities in each case.

---

[1] See a Paper read by Sir Lowthian Bell, Bart., F. R. S., before the Iron and Steel Institute, Darlington, England, Sept., 1893.

In Fig. 1 the current in each of the line wires is $\frac{W M}{E M}$ and the resistance of each of the wires is $\frac{K}{2} + \frac{W^2 N}{E^2 N}$, and the conductivity of each is $\frac{2 W^2}{E^2 K}$. Hence the total conductivity in line wires is $\frac{4 W^2}{E^2 K}$.

In Fig. 2 the maximum potential difference between the points A and B being E, the maximum difference between B and C will be $\frac{E}{\sqrt{2}}$. In Fig. 5, in which A C and B C represent the maximum potential differences between the points A and C, and B and C, Fig. 2; and the angle A C B is equal to the difference of phase of these quantities which in the two-phase system is 90 degrees. Then A B = B C $\sqrt{2}$ will equal the maximum potential difference between A and B, or E, by the simple relation of periodic quantities, the variations being assumed to be sinusoidal. The current in each of the branches A C and A B, Fig. 2, will then be $\frac{W}{2} \times \frac{\sqrt{2}}{E} M = \frac{W M}{E \sqrt{2}}$. These currents flow in the line wires from A and B, and they combine at C to form a current in the line wire from C which will bear the same relation to either of the currents which form it that A C or A B bear to C D, in Fig. 5. These two combining currents are equal and differ in phase by 90 degrees. Hence the current in line wire from C is $\frac{W M}{E M}$. Thus the total current carried on the three wires over the single length of the line is $\frac{W}{E} \times (1 + \sqrt{2})$. The total energy loss in lines being K, the total conductivity of the three wires which carry this current must be $\frac{W^2}{E^2 K} \times 5.83$.



FIGS. 4 AND 5.

In Fig. 3 the three circuits A C, B C and D C carry equal currents, two of these currents which differ in phase by 120 degrees uniting to form a periodic current equal to each of those from which it is formed. If A C and B C, Fig. 4, represent in quantity and phase the currents at A and B, Fig. 3, then C D will represent in quantity and phase the current at D, Fig. 3, and if B C and A C, Fig. 4, represent the corresponding potential differences in Fig. 3, then A B, Fig. 4, represents the maximum potential difference between wires which exists on the system, this being assumed equal to E. The maximum difference between the point C and any of the points A, B or D is $\frac{E}{\sqrt{3}}$. Then, since the total energy is W, the current in each branch is $\frac{W M}{3} \times \frac{\sqrt{3}}{E M} = \frac{W}{E \sqrt{3}}$. The total current carried the single length of the line is $\frac{W}{E} \sqrt{3}$, and since the $C^2 R$ loss in the line is K the total conductivity must be $\frac{W^2}{E^2 K} \times 3$.

Hence the conductivities required are found to be in the proportion of 4, 5.83 and 3. These proportions are the same as between the numbers 200, 291, and 150 which correspond to the copper weights given by Kapp. Since the only limitation of economy in copper in any line is determined by the pressure which can be safely and conveniently generated and handled, it would seem that no rational basis of comparison can be assumed other than that from which these figures are derived; namely, the assumption, that in lines of equal length equal amounts of energy are transmitted, and equal amounts are lost in lines, with equal strain on insulation and danger from shocks.

THE LEWIS ELECTRIC CAR LIGHTING SYSTEM.

AMONG the many details of railway operation the lighting of the cars has occupied the attention of railway managers as much, perhaps, as any other. Although the dangerous character of oil and also of gas, is well recognized, progress in the application of the electric light has been very slow, especially in this country, so that we find but very few trains now equipped with this method of illumination.

In the early experiments in this field, cars were provided with individual sets of batteries charged at terminal stations. It was soon found, however, that the change of batteries required at the end of each trip, and the liability of the charge becoming exhausted before the end of the trip was reached, made this method too uncertain and troublesome. As a result, the plan was adopted of supplying the cars with batteries which are kept constantly charged from a dynamo placed in the baggage car, and driven by a steam engine supplied with steam from the locomotive boiler. Though this plan has worked more satisfactorily than the previous one, it still has its drawbacks in that it drains the boiler directly of steam required for traction purposes and not infrequently on heavy grades the dynamo has to be stopped in order to maintain the speed of the train. Besides that, it makes the installation an expensive one, and the plant occupies valuable room in the baggage car. It was early suggested to drive the dynamo from the car axle, but with the swiveling trucks employed on American railways this method of driving has heretofore introduced difficulties which have until recently rendered it unsuccessful, although with the rigid trucks employed abroad it has met with fair success.

The prime essentials of any such system, subjected to the severe conditions obtaining in railway practice, are simplicity, that is, ease of handling, and economy both of operation and first cost. It was with these objects in view that Lieut. Isaac N. Lewis, U. S. A., some time ago attacked the problem. He has now succeeded in developing a system of car lighting which seems to possess all the elements of a successful commercial apparatus.

The Lewis system which has been experimented with on a car of the New York Central Railroad consists essentially of a dynamo driven from the car axle, supplying current to a set of storage cells which furnish current during the period of stopping of the train, and during other periods, as will be explained presently.

The dynamo is mounted on the truck and consists of a four pole iron-clad machine completely enclosed so as to exclude all dust, and provided with graphite bearing for the armature shaft. The armature is driven directly from the axle by means of spiral spring flexible "belting" which is capable of responding to all the movements of the truck, and thus obviates all necessity for equalizing arrangements such as belt tighteners, idlers, etc., to keep the belt taut.

The dynamo, of 1 k. w. capacity weighs barely 200 pounds and readily finds room on the truck. The current is led into a battery of 11 cells and these feed the 20 volt lamps of which there are 12 to each car.

Being driven directly from the car axle some means must of course be provided first for maintaining the direction of the current supplied to the batteries uniform, and at the same time cutting out the dynamo when its speed falls so low as to bring its E. M. F. below that of the storage batteries on the car. Again the arrangement must be such that the dynamo potential remains practically constant no matter at what speed the car is running. All these necessary requirements have been worked out with great simplicity by Lieut. Lewis. A uniform direction of the current is maintained by a polechanger while the cut-out, operated by a governor on the dynamo shaft, interrupts the current when the speed of the car falls below that required for the charging of the cells. The uniformity of potential at varying speeds is controlled entirely by a particular and simple method of winding of the dynamo, and no auxiliary regulating apparatus of any kind is employed. Throughout a range of current from 0 to 35 amperes, for which the dynamo is designed, the E. M. F. does not differ 1 volt, at all the varying speeds, from the point at which the dynamo is cut in up to the maximum.

The cutting out of the current from the dynamo below a certain speed relieves the locomotive of all work, when the battery is not charging; as a consequence, also, the dynamo does not act as a drag on the locomotive when starting. The means by which all these operations are performed are exceedingly simple but we regret that the exigencies of patent matters now pending prevent us from publishing them at this time.

The Lewis system is controlled by the Lewis Electric Co., of this city, of which Mr. Henry E. Fanshawe is vice president and Mr. V. H. Bridgeman, treasurer, with Lieut. Lewis as electrician. Besides the car fitted up on the New York Central Railroad, a number of cars on other roads will shortly be equipped so that the system will soon have a crucial test.

NON-ELECTROLYTIC DISSOCIATION.

A CONTRIBUTION to the dissociation hypotheses has been made by M. Wildermann, who regards two kinds of dissociation as possible, namely, electrolytic dissociation into ions, and non-electrolytic dissociation into larger molecular aggregates of the dissolved substance into smaller aggregates. This new assumption which is elaborated in the *Berichte*, xxvi., pp. 1,773–86, appears to be of use, in so far as it is sufficient to explain the divergencies and discrepancies existing between the observed data and numerical values calculated on the electrolytic dissociation hypotheses alone. The author also discusses, in this paper, the electrical conductivity of salt solutions which do not in general obey the dilution law applicable to weak acids and bases. He then discusses the matter mathematically, and deduces formulæ which show a qualificative agreement with the experimental data.

MISS MARY A. HENRY's interesting account of the life work of her father, Joseph Henry will be continued in our pages next week.

MR. JESSE VAN ZILE ANTHONY, manager of the Middletown, N. Y. Electric Light & Power Co. has married Miss Frances James of Jersey City Heights, N. J.

THE TELEPHONE PATENT SITUATION.—I.

WHEN the fundamental Bell patent, No. 174,465 expired on March 7, 1893, it was thought by some that the telephone receiver at least was free, and individuals and companies started cautiously and tentatively to make telephonic apparatus. Those who did so, however, soon had their attention called, by the American Bell Telephone Co., to the structural patent on the receiver of Jan. 30, 1877, which, with the fundamental patent above referred to, was sustained by the Supreme Court. The Bell Company also immediately after March 7, 1893, changed its well worn advertisement, appearing in the electrical papers and elsewhere, to read as follows :—

> THE AMERICAN BELL TELEPHONE CO.,
> 125 Milk street, Boston, Mass.
>
> This Company owns the Letters Patent No. 186,787, granted to Alexander Graham Bell, Jan. 30, 1877, the scope of which has been defined by the Supreme Court of the United States in the following terms :
>
> "The patent itself is for mechanical structure of an electric telephone to be used to produce the electrical action on which the first patent rests. The third claim is for the use in such instruments of a diaphragm, made of a plate of iron or steel, or other material capable of inductive action ; the fifth, of a permanent magnet constructed as described with a coil on the end or ends nearest the plate ; the sixth, of a sounding box as described ; the seventh, of a speaking or hearing tube as described for conveying the sounds ; and the eighth, of a permanent magnet and plate combined. The claim is not for these several things in and of themselves, but for an electric telephone in the construction of which these things or any of them are used."
>
> This company also owns Letters Patent No. 463,569, granted to Emile Berliner, Nov. 17, 1891, for a Combined Telegraph and Telephone and controls Letters Patent No. 474,231, granted to Thomas A. Edison, May 3, 1892, for a Speaking Telegraph, which cover fundamental inventions and embrace all forms of microphone transmitters and of carbon telephones.

This alone did not deter enthusiastic manufacturers of telephones, and it became necessary for the Bell Company to bring suit in Pittsburgh, Pa., against the Shaver Corporation and its licensee company at McKeesport, Pa., praying for an injunction, and citing the patent of Alexander Graham Bell, of Jan. 30, 1877, No. 186,787, as the one infringed. The injunction was promptly granted as were subsequent injunctions against other infringers. The advertisement which is quoted above gives the scope of the patent as defined by the Supreme Court, and, as the patent will expire on the 30th of this month, the claims are here printed in full, in order that readers may learn exactly what will then be open to the public :

CLAIMS.

1. The union upon, and by means of, an electric circuit of two or more instruments, constructed for operation substantially as herein shown and described, so that, if motion of any kind or form be produced in any way in the armature of any one of the said instruments, the armatures of all the other instruments upon the same circuit will be moved in like manner and form ; and if such motion be produced in the former by sound, like sound will be produced by the motion of the latter.

2. In a system of electric telegraphy or telephony, consisting of transmitting and receiving-instruments united upon an electric circuit, the production, in the armature of each receiving-instrument, of any given motion by subjecting said armature to an attraction varying in intensity, however such variation may be produced in the magnet, and hence I claim the production of any given sound or sounds from the armature of the receiving-instrument, by subjecting said armature to an attraction varying in intensity, in such manner as to throw the armature into that form of vibration that characterizes the given sound or sounds.

3. The combination, with an electro-magnet, of a plate of iron, or steel, or other material capable of inductive action, which can be thrown into vibration by the movement of surrounding air, or by the attraction of a magnet.

4. In combination with a plate and electro-magnet, as before claimed, the means herein described, or their mechanical equivalents, of adjusting the relative position of the two, so that, without touching, they may be set as closely together as possible.

5. The formation, in an electric telephone, such as herein shown and described, of a magnet with a coil upon the end or ends of the magnet nearest the plate.

6. The combination, with an electric telephone, such as

described, of a sounding box, substantially as herein shown and set forth.

7. In combination with an electric telephone, as herein described, the employment of a speaking or hearing tube, for conveying sounds to or from the telephone, substantially as set forth.

8. In a system of electric telephony, the combination of a permanent magnet with a plate of iron or steel, or other material capable of inductive action, with coils upon the end or ends of said magnet nearest the plate, substantially as set forth.

While the expiration of this patent this month will free the receiver (which instrument can also be used as an inferior transmitter) there still remain, protected by patents, a number of special forms and modifications of the receiver and certain improvements in magneto telephone transmitters. Quite a number of patents bear upon the shape and arrangement of the permanent magnet or magnets, with reference to the diaphragm,—such as types of "crown magnetos," etc.—while others, like Phelps, No. 222,201 of December 2, 1879, refer to methods of construction conducive to better articulation. Manufacturers of telephone receivers who propose to depart from the regular form, will do well to look up carefully these many minor patents.

The receiver being free, how about the transmitter?

It seems to be thought by some that, because under the operation of Section 4887, of the Revised Statutes, the Blake patents have expired in this country, the Blake transmitter is free; the patents of Francis Blake, however, do not of themselves cover the Blake transmitter; these patents are subordinate to Berliner, 463,569 of Nov. 17, 1891—the famous "Berliner Patent"—and also Edison, 474,231 of May 3, 1892, besides the other two Edison microphone patents of May 3, 1892, numbered 474,230 and 474,232 respectively. Then there is the re-issued patent of Berliner, No. 9,499 of December 14, 1880, upon the induction coil, which has so far been ignored by writers on the telephone patent situation. This patent was originally No. 199,141, and issued on Jan. 15, 1878. It therefore has one year to run, during which time the induction coil can not be used without infringement. Then there is the patent of Watson, No. 217,561, of July 15, 1879, upon the attachment of the polished button to a metal back, which also has a bearing on the question. Section 4887 of the Revised Statutes has been referred to above and, as it has a most important bearing upon the subject, it is printed here in full, although it is doubless familiar to many readers.

SECTION 4887, REVISED STATUTES OF THE UNITED STATES.

No person shall be debarred from receiving a patent for his invention or discovery, nor shall any patent be declared invalid, by reason of its having been first patented or caused to be patented in a foreign country, unless the same has been introduced into public use in the United States for more than two years prior to the application. But every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than seventeen years.

The fate of the Edison patents under this section of the patent law will not be known until a final decision in the Bate Refrigerator litigation; both the life of the Edison lamp patent and the Edison transmitter patents hang upon the decision in this case. What has still to be decided is, what bearing, if any, has the date of application of the American patent, with reference to the date of application of the foreign patent? In interpreting Section 4887, the Circuit Courts have held that the dates of domestic and foreign applications were irrelevant. It is now contended in the new Bate case, that "previously patented in a foreign country" should be taken to mean *previously applied for* in a foreign country. The case of Bate Refrigerator Co. *vs.* Sulsberger, *et al*, decided June 7, 1893, *pro forma* in favor of the defendants, according to previous Circuit Court opinions, was appealed. It was expected to be argued, in the United States Circuit Court of Appeals, in New York, in December, but has been deferred.

In the case of the Edison transmitter patents the application was made in the United States Patent Office prior to the foreign application; yet the English patent was issued, ran fourteen years and expired, before the United States patent was issued.

For a great part of this period the applications of Berliner and Edison were in interference. As is well known, during these many years of delay in the Patent Office, the Bell Company owned both sides of the interference. Now if, in the Bate Refrigerator Case, the Court shall decide that the date of application of the United States patent controls, then the Bell Company will have the protection of the Edison patents for seventeen years from May 3, 1892, and this protection it will have even though it be defeated in the government suit now pending against it in Boston to annul the Berliner patent. In the Bate Refrigerator case, it is generally thought that the fate of the Edison lamp patent is the principal thing to be decided; the Westinghouse Electric and Manufacturing Co. are supposed to be interested in confirming the interpretation that Section 4887 means that the date of issue controls; while the General Electric Co., the owners of the Edison lamp patent, contend that the date of the United States application as compared with that of the foreign application controls. While these two companies and the general public are interested in the Refrigerator case from the incandescent lamp point of view, the American Bell Telephone Co. and the public (if the public only knew it) are a thousand fold more interested from a telephone transmitter point of view; and it is a significant fact that Mr. F. P. Fish, counsel of the General Electric Co., is also of counsel for the American Bell Telephone Co. The latter company is not known in the case, but in the event of a favorable decision it will profit far more than will the General Electric Co.

It is assumed, in some recent articles on this subject that the Edison transmitter patents are admittedly void. If the existing interpretation of Section 4,887 by the Circuit Courts had been finally approved by the Supreme Court, the above assumption would stand.

It has been erroneously assumed that the Bell Company desired delay in the Government suit to annul the Berliner patent; in an editorial in THE ELECTRICAL ENGINEER of January 3, it was pointed out that such was not the case, and why it was not. The fact is, on the contrary, the Bell Company has every reason to desire a decision at as early a date as possible; while Judge Taylor, of Government counsel, says that Mr. Storrow (of Bell Co.'s counsel) and Attorney General Olney are trying to hurry him, but he won't be hurried. The truth of the matter is that the case is now going forward with all possible dispatch in Boston, and will probably come to argument in May of this year. It is a question whether the Bell Company are justified in stating in their advertisement that the Berliner and Edison patents "embrace all forms of microphone transmitters and of carbon telephones," for the reason that a form of such instrument may be conceived that does not depend for its action upon the variation of "pressure between electrodes in constant contact." It is doubtless true that no transmitter patent has as yet issued that does not include dependence upon variable pressure for its action, but it cannot be predicated or predicted that a transmitter, and a carbon transmitter at that, may not be invented that shall act in an entirely different manner.

As no single article of moderate length can do justice to the transmitter patent situation, it may be appropriate to close this instalment with the claims in full of the Berliner and principal Edison transmitter patents.

Claims of Patent of Emile Berliner, Application filed June 4, 1877, Patent issued Nov. 17, 1891:

1. The method of producing in a circuit electrical undulations similar in form to sound-waves by causing the sound-waves to vary the pressure between electrodes in constant contact so as to strengthen and weaken the contact and thereby increase and diminish the resistance of the circuit, substantially as described.

2. An electric speaking-telephone transmitter operated by sound-waves and consisting of a plate sensitive to said sound-

waves, electrodes in constant contact with each other and forming part of a circuit which includes a battery or other source of electric energy and adapted to increase or decrease the resistance of the electric circuit by the variation in pressure between them caused by the vibrational movement of said sensitive plate.

3. The combination, with the diaphragm and vibratory electrode, of a rigidly-held opposing electrode in constant contact with the vibratory electrode, substantially as described.

4. In a telephonic transmitter, a vibrational plate made concave for condensing the sound, substantially as set forth.

5. In a telephonic transmitter, a vibrational plate provided with one or more apertures, as and for the purposes set forth.

6. A speaking-telephone transmitter comprising a diaphragm or disc sensitive to sound-waves, combined with a rigidly-held but adjustable electrode in contact with the same, whereby the electric current is transformed into a series of undulations corresponding with the vibrations of said diaphragm.

Claim of Patent of Thos. A. Edison, Application filed July 20, 1877, Patent issued, May 3, 1892. Patented in England, July 30, 1877, No. 2009:

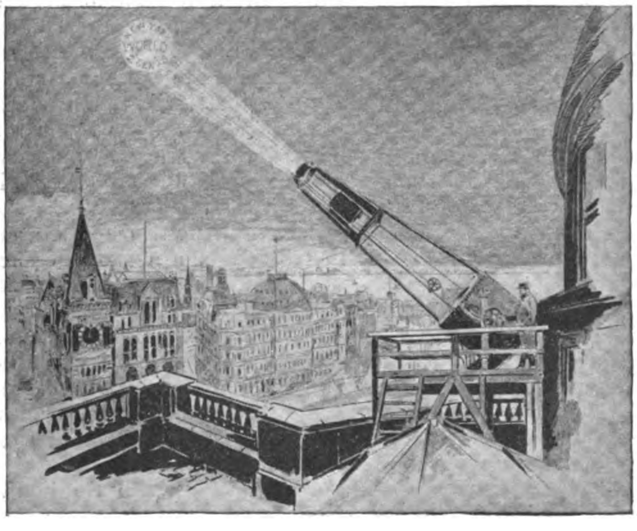
Claim:

In a telegraphic apparatus operated by sound, the combination, with the diaphragm, of one or more contact-points of plumbago or similiar inferior conductor in the electric circuit, whereby the rise and fall of electric tension is proportionate to the pressure exerted upon the said point or points by the diaphragm, substantially as set forth.

THE ROGERS ELECTRIC CLOUD PROJECTOR.

One of the closing electrical features of the World's Fair at Chicago was the Rogers electric cloud projector which, placed on the roof of the Manufactures Building informed the gathering multitude of the number of visitors during the day and drew their attention to numerous other things by projecting words and pictures on the clouds. The apparatus used at Chicago has now been transferred to New York by its inventor, Mr. L. K. Rogers of the Brush Electric Co. It has been placed on the roof of the Pulitzer Bdg., on Newspaper Row, opposite the City Hall Square, where its announcements now attract the attention or thousands on favorable nights.

Our illustration made from a drawing for which we are indebted to the *New York World*, gives a very clear idea of the apparatus employed. It consists of an electric focussing lamp, whose rays are projected outwardly by a 30-inch Mangin reflector. The arc itself is not placed in the focus of the projector but some distance forward of that point, so that the rays are directed upon a 10-inch condensing lens which brings them into parallelism. At the end of the arm projecting from the cylindrical case is placed a focussing lens, the position of which can be regulated by means of the hand-wheel and chain shown.

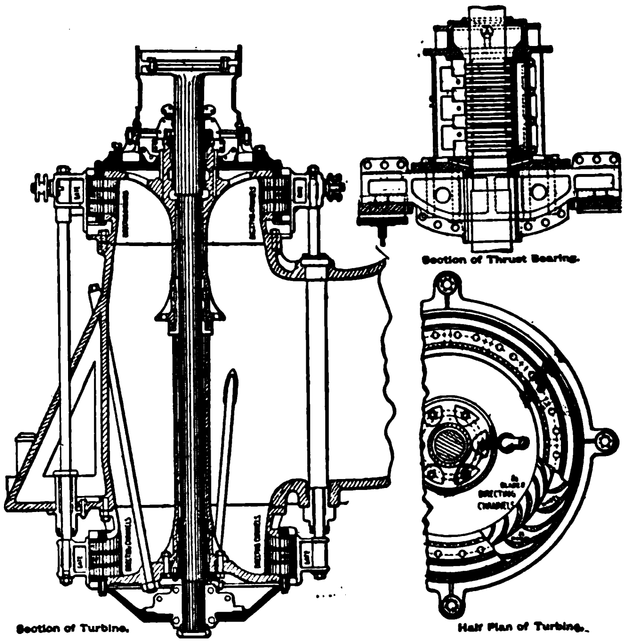


THE ROGERS ELECTRIC CLOUD PROJECTOR.

The design to be projected on the clouds is cut out of card board and this stencil is inserted in the path of the rays close to the first lens. The whole apparatus is mounted on a swivel base and trunnions so that it can be revolved and pointed in any direction and the design thus made to follow a passing cloud. The electrical features have been worked out by Mr. Elmer E. Sperry. The lamp employed takes a current of over 150 amperes and its beam is said to rival in intensity that of any search light thus far used. All that Mr. Rogers needs to do is to wait till the clouds roll by. Should they refuse to roll, however, he can create his own clouds by steam, smoke bombs in the air, etc.

THE NIAGARA FALLS ELECTRIC POWER PLANT.

The paper of Prof. Forbes, concluded in our last issue sets forth the electrical details which will be adopted at Niagara Falls in the great power transmission plant now in course of construction, and supplementing this we give below further details regarding the hydraulic arrangements and methods of conduit wire distribution.



FIGS. 1, 2 AND 3.

The units in the 50,000 h. p. station now being erected by the Niagara Falls Power Co. consist of 5,000 h. p. Westinghouse alternating dynamos, each with its revolving field directly connected to the vertical shaft of a 5,000 h. p. twin turbine, built by the I. P. Morris Co., of Philadelphia, from designs furnished by the Swiss firm of Faesch & Piccard, and shown in Figs. 1 and 2 of the accompanying illustrations, for which we are indebted to our excellent contemporary *Power*. They are of the Fourneyron or Boyden type, designed to develop 5,000 h. p. under about 140 feet head and at 250 revolutions per minute, and are made of cast bronze of the same quality as that used for the propellers of steamships.

The main canal, on the west side of which the power station is located, is 188 feet wide, and 17 feet deep at the river, narrowing to 116 feet in width, but preserving the same depth throughout its length of 1,260 feet. The water will be carried in the canal to a depth of about 12 feet. The sides of the canal are built of solid masonry, seven feet thick at the bottom, tapering to three feet thick at the top, on which is a coping two feet and a half wide. From this canal the water is taken through a separate inlet for each wheel, and carried through a penstock seven feet in diameter into the centre of the turbine. The weight of the vertical shaft and the attached portions of the dynamo, amounting to about 152,000 pounds, is taken care of by closing the bottom of the casing so that the water cannot act downward upon any of the parts attached to the shaft, while in the upper end of the casing are apertures through which the water can act upon the under side of the disc carrying the movable blades of the upper turbine and relieve the bearings of the weight of the shaft. In this way the weight of the water column is sustained by the stationary portions, and the pressure due to the head made to act upward for supporting the weight of the revolving shaft, which is thus nearly in the condition of a shaft spinning upon the water. The area involved is so proportioned that when the wheels are lightly loaded the upward pressure will be some 2,000 pounds in excess of the weight

of the shaft, and when the wheels are running at full gate about the same amount less than the weight of the shaft, on account of the lesser pressure in the casing. This variation in pressure and direction is taken care of by a thrust bearing shown in section in Fig. 3.

The shaft consists of a steel shell about a foot in diameter, with smaller solid portions for the journals.

The dynamos are constructed upon the Tesla two-phase alternating current system, with stationary armature and revolving fields, and are designed to generate a potential of 2,000 to 2,400 volts, which will be increased or diminished by step-up or step-down transformers for transmission or local use. Motor generators will be run for the production of continuous current when required, so that the station will be able to furnish continuous or alternating current of any potential. Two-phase Tesla motors will be used. The station is designed eventually to comprise ten of these units and the wheel pit and building will be extended toward the river and new wheels put in as required.

The power house is being built of stone, with a steel frame, and lined with enameled brick. The steel roof trusses of over 60 feet span rest upon steel posts, and a 50-ton traveling crane commands the entire floor.

The distribution will be through underground conduits extending in various directions from the station in the principal points of service. Fig. 4 shows the construction of one of these, while Figs. 5 and 6 are sectional views in outline. The conduit is 5 feet 6 inches high by 3 feet 10 inches wide inside, and is built with 12 inches of Portland cement and gravel, and backed up by about one foot of masonry at the bottom and extending up the sides about 3 feet. The conductors will be carried on insulated brackets on both sides. A track extends throughout the length of the conduit, upon which an electrically propelled car will carry the linemen between wire screens that protect them from the conductors and allow every portion of the line, brightly illuminated by the passing car, to be thoroughly inspected with absolute safety. The brackets are placed 30 feet apart.

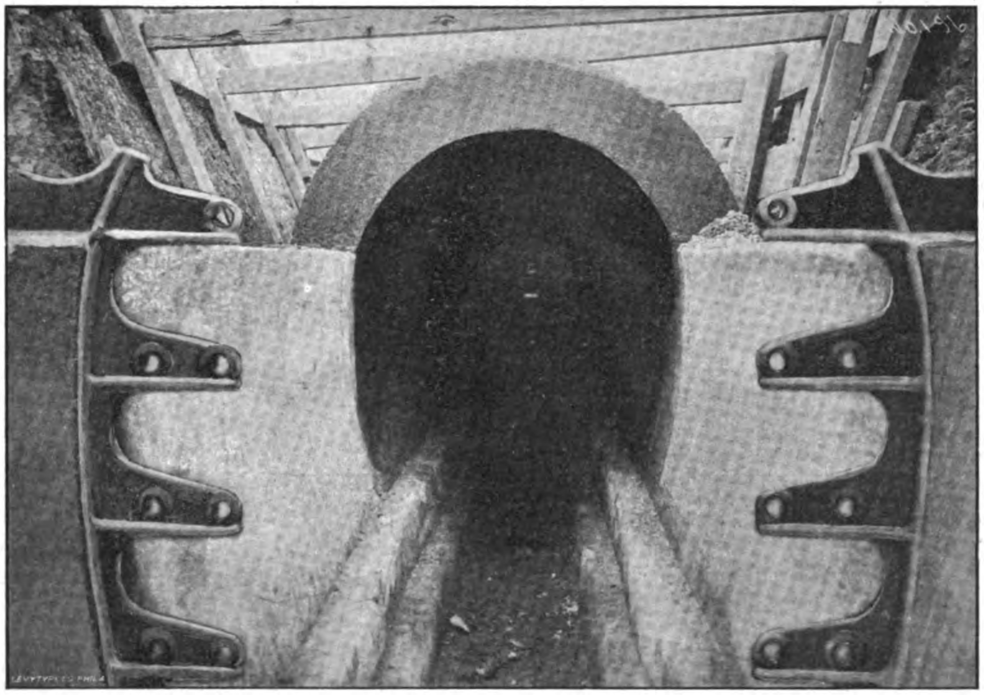


FIG. 4.—THE CONDUIT IN COURSE OF CONSTRUCTION.

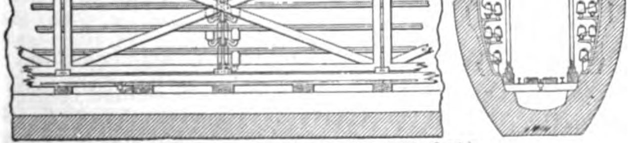

Longitudinal and Cross-Section of Electric Wire Conduit.

FIGS. 5 AND 6.

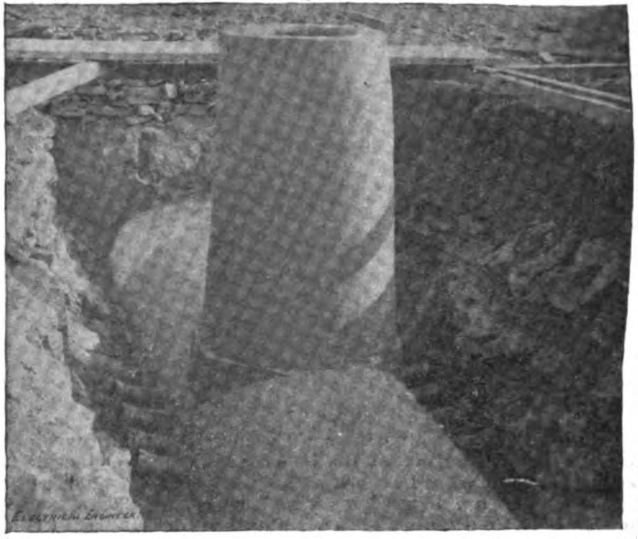

FIG. 7.—MANHOLE AND SIDE DUCTS, NIAGARA POWER DISTRIBUTION.

Fig. 7 shows one of the manholes which are placed at intervals of 400 feet. At the bottom will be seen the small outlets for tapping the conductors in the conduit.

The Niagara Falls Paper Co. have already arranged to take 3,000 h. p., and the Pittsburg Reduction Co., about the same amount for manufacturing purposes and lighting.

THE NIAGARA TRANSMISSION PLANT.

THE following is a special dispatch from Buffalo:

The real estate men of this city are considering plans for celebrating on a royal scale the inauguration of the use of the Niagara Falls electric power in Buffalo. The plan most favored is to issue letters of invitation to President Cleveland and his Cabinet, Senators and Congressmen, Governors of States, and other high officials, all the eminent electricians of the world, and representatives of the press from everywhere. The wire conveying the current is to be connected with one of the large manufacturing plants near the city line and the machinery set in motion by the touching of a button.

ELECTRIC TRANSPORTATION DEPARTMENT.

ELECTRIC CHAIN TRACTION FOR CANALS.

BY

Jules Neher

Among the notable questions of the hour is the improvement in the method of propulsion on the Erie canal. Various schemes have been brought forward having for their object the replacing of the "wave generating, bank destroying" propeller. The purpose of these lines is to discuss a system described in The Electrical Engineer a few weeks ago and to suggest a scheme that has done good work in other countries.

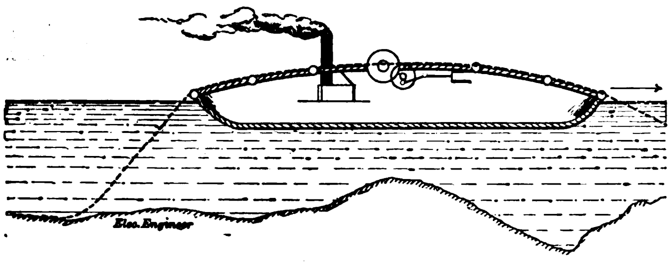

Fig. 1.

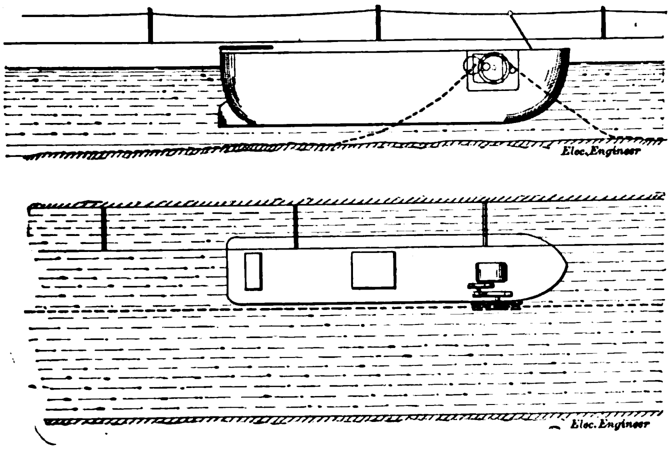
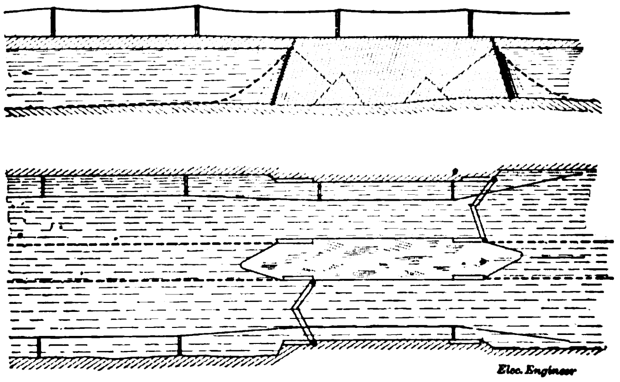
The cheapest and simplest equipment naturally is the propeller used either in connection with steam engines, or, better, driven by electric motors. The serious objection against this system is its action on the water and subsequently on the banks of the water way. A very ingenious and interesting method to overcome this difficulty has been described in the issue of The Electrical Engineer, December 20, 1893, as the "Davis' Electric Canal Boat Towing System."

The objection against this system—an objection which will undoubtedly make it prohibitive—is the enormous cost; because, if you have a canal you do not want two railroad tracks, hauling locomotives and boats. If you want to build on land a double track road is cheaper than two single tracks, and rolling traffic is cheaper than floating. Naturally we have to consider that one boat will carry the load of a whole train but a train will run about ten times as fast as a boat. As soon as we would have track construction and rolling material and canal maintenance then all the advantages of this slow transportation of large quantities will fall out of consideration when compared with the quick transport of small quantities on land either by steam or by electricity.



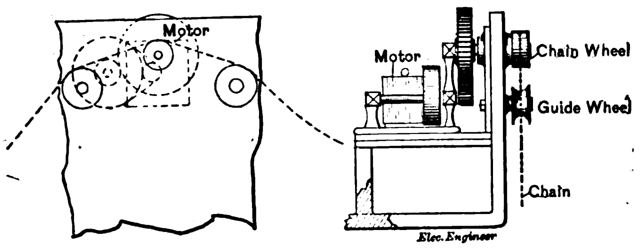
Figs. 2 and 3.

On a number of rivers in Europe, for instance the Seine in France or the Main in Germany, another system has been employed very successfully for many years, namely, chain traction. We might call this a method of cable traction with stationary cable, the boat pulling itself forward along the cable by means of a hoisting or hauling device. In the cases mentioned this towing device is located in the centre of the boat, the chain is taken up in front, runs over the hoist drum and leaves the boat at its end. The accompanying diagram, Fig. 1, will explain the arrangement.



Figs. 4 and 5.

On the Erie canal it will probably prove to be more economical to provide a number of boats with the electric equipment, than to use only a few electric tugs towing a whole train of freight boats, and this system would make necessary an arrangement that can easily be mounted in the canal boats as they exist to-day. Therefore it would be advisable to have the towing device at the side of the boat and this idea is shown in Figs. 2 to 7. The vertical iron bed plate could be mounted inside of the boat and secured to several points aft by wrought iron tension bars, which would distribute the side pull symmetrically with the axis of the boat. Motor and gearing could easily be mounted inside of the boat without taking up much valuable space. From lock to lock the chain would have to be anchored at about the height of the chain wheel, so that the boat coming towards the lock can easily run off the chain and in leaving the lock take it up again, about in the same way that cable cars do when going off from one cable section to another one.



Figs. 6 and 7.

Possibly the chain could be used as an electrical return circuit, thus saving half the amount of copper in the overhead-trolley line; and particularly there could be no objection against a ground-return, if we replace the chain by a wire-cable; in this case a friction-wheel device, that is to say, a revolving grip, would do the same service as the chain-wheel.

It seems to me that a system like this would be superior to a sheme necessitating a track system and towing locomotives. But commercially it could compete with the propeller system only in case this has to be discarded on account of its destructive action on the canal banks.

A NEW JERSEY ELECTRIC RAILWAY CONSOLIDATION.

The Consolidated Traction Company has secured control of all the street railway lines operated by the New Jersey Traction Company and all the stock of the latter company has been transferred to the former with the exception of one share apiece, to be held by the directors of the New Jersey Company, in legal formality, to keep the organization alive. All the leases of the New Jersey Traction Company have been ratified by the Consolidated, and the securities of leased lines are thus put on a more solid basis than ever before, while the Consolidated Traction Company becomes practically the owner of all lines in Newark, Jersey City and Elizabeth, except those of the North Hudson, in Jersey City; one line in Elizabeth, and the South Orange in Newark.

THE STETSON CONDUIT RAILWAY.[1]

BY ALBERT STETSON.

OVER a year ago I became engaged in some attempts to solve the conduit railway problem at Coney Island. This system was not a sudden idea, but had been a gradual development. For nearly two years it has been being gotten into shape, and a number of inventors have contributed their share towards its completion and success. The original idea of the box used down there, and the working of it out to its completed form belongs, I may say modestly, to me. Among those who have worked upon the details of the invention, I may mention Mr. G. T. Woods, Mr. C. S. Van Nuis, and Mr. John H. Dale; but whatever success it has attained has been due to the suggestions and inventions of Mr. John J. Green, who brought to the work the mind of the inventor and the skill of the trained mechanical and electrical engineer.

Knowing what had been done, having spent four months in the Patent Office, having examined the traction question on the whole Continent of Europe, we set to work to construct a system that should avoid the defects inherent in other devices. To strengthen their weak points, to make an all-the-year-round system, was our object. I assert with the utmost confidence that we have succeeded. We have, on three occasions, filled our conduit to the top with mud and water, burying out of sight conductors, contact boxes and all the devices.[2] Mud of the consistency of paste was used, and the report of a disinterested electrician, not known to me personally, brought there by the editor of one of our leading electrical journals, shows that the system was in no manner affected. With the shoe of the car in the mud, with boxes entirely submerged, the ordinary measuring instruments failed to show anything but the best insulation, and no disturbance of traffic would arise with 50 cars in a conduit filled with mud and water. No such condition would ever present itself in railway work, but a space of several hundred feet might get full of mud, snow or water, and the successful system must not be disturbed by such trifles. We made our mud test, not once, but three times. When the last test was made our boxes had been under the mud four days; yet it is to those boxes that Mr. Stevenson's report refers. Four days' submergence is a terribly hard test, but if the line then works perfectly, there is absolutely nothing to apprehend from an occasional filling up during a shower.

A conduit is used, similar to that of cable roads, but nothing like so large or expensive. With our improved shoe, a conduit two or three inches wide and seven inches deep will answer perfectly. In the slot of the conduit, attached to the car, runs a shoe extending nearly the length of the car.

The shoe is so supported that should the car leave the track it detaches itself immediately and remains on the top of the conduit. It cannot get caught, as the cable grip sometimes does, and drag the car along through crowded streets at a dangerous speed. The shoe is somewhat like a cigar in shape, so as not to give any sharp blow to the contact arms. The sides of the shoe are formed of conducting material, insulated from each other and perfectly flexible, so as to follow any curves. The shoe can be attached to and detached from a car in five to ten seconds. In the conduit are placed two insulated cables, a metallic return being used. This I regard as necessary to ensure perfectly safe working. These cables run into and through contact boxes placed at intervals of ten feet on each side, and arranged diagonally opposite, so that the distance between the boxes is about five feet.

The main is carried into the box and the lead and insulation removed for about two inches. On this bared cable there is placed a brass clamp with two upwardly projecting tongues. The contact-making portion of the device is a vertical rod, having, at its upper end an arm projecting into the conduit, and at its lower end a brush adapted to be brought into contact with the tongues attached to the cable. This rod and its bearings must, of course, be properly insulated from the contact box. When no car is passing, the brush is out of all electrical connection with the current conductor, but when the shoe on the car reaches the arm projecting into the conduit, it swings it to one side, bringing the brush on the rod into contact with the tongues fastened to the conductor, and the current passes to the motor on the car. As soon as the shoe on the car has passed the box, a torsion spring forces the rod back into its normal position, and that box is dead. The box is filled as far as it can be without interfering with the movement of the brush with solid paraffine, and above that with "transil oil." This makes excellent insulation. Of course the spindle, which at times becomes "alive," and its bearings, are thoroughly insulated from all parts of the box and cable. Nothing can be better than an insulated cable, covered throughout its entire length with a highly resisting material, and at the points where current is supplied to the car an insulation practically infinite.

No accident to persons or animals appears possible with this system. To avoid sparking within the box, the ends of the shoe are made of insulating material, thereby establishing mechanical contact within the box before the metallic portion comes into contact with the arm, and also holding the inside contact after the current ceases to flow to the motor. This is an important feature, for without such an arrangement the brushes would soon burn out, the oil become carbonized and the boxes useless.

Thus far I have described the box that we used at the Island, but it has long since been consigned to the usual receptacle for the rejected productions of progressive inventors. It did its work and did it well, it pointed the way to better things, and we have several forms of box, entirely obviating the defects in the first. The number of working parts has been reduced, and we now have the device brought down to its simplest form. I regret that it is not possible for me to show these improvements, but patents have not been obtained on some, and on others not yet applied for.

As a guide for future investigators, I will enumerate the best features and defects of the old box, as I understand them. 1st. Its insulation was excellent, that is, the theory of its insulation was. But oil insulation is in many cases a fraud, a deception and a snare. The best oil insulation is not so good as that of air containing 80% of moisture. Oil and water, perhaps, won't mix, but oil will attract moisture, and the two will make an emulsion that will cause the investigator much sorrow and mental anguish. Ordinary paraffin oil, even the highest grades obtainable, contains a great deal of water which, in a device like this, will cause disastrous short-circuiting. Transil oil seems the best for the purpose. At Coney Island, before we adopted transil oil, our boxes would go wrong, in spite of all we could do, and we only discovered the trouble by putting some of our oil in a bottle to settle over night, and in the morning found an abundance of water in the bottom. Solid paraffin is the only substance that we found capable of withstanding the action of paraffin oil, and it must be the refined variety, such as is sold in hard, white cakes. Its use even was discarded, for when the water would work down the spindle through our imperfect stuffing box, the solid layer formed a bed for the moisture to rest upon, and being close to our brush, it short-circuited the box. It is better to let the moisture settle to the bottom of the box out of harm's way. I don't think oil should be used on account of its insulating properties, but for keeping the working parts from rusting. 2d. Our old box was made in several parts (a mistake, remedied in our new one-piece box), the joints required planing, an expensive operation. Paraffin oil is difficult stuff to hold, going through almost everything. In the joints we used oil paper, screwed them together as tightly as possible, but the oil softened the paper and the boxes leaked. This we remedied by painting the joints with "Insullac," which withstood the oil excellently. 3d. Our stuffing box was a crude device, and did not in many cases, keep out the water; but this is a simple mechanical affair remedied in our new boxes. 4th. A torsion spring is not so good as a straight one, nor so reliable in its action. 5th. We had a short brush in our box, when a long one should be used. Flexibility and sure contact are thereby secured. 6th. It was a mistake to have the two upwardly projecting tongues; one contact is the thing, and the brush always resting against it when the shoe touches the arm. Otherwise there will be a break on reversing, the consequent "frilling" of the brushes, with carbonization of the oil. 7th. To make an oil-tight joint between the cable and the box was almost an impossibility. We taped the cable where it entered the box, but when it was tightened up there was often contact between the lead covering and the box. 8th. The box is too large. 9th. Great care must be used in selecting and laying the cable. A slight defect gives leakage; this decomposes the alkaline earths; chlorine and caustic soda are perhaps produced, and the cable eaten away. Every joint must be carefully made and carefully sealed. Some one may say that it is impossible, but I answer it is the duty of the supervising engineer to see that it is properly done. If any one thinks this cannot be done, he is not my ideal engineer, and certainly does not want to meddle with electric conduit railways. These are the defects, but we have cured them all in our new system. The excellent principle of the old box has remained untouched by long experiment, the laterally yielding arm being the only form likely to answer this purpose.

I believe that our road has solved the question of conduit traction. I have not meant in my review of other systems to be in the least unjust to other workers in the same field. I only take my stand on other well-established principles, keep strictly to the laws of nature and electricity, take our climate as it is and our streets as we find them, and I assert, without fear of successful contradiction, that any road to succeed must be laid down practically on these lines.

THE PROSPECTS OF ELECTRIC HEATING.

GRADUALLY but surely that later development, electric heating, is forging to the front and it must soon command more serious attention than has been bestowed upon it up to the present. The impression has prevailed that while for purposes requiring small amounts of heat, and especially where such heat is intermittently applied and where the temperature required is not very high,—such as in electric cooking apparatus, soldering irons, etc.,—the electric method is fairly economical and eminently convenient; but that for any extended application on a large scale and involving high temperatures, electrically generated heat is out of the question. While we have been favored with calculations on the economy of such minor, domestic applications as those above cited, no one, so far as we are aware, had undertaken to analyze the prospects of operating smelters and blast furnaces by electrically generated heat. At the first blush such a plan would indeed seem to possess scarcely any points in its favor and to be in the line of the general, foolish drift nowadays, to do everything by electricity. More especially does it seem unwise when it is taken into consideration that against the direct application of the fuel to the body to be heated, in one case, we have the unquestionably roundabout electric method involving a furnace, a boiler, a steam engine and a dynamo. But in spite of all this, is the electric blast furnace so far removed from practicability that it is not worth considering for the present, or even for the future? The conditions involved are very tersely put by Mr. I. L. Roberts, in an article which appears elsewhere in this issue and which will repay close study. Mr. Roberts has not contented himself with mere calculations, but bases his conclusions on the results of actual experiments. It is true, that they have been made on a small scale; but the very fact that they were on a small scale and yet showed such unmistakable advantages in favor of electric heating would fairly lead to the inference that with larger apparatus the gain would be still more marked. While the blast furnace itself may not be a thing of the immediate future, Mr. Roberts' experience has sufficiently demonstrated that for many other applications such as brass smelting, carbon baking and similar operations the electric furnace is well able to hold its own against the methods now used.

THE "NOVAK" LAMP NOT ENJOINED.

ALTHOUGH Judge Shipman handed down on Saturday, Jan. 6, an opinion granting the motion of the General Electric Co. for a preliminary injunction against the Waring Electric Co. for infringement of the Edison patent by the "Novak" lamp, with its bromine atmosphere, he has followed up his decision by refusing to stop the manufacture of the lamps peremptorily. The uncertainty or doubt that runs through the opinion seems to have gained upon the Judge's mind during the week, and when the case came up on Jany. 13, for settling the terms of the order, he granted a stay pending an appeal, under bonds of $10,000, to the Circuit Court of Appeals, the appeal being set down for January 23, at New York. He did this in spite of the offer of the General Co. to place itself under bonds if the injunction were issued. Judge Shipman is evidently more concerned to be fair than consistent, and does not propose summarily to block any real improvement in the art of lamp manufacture. The Waring Co. are now free to pursue for a while, undisturbed, the manufacture and sale of a lamp whose qualities are well illustrated in Prof. Robb's tests cited by the Judge; and we now have the remarkable spectacle of two concerns making incandescent lamps under the nominal restraint of bonds. We have no doubt that the Waring Co. and its agents will make the most of their opportunity.

AMERICAN BELL TELEPHONE PATENTS.

As the magneto telephone of the American Bell Telephone Company—the instrument commonly known as the "receiver"—becomes public property at the beginning of February by the running out of the patent, the interest as to the immediate future of the telephone industry is widespread. Not only do people want to know how soon they will get cheaper telephones, but manufacturers who wish to supply the market are anxious to know how far they can go legitimately and honestly. There has been a great deal of misinformation published on the subject, and much of it has been of a most mischievous tenor. The telephonic art is far from being wholly open. The American Bell Telephone Co. is strongly intrenched within patents that rise one behind the other like concentric fortifications, and it has not spent its existence in a supine and lazy enjoyment of fat profits to be reaped only for a season. But the lapse of the fundamental patents renders some things possible, in some fields that the company has neglected or chosen to disdain. With the object of indicating the limits of the *mare clausum* and the possibilities of the open sea of telephony, we have begun in this issue a series of articles that have been very carefully prepared, covering the whole ground of telephonic patents and telephonic apparatus. Where deemed important and pertinent, the language of the patent claims bearing on the situation is quoted in these articles. We shall be glad to have our readers assist us in the discussion of the subject, and will endeavor to answer any inquiries that touch vital points.

THE NEW BUCKEYE LAMP.

If Necessity is the mother of Invention then surely she has shown herself a most prolific parent in the domain of incandescent lamps. In some respects the history of the efforts to create a lamp outside of the claims of the Edison patent bear a close analogy to the similar attempts in respect to the Bell telephone, but with this difference: That while in the latter case but two essential elements were involved, namely, a magnet and a juxtaposed diaphragm, in the former the inventor has had no less than four elements upon which to ring the changes, involving (1) a vacuum, (2) an all glass receiver, (3) a carbon filament, and (4) leading-in wires. As a consequence we have had non-carbon filament lamps; "gas" lamps, that is, lamps containing a residual, inert gas; "stopper" lamps, and still others involving variations on the first three elements above enumerated. The leading-in wires, however, were employed in all the above types, and if we except the ingenious Diehl induction lamp, no attempt seems to have been made to work on this apparently indispensable feature of an incandescent lamp. The new Buckeye lamp described on another page will therefore prove of interest as showing the most recent efforts in a struggle which is probably without a parallel in the history of inventions. It is hardly to be expected that the owners of the Edison patent will permit the makers of the new Buckeye lamp to remain long in the unmolested enjoyment of the fruits of their labor and hence we look forward to lengthy arguments on the question of whether a conductor in powdered form can be construed as the equivalent, in law, of a solid wire.

LABOR, EDUCATION AND CAPITAL.

One of the most interesting and noteworthy steps taken in this city by a trade organization is that of which note was made in our columns last week, namely, the arrangements for a course of lectures to the Electrical Workers as part of the University Extension scheme. It is to be hoped that the trial may prove highly successful and useful. Labor has its duties as well as capital has, and these movements are an evidence of very high motives on the part of working men, and of ambitions than which none nobler can enter the human breast. We are certainly entering on a new period of industrial development when an old institution like Columbia College can thus work so closely with a trades union. We cannot forbear noting the report of another remarkable manifestation of the the trial of new principles, at Pittsburgh. Loans of money are being made there by the Window Glass Workers' Union to some of the employing manufacturers to enable them to tide over business troubles. It is said that money has been released from the organization's treasury amounting to tens of thousands of dollars in this manner, and that the applications of a number of employers are under consideration and will probably be granted. By this means several factories have been enabled to start that would otherwise be idle, and some have been kept in operation that might have had to stop. We can only regret that the electrical workers were not able to do as much for some of the electrical factories as their glass-making confrères have done in that line of industry.

Conduit Railways.

The contribution recently made by Mr. Albert Stetson to the proceedings of the Institute is of practical value. It not only includes a survey of what has been attempted and done in the development of conduit railways, but gives an excellent description of the work done by Mr. Stetson himself last year at Coney Island. These are bad times in which to get a capitalist to display the courage of his convictions, but it is a pity that capital could not be induced to back some such conduit railway enterprise as Mr. Stetson advocates. Then we should all know how much there is in it, and the chances are that the promoter would reap a rich reward. The conduit system would at least show up as well as the cable is now doing in New York City. The cable is a great boon, but we question whether a conduit system would have shown as many disasters and delays.

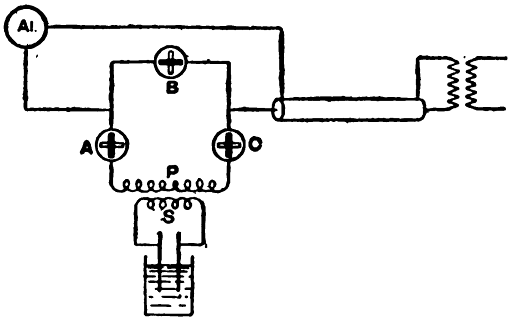
MISCELLANEOUS.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.—V.

The following is an abstract of the discussion on Prof. George Forbes's Paper on "The Electrical Transmission of Power from Niagara Falls," which took place at the Institution of Electrical Engineers.

DISCUSSION.

Dr. Fleming, in opening the discussion, said it was not always that engineers were to be found who were able or willing to take them into their confidence during the constructive stage of their work, and to tell them not merely what they had done, but what they were proposing to do. He would confine his remarks to two points, and the first was the difficulties which might be expected to appear in all cases where electrical transmission of power was conducted over long lines having capacity and self-induction. These difficulties were not merely hypothetical things which were discussed by Professors, and might, therefore, be safely neglected when coming to practice, but were exceedingly real, and capable of giving rise to very disagreeable and dangerous effects. One of the great risks which had to be avoided in the construction of these lines was the presence of pressure effects, which occurred when the lines were suddenly connected to, or disconnected from, the machines. Prof. Forbes was quite right in saying that under those circumstances surgings were set up in the cables and in the machines, and that the pressure might become almost anything they pleased; it might become scores, if not many more times greater than the working pressure; in fact, it was impossible to say under some circumstances what the pressure actually did become, and under those circumstances it was of no use to say anything of failure of insulation, for no insulation would be sufficient to withstand the pressures that were brought against them. The methods by which they could be controlled had only to be known to be adopted. As Prof. Forbes had mentioned that those difficulties had been got over at Deptford, there could be no objection to his telling them the method adopted by his colleague, Mr. D'Alton, in consultation with himself and others. The way in which it was done now was this: The cable was never suddenly connected, but a transformer was placed in the main, as shown, and that transformer had on its secondary circuit an arrangement by which it could be gradually short-circuited. A water resistance was generally employed, but it might be carbon resistance. The first process of connecting the trunk main was to keep the switch B open and close A and C, the transformer being open-circuited on the secondary side. Under these circumstances the transformer offered a considerable impedance to the flow of current, and that nullified the capacity effect in the main. The next step was to gradually short-circuit the secondary circuit of the transformer, reducing the impedance of the transformer. When completely short-circuited the switch B was closed, and then the switches A and C were opened, and the transformer was disconnected from the main. In switching off exactly the reverse took place. When dealing with long concentric cables the capacity might reach a very high value—one-third of a microfarad a mile. It was almost impossible to get a cable, if it was concentric, that had not a capacity effect. If they were to adopt a pressure of 20,000 volts, and a frequency of 100, which was probably what they would have done had they started this enterprise in England, and a capacity of one-third of a microfarad with 18 miles of cable, the capacity current in that cable would be 72 amperes when nothing was connected at the other end. That could be easily calculated from the formulæ he gave some time ago. The capacity of that capacity current to do work, or rather mischief, was proportional to the square of the current and to the frequency. Hence the advantage of low frequencies, for the capacity was something enormous when they came to long lines. Concentric cables were, therefore inadmissable for long lines. He thought there was great safety in using an artificial load in putting machines into and out of parallel. In all Continental stations they did so. When he (Dr. Fleming) was at Rome last Easter he spent a long day with Prof. Mengarini at Tivoli, and the latter allowed him to experiment with the machines there as much as he pleased. They had an artificial load which took up 300 h. p., and this artificial load was made to resemble as closely as possible the real external line. The process of putting the machines in was this: First of all they put them on to the artificial line, and adjusted the incoming machines so as to give exactly the required current and volts. They then put on two machines and divided the current without any difficulty; then a third was put into parallel, and then a fourth and a fifth. They were taken out one by one by reversing the process. That artificial line was used in all the Ganz stations, and he thought Prof. Forbes was very wise in making provision for it in dealing with his machines. It was curious that they had not adopted it much in England. He did not know any place where it was used; yet at the same time he hardly knew any large alternating stations on the Continent where it was not done. In the next place he would say one word on the question of pressure. He was very glad to hear Prof. Forbes say he never intended the primary circuit to be opened. But the question naturally occurred, would not the primary circuit sometimes open itself? In other words, what was going to be done in the way of main fuses? That was really a serious question in dealing with these pressures. What kind of main fuses did Prof. Forbes intend to adopt? In his Paper he mentioned a transformer the secondary of which had a working arrangement which would gradually introduce impedance if the current rose above a certain value. He trusted that that arrangement would be found to work well; but at the present moment one great want in connection with large distributions of alternating currents was an arrangement of main fuses which would not interrupt the circuit, but if the main current went above a certain value would put impedance into the circuit gradually but quickly, and then take it out again as required, but never allowing the main circuit to be broken. The great difficulty at present was that it *did* become broken, and a great rise of pressure took place, with disastrous results to the insulation. The question of pressure was one to which Prof. Forbes and his colleagues had doubtless given very serious consideration before deciding to adopt 20,000 volts. The difficulty which might be encountered with the high pressure was not the difficulty of working with the stock pressure of 20,000 volts, but the tremendous arcs which might be produced if they were started between the conductors. Prof. Forbes did not tell them, he believed, how far apart those cables were going to be in the conduits. He described a conduit in which copper strip was to be used as the conductor, but did not mention what distance they were to be apart. That was a very important matter. It might be impossible under some circumstances to prevent such rises of pressure that an arc would start, and what would be the state of affairs with naked conductors in those conduits if they were only, say, a foot apart? The question was sometimes asked, what is the best frequency to work at? It was very much like asking, what is the best speed to walk at? It depended upon where you were going and what you wanted to do. Continental engineers had not been at work at the matter at haphazard when they adopted a frequency of between 40 and 50. Our adoption of 80 to 100 was necessitated by the circumstances under which we had to start alternate-current working; and the same in America. But there was no doubt, he thought, about the wisdom of selecting this low frequency at Niagara, where the utilization of power by motors was an important matter, and there were enormous advantages to be gained by the reduction of these capacity effects and other effects of the same kind by the employment of a reduced frequency.



Dr. Fleming's Cable Connections.

Mr. W. M. Mordey said they were called upon to discuss a Paper on a subject of world-wide importance, and he believed a sense of responsibility would be felt by all speakers. What made the Paper so interesting was that Prof. Forbes not merely described the scheme and the works, but went pretty fully into reasons and principles. It was a very important matter that after so much work had been done on alternate-current distribution of all sorts that Prof. Forbes should come there and throw the gauntlet down to the whole industry on two or three points of primary importance in connection with distribution. Those of them, for instance, who had been working at comparatively high periods had to justify their continued existence and to prove that Prof. Forbes was wrong. Prof. Forbes stated in the Paper that "it is a matter of common knowledge that parallel working is assisted by lowering the frequency." With all respect, he (Mr. Mordey) would deny that. He thought there was no evidence whatever to show, with any good plant now running, that lowering the frequency had any connection with parallel working. If there was no difficulty whatever in working at 100 periods there could be no improvement in working at a lower rate. It might be that, with certain types of machines, there were advantages in working at lower rates, but he believed that a machine that was incapable of working at 100 periods would work worse at 16 or 40 periods than a machine that would work at 100 periods successfully. The only definite argument Prof. Forbes put forward was a letter from Messrs. Ganz, who had written him "that their reason in adopting the frequency of 42 periods per second was that it is the lowest frequency that is available with arc lights so as not to produce any serious flickering, and their desire was to lower the frequency as far as practicable in order to ensure parallel working." Now, Messrs. Ganz were very important people; they had large experience all over the Continent, but it was very necessary to examine and sift statements of this sort, and not to accept them as facts. He thought they ought to ask if Messrs. Ganz had not been a little forgetful in making such a statement as that. In his Paper on alternate-current working in 1889 he made a similar statement; he quoted a letter by Mr. Zipernowski to *The Electrician* of May 10, 1889, stating that their low periodicity was "chosen on principle," "that we by this means are enabled to couple our dynamos in parallel is not a secondary result, but just the end we are aiming at." His (Mr. Mordey's) surprise was, therefore, very great when during the discussion Mr. Zipernowski wrote: "We state that we have not reduced the periodicity because of the coupling in parallel," and added that they had always kept to 85 alternations with only slight variations. He happened to know that this last statement was correct. For a considerable time before parallel working Messrs. Ganz had been making alternators of 42 periods per second; when parallel working was recognized to be a necessity they made experiments and adhered to 42 periods, and gave out that they adopted it because it gave the best results in parallel working. He was not aware of any other support than that of Messrs. Ganz to Prof. Forbes's statement, and these words taken from Mr. Zipernowski's own writing showed that his last published statement contradicted his first, and acknowledged that they had made these machines for low periods for years before parallel working was thought of. The question of artificial loading in putting machines on to mains in parallel had also been dealt with by Prof. Forbes, and had been approved very strongly by Dr. Fleming. Now, that was an old, primitive, and he thought an obsolete method. He explained a plan got out some years ago by Mr. Raworth and himself, and published in his Paper "On Testing and Working Alternators," by which the regulation of each alternator was entirely controlled by controlling the steam supplied to its engine. There was another question affecting the periodicity to which Prof. Forbes referred as probably the most important. He said: I am not sure that it ought not to be said that the greatest advantage of low frequency is in connection with the conductors used for transmission, and in the parts of the apparatus that require high insulation." Then he referred to what was strongly pointed out by Lord Kelvin, and which was found out independently by those wonderful experiments of Prof. Hughes's, namely, the surface effects in conductors at high frequency, the tendency of the current to seek the outside of conductors. That was, no doubt, in low tension alternate-current distribution, an extremely important matter. But in the case of high pressures and long distance transmission he did not think those Hughes effects, as he would call them, were by any means serious, even for the large powers Prof. Forbes proposed. In 1889 he gave a table of the virtual resistances of conductors, based on Lord Kelvin's figures. In the Niagara scheme at 20,000 volts the full current on one of the machines, with 2,000,000 watts was only 100 amperes. Prof. Forbes selected 350 amperes to the square inch as a suitable density; he thought a larger density would be more economical unless their power was going to be very costly. But taking that density from his table of Lord Kelvin's results he found that at 100 periods per second, or six times as high as Prof. Forbes intended to use his conductor, there was scarcely any Hughes effect at all. Was it worth while going down to 16 or 25 periods per second in order to get this gain? Still, keeping to the subject of low periodicity, they came to the question of transformers. He believed it was impossible by any amount of money, or space, or time, or thought, to make a transformer anything like as good at a low period as at a reasonably high one. It was not a question of design or of money. The ordinary idea that they could design a transformor to be equally good under any given set of conditions, so far as periodicity was concerned, was an entire mistake; it was not possible. If they took a transformer made for 16 periods or 40 periods, and ran it at a higher periodicity it would give a very much better result. Prof. Forbes said that by using this low periodicity he had a gain of 3 per cent. more power at his disposal at the other end, and that the transformer only cost about 50 per cent. more. But what did that mean? Prof. Forbes said a transformer would give 132 units instead of 100 if they doubled the frequency, and if the frequency was quadrupled they would get 174 instead of 100. Suppose he took it at double the output, the hysteresis and $C^2 R$ losses remained the same, therefore the proportion of the losses had doubled. He had gone down much further than he need have done. He had a triple transformation, first up from his dynamo to his mains, then from his mains down to the 2,000 volt transformers, and then down to 100 volts probably for his motors, for they were going to be worked at low voltages and with transformers. Therefore, there was a triple transformation, and at the very least a sixfold loss. What did he gain? The author supposed that he got a motor that had 3 per cent. more efficiency than if he used a high periodicity one—a supposition that had no sufficient basis. One thing he approved of, and that was the transforming up from the generator. That was very much better than attempting to generate at 20,000 volts. He did not see why they should transform up from 2,000 volts to 20,000; 2,000 was not so safe as 500 volts, and it was just as easy and cheap to transform from 500 to 20,000 as from 2,000 to 20,000. He would pass over what he had intended to say about the commutation of current, but would just say this: Prof. Forbes had, by this low periodicity, cut himself off from the possibility of using the alternate current directly. He had cut himself off from using current directly in any way except for power; he must always transform up to a higher periodicity if he was going to use his power for lighting.

LEGAL NOTES.

THE SHIPMAN DECISION IN THE "NOVAK" GAS LAMP CASE.

United States Circuit Court for the District of Connecticut. Edison Electric Light Company and Edison General Electric Company *vs.* The Waring Electric Company, *et al.*

SHIPMAN, *C. J.*—This is a motion for the preliminary injunction against the alleged infringement of the second claim of letters patent, commonly called the incandescent lamp or the filament patent No. 223,898, dated January 27, 1880, to Thomas A. Edison.

The patent has been directly and indirectly, the subject of exhaustive investigation, before the Courts of this country, and was carefully examined by the United States Circuit Court of Appeals for this Circuit in the case of the Edison Electric Light Company against the United States Electric Lighting Company. In the opinion of the Court in that case, Judge Lacombe clearly states the history and nature of the invention, which consisted, in general, in substituting carbon "reduced in size to the filamentary form and placed in a nearly perfect vacuum" for illuminants which had previously been the subject of experiments, a change of material "which involved a reorganization of the lamp" and "presented the complete combination of elements, which for the first time in the art produced a practical electric light."

The second claim is thus paraphrased by Judge Lacombe: "The combination of carbon filamentary or thread-like in size and properly carbonized, used as an illuminant in an incandescent electric lamp in a receiver made entirely of glass and conductors passing through the glass, and from which receivers the air is exhausted to such an extent that disintegration of the carbon due to the air washing action of surrounding gases or to any other cause is so far reduced as to leave the carbon practically stable."

The defendants' lamp called the Waring lamp, is the Edison lamp, with the alleged exception that in the receiver, a nearly perfect vacuum has not been created by exhaustion of the air, but that into the partially exhausted receiver a portion of bromine gas has been introduced. This introduction of bromine and the consequent lessening of the vacuum, it is claimed, produced a marked improvement in the stability of the carbon and in the diminution of the blackening of the glass of the lamp.

This improved construction is protected by letters patent to John Waring, No. 497,038, dated May 9, 1893. The specification says that the atmospheric air may be partially withdrawn by means of an air pump, and the gas is then admitted. "This gas admitted to the globes and diluted by the air remaining in them is then partially withdrawn and more gas allowed to enter, this process being repeated until the extent to which the desired gas is diluted with foreign gases has become practically infinitesimal. If preferred, the atmospheric air may be at first exhausted as nearly as possible, and the desired gas then admitted around the carbon. The amount of gas to be admitted will in practice vary with the size of the inclosing chamber, with the nature of the gas and probably also with the nature of the other elements of the lamp." This vague description of the ultimate character of the vacuum and of the amount of "desired" gas, which was to be admitted, furnished inadequate data by which to ascertain with precision the extent of the departure from the Edison lamp. The question naturally arises, how much desired gas is admitted, after the atmospheric air has been exhausted "as nearly as possible." The defendants' affidavits state the successive steps which are taken in practice and the resultant vacuum is given in a number of the affidavits with adequate accuracy.

Prof. Appleton gives the essential features of the process, as he saw it in the ordinary manufacture of the lamp, as follows: Atmospheric air was pumped from the bulb by a mechanical pump, not by a mercury pump. Bromine vapor was allowed to fill the bulb, so that the orange red color of bromine was visible therein. Then followed pumping by a mechanical pump by which "bromine vapor and air are to a large degree removed." An ample amount of bromine vapor is again allowed to fill the bulb. A third mechanical pumping follows, by which, "residual air and bromine vapor are largely removed, but some bromine vapor remains."

The lamp is sealed by fusing the glass opening. The general conclusions, taken by themselves, of Prof. Appleton and also of

Prof. Carmichael, both competent analytical chemists, whose affidavits are introduced by the defendants, would far from satisfy the mind that a material departure from the exhaustion which was the result of the Edison method of manufacture, had been sought in the Waring lamp. For example, Prof. Appleton says: "My conclusions, therefore, are that the Waring Electric Company is undoubtedly introducing bromine in their lamps in the process of manufacture, that the bromine remains in them after their entry in the market; in a given bulb, the quantity is small, but it is perfectly recognizable by the chemist and it cannot, in an electric lamp, be fairly called unworthy of consideration."

Prof Carmichael says: "The vacuum, as deduced from the experiment cited, is considerably less perfect than that of the Edison lamp. By the ordinary factory tests of observing the duration of the vibration of the carbonized filement, the Novak (Waring) lamps as supplied to me, appeared to be less perfectly exhausted than the Edison lamps, as I have ordinarily observed them in use."

Other experts upon each side of the controversy are, however, able to state with more mathematical accuracy, the exact nature of the vacuum, and they do not essentially differ in their conclusions.

The affidavit of Mr. Howell, in behalf of the complainant, after saying that all lamps exhausted to a high vacuum have residual gases remaining in them, which are "not common air but are probably a mixture of gases in which hydrogen predominates," states as follows:

"The vacuum produced in practice in the Edison lamp is about $\frac{1}{30000}$ of an atmosphere: that is, 29,999 out of 30.000 units of atmosphere are removed from the globe. Or, in other words, if we assume the height of a mercury column at atmospheric pressure to be 30 inches, such a column connected to one of these lamp globes will be depressed $\frac{1}{1000}$ of an inch, due to the pressure of the residual gas within the globe. A very much lower vacuum or high pressure than this, however, can be used in practice without destroying the commercial character of the lamp, even when no special gas is introduced into the globe. A pressure which will lower the mercury column $\frac{1}{100}$ of an inch, that is, a vacuum of $\frac{1}{3000}$ of an atmosphere would, I believe, be sufficient for commercial purposes without the use of any of the supposedly inert gases, although a higher vacuum is more desirable."

The results of Mr. Howell's tests are as follows:

"The Waring lamps contain a gas pressure which may be as high as $\frac{1}{30}$ of an inch in the case of the 16 c. p. and 25 c. p. lamps, and which runs from that pressure down to $\frac{1}{100}$ of an inch in the case of the 32 c. p. lamps and 50 c. p. lamps, * * *.

In considering the effect of even so high a pressure as $\frac{1}{30}$ of an inch, it should be borne in mind that this means a vacuum of $\frac{1}{600}$ of an atmosphere, involving the removal of 599 out of 600 parts of the air or other gases within the globe."

Mr. Thomas B. Stillman for the complainant, found that each one of the 16 c. p. Waring lamps which he tested contained a pressure of $\frac{1}{666}$ of an atmosphere, or a vacunm in which 665 out of 666 units of gas are removed.

Turning now to affidavits of the disinterested witnesses for the defendant: Professors Wright and Anthony devote themseves substantially to a statement of their opinions in regard to the improved character of the Waring lamp over that of its Edison predecessor by reason of the introduction of bromine gas which they think preserves the transparency of the walls of the lamp and the stability of the carbon. While the question of the extent of an alleged improvement upon an existing patented combination may become incidentally important in ascertaining the character of the departure from the peculiarities of the invention which were described in and protected by the patent, it is obvious that the first and vital question is, were all the elements of the patented combination used in the second and improved invention in the manner and to produce the results described in the antecedent patent. Without, therefore, attempting to ascertain the correctness of Professor Anthony's conclusions that the introduction of bromine into the chamber of an incandescent lamp is a new step in the art where results "are of the utmost importance," I shall confine myself to a consideration of the question, whether before he took the step he made use of the Edison entire combination, and whether the alleged improvement is an addition to, and not a substitute for, one of Edison's described elements.

The defendant's affidavits, which are of importance in this connection, are those of Professors Carmichael and Robb and Mr. Charles A. Stone. Professor Carmichael says that the Waring lamp contains residual gases which occupy about $\frac{1}{2000}$ of the whole volume of the lamp and the bromine vapor about $\frac{11}{10000}$ and together $\frac{1}{625}$. Mr. Stone places the exhaustion of the Waring lamp to between $\frac{1}{600}$ and $\frac{1}{1000}$ of an atmosphere.

The conclusion of Professor Robb, who, it is proper to say, has given more attention to this subject than either of the other experts for the defendant, is that the bromine gas in the Waring 16 or 25 c. p. lamp is under a pressure, when the lamp is heated, of about $\frac{1}{600}$ of an atmosphere. There is, therefore, no important disagreement between the experts on either side in regard to the vacuum in the lamps of those respective powers. The estimates vary from $\frac{1}{600}$ to $\frac{1}{666}$ of an atmosphere.

It must be observed that Mr. Howell's tests of 50 c. p. Waring lamps (not including those called Lot No. 1, which turned out to be vacuum lamps manufactured by the Perkins Company) showed a high vacuum. He thinks that the vacuum in the 50 and in the 32 c. p. Waring lamps exceeded that in those of lower power. The experiments of the defendants' experts has been limited to lamps of 16 and 25 c. p. and therefore I shall confine myself to the results which flowed from these experiments and which, of course, I assume to be true.

The defendants' legal position is authoratively stated in Seymour vs. Osborne, 11, Wall, 516, as follows:

"Inventors of a combination * * * * * * cannot suppress subsequent improvement which are substantially different, whether the new improvement consists in a new combination of the same ingredients or of a substitution of some newly discovered ingredient or of some old one performing some new function not known at the date of the letters patent as a proper substitute for the ingredient withdrawn from the combination constituting their invention." Their theory is that the instroduction of bromine gas into a globe only partially exhausted is a substitution of a newly discovered ingredient for the air exhaustion of the Edison patent.

What Waring puts into the receiver is not of prime importance, but the question to be solved is whether he exhausts the contents of the globe, whether air, residual gases, or newly introduced bromine gas to such an extent that when the glass is sealed, he has used that part of Edison's combination to such an extent that thereby the carbon is rendered practically stable. The mere introduction of gases into the receiver is not important, but if, before they had been introduced, Waring takes away the atmospheric air and the residual gases and, after the new addition has been introduced, he takes away the contents of the globe by exhaustion, so that a practical vacuum finally remains, not as high as Edison thought necessary, for the spongy and porous cotton thread which he carbonized, but a vacuum which renders practically stable a carbon, filamentary in size and of whatever hard and dense material it may be composed, then Waring has taken the combination of Edison, however much he may have improved it by the residual of bromine gas which Prof. Carmichael estimates to occupy $\frac{11}{10000}$ of the volume of the lamp.

To ascertain the effect of the exhaustion by the Waring method upon the stability of the carbon, it is necessary to look at the result of Prof. Robb's instructive experiments, which were as follows:

Four Perkins, 25 c. p. lamps and four Edison 16 c. p. lamps were taken to the Waring factory. Two Perkins lamps (Nos. 1 and 2) and two Edison lamps (Nos. 1 and 2) were left unaltered. The remaining lamps (Perkins Nos. 3 and 4 and Edison Nos. 3 and 4) were opened and partially exhausted and treated with bromine as if they were Waring lamps in the ordinary course of manufacture. The voltage required to raise the lamps to their normal c. p. was measured.

Perkins	lamps	No.	1	(original lamp)	gave	25	c. p.	at	47.7	volts.
“	“	“	2	(“ “)	“	25	“	“	48.0	“
“	“	“	3	(bromine “)	“	25	“	“	50.9	“
“	“	“	4	(“ “)	“	25	“	“	49.5	“
Edison	“	“	1	(original “)	“	16	“	“	56.3	“
“	“	“	2	(“ “)	“	16	“	“	54.0	“
“	“	“	3	(bromine “)	“	16	“	“	59 0	“
“	“	“	4	(“ “)	“	16	“	“	59.5	“

The four Perkins lamps were then run at 65 volts for 10 hours and 75 volts for four hours. The Edison lamps were run 8 hours at an average of 78 volts. The c. p. of the lamps was then measured at the same voltages as those at which the preceding remeasurements had been made, and it was found that:

Perkins	lamp	No.	1	(original lamp)	gave	13.6 c. p.
“	“	“	2	(“ “)	“	13.8 “
“	“	“	3	(bromine “)	“	23.0 “
“	“	“	4	(“ “)	“	Candle power could not be measured as filament broke a few minutes before run ended.
Edison	lamp	No.	1	(original lamp)	“	6.1 c. p.
“	“	“	2	(“ “)	“	4.4 “
“	“	“	3	(bromine “)	“	9.9 “
“	“	“	4	(“ “)	“	11.0 “

The second test was as follows:

"I took four lamps in the course of construction at the Waring Electric Company's factory and had them exhausted on the pump at the same time. Two of these lamps (Waring lamps Nos. 1 and 2) were filled with bromine and two (Waring lamps Nos. 3 and 4) with air, the degree of exhaustion being identical in all four lamps. The filaments in these lamps were intended for 16 c. p. lamps and the voltage at which the lamps would yield 16 c. p. was measured at the Physical laboratory of Trinity College, and it was found that:

Waring	lamp	No.	1	(Bromine lamp)	gave	16	c. p.	at	118.0	volts.
“	“	“	2	(“ “)	“	16	“	“	115.0	“
“	“	“	3	(Air “)	“	16	“	“	128.9	“
“	“	“	4	(“ “)	“	16	“	“	126.9	“

The lamps were then run at 115 volts for 20 hours. The candle power of the lamps was then remeasured at the same voltages as those at which the preceding measurements had been made, and it was found that:

Waring	lamp	No.	1	(Bromine lamp)	gave	16	c. p.
“	“	“	2	(“ “)	“	16	“
“	“	“	3	(Air “)	“	9.4	“
“	“	“	4	(“ “)	“	11.0	“

These and kindred tests satisfy Prof. Robb that the vacuum in the bromine lamps is so poor that if the vapor in the lamps had been air instead of bromine they would have been considered worthless.

In view of the present condition of incandescent lighting in this country, I have no doubt that an Edison lamp with the exhaustion which was given in the experiments would be considerd by the users of electric light as so far inferior to the ordinary standard of an Edison lamp as to be worthless, and would be discarded by those who were accustomed to the usual stability of an incandescent lamp. But the experiments show to my mind, when read in connection with the other affidavits of the defendants, that Waring intentionally used the principle of exhaustion to a generous degree and that the vacuum ingredient of Edison, was, to a large extent, employed and its benefits were partially enjoyed. Waring took the lamp which Edison gave us in 1880 and which was the first practical incandescent electric light and used the idea of exhaustion to a more limited extent than the original inventor thought was necessary; nevertheless, without the large exhaustion of the atmospheric air and the gases which Waring accomplished, his lamp would be a failure.

It will not be claimed that the inventor of an improvement upon a previously patented combination can use one of the patented elements in a dwarfed and incomplete way, but by its use receive the old resultant benefit, and escape the charge of infringement by reason of the low percentage of such use. The defendants' theory is that its use is so far unlike that of Edison that it can properly be said to be radically different. That theory is not supported in the Waring specification and it does not seem to me to be supported by the facts. The statement in the specification that the atmospheric air may be at first exhausted as nearly as possible and the desired gas then admitted is significant. Professors Appleton and Carmichael's affidavits show that the amount of gas which finally remains in the lamp globe is small.

The defendants claim that the Edison patent which was dated January 27, 1880, has expired by reason of the expiration of the British patent No. 4576 for the same invention antedated to November 10, 1879, but not sealed and the specification of which was not enrolled until after the United States patent in suit had been issued.

This question was recently examined by Judge Jenkins in the American Bell Telephone Company vs. Cushman, 57 Fed. Rep. 842, He refers to the various decisions upon the question and concludes that "the invention is not patented abroad before the actual sealing and issuance of the patent," and that the term "patented" as used in section 4887 of the Revised Statutes, does not mean the preliminary proceedings but the actual issuance of the patent under the seal of the Government speaking the exercise of sovereign will, investing the patentee with a grant of a monopoly. In this conclusion I entirely concur.

The motion is granted. The terms of the order are to be settled upon notice.

C. A. Seward, F. P. Fish and R. N. Dyer, for the complainants.
Chas. E. Perkins and W. E. Simonds, for the defendants.

Our New England editor writes :—

Another hearing was had before Judge Shipman on Saturday, January 13, when the Judge granted a stay of injunction pending an appeal to higher courts, under bonds of $10,000. The Judge entertained a grave doubt as to whether his opinion already rendered was a just one as it brought up a number of new features in the art of incandescent lamp making. The General Company offered to go under bonds themselves if the injunction were granted, but the court declined to accede to the proposition. It is understood that under this action of the court, the Waring Co. will have at least another month free from all trouble before the case can come up again. They were proceeding with the manufacture of the lamp as usual last week.

PROF. ROWLAND vs. THE CATARACT CONSTRUCTION CO.

Suit has been brought against the Cataract Construction Co., by Prof. Henry A. Rowland, of Baltimore, for $30,000, claimed as the value for services rendered in connection with the electric power transmission at Niagara. It appears that after the plans of the engineers of the Cataract Co., had been formulated they were submitted to Prof. Rowland for his opinion as to their feasibility and after a careful study he submitted an opinion embodying improvements differing widely in character from the methods and designs indicated in the original plans. For this opinion Prof. Rowland presented a bill of $10,000 to the company, which was considered excessive and which was only honored to the extent of $3,500. Hence the suit.

Prof. Rowland claims that practically all of his suggestions were adopted by the Cataract Co., and that by so doing they saved a large amount of money ; and hence he considers his charges no greater than the magnitude and importance of the work warranted him in making them.

The case was to have come up for hearing last week but was postponed owing to the crowded condition of the Court calendar. A number of eminent electrical engineers will appear on both sides and it is believed that some interesting details relating to the Niagara project will be brought out during the trial.

INJUNCTION AGAINST THE DE KHOTINSKY LAMP.

Circuit Court of the United States, District of Massachusetts. In Equity. No. 3,211. The Edison Electric Light Company, *et al.*, *vs.* Achilles de Khotinsky, *et al.*—Opinion of the Court (filed Jan. 9, 1894).

Colt, *J.*—The defendants do not disclose by their affidavits the kind or amount of vapor which is inserted in the glass bulb of their lamp. From all that appears therefore the defendant's lamp has the vacuum called for by the Edison patent, although it may contain in addition a small amount of some kind of gas or vapor.

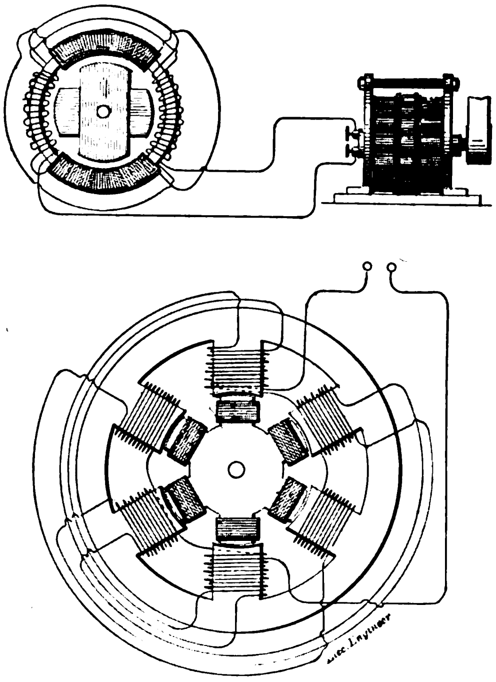
Under the circumstances it would be improper for the Court to enter further into the consideration of the questions sought to be raised by this motion.

As the proof stands, I am of opinion that the defendant's lamp contains all the elements set forth in the second claim of the Edison patent. *Motion granted.*

PATENT NOTES.

TESLA SINGLE CIRCUIT ALTERNATING MOTOR.

In a patent issued to Mr. Nikola Tesla, on Jan. 2, entitled "Electrical Transmission of Power," No. 311,915 originally filed May 15, 1888, that inventor describes a method of operating motors from a two-wire alternating circuit. The method employed is set forth in the two claims of the patent which we give below :



Tesla Single Circuit Alternating Motor.

1. The method of operating electro-magnetic motors having independent energizing circuits, as herein described, which consists in passing an alternating current through one of the energizing circuits and inducing by such current the current in the other energizing circuit of the motor, as set forth.
2. The method of operating electro-magnetic motors having independent energizing circuits as herein described, which consists in developing an alternating current in one of said energizing circuits and inducing thereby currents in the other energizing circuit or circuits, as herein set forth.

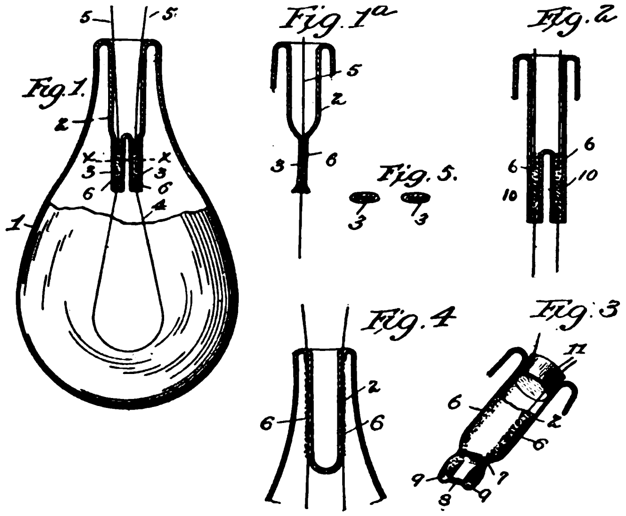
THE NEW BUCKEYE LAMP WITHOUT LEADING-IN WIRES.

Since the decision sustaining the Edison lamp patent was rendered, numerous forms of lamps have been produced embodying features claimed to be outside of that patent. The principal claim of the Edison patent it, will be remembered, is what is known as a "combination" claim, involving the elements of an all-glass receiver, a carbon filament, a vacuum and leading-in wires. A lamp, therefore, embodying all but one of these elements would not come under the claims of the patent and as a result we have lamps made with the glass in two parts, like the Westinghouse stopper lamp, or the Beacon with a composition stem through which the leading-in wires pass, etc.; while others again have been made with filaments claimed to contain no carbon.

In all these lamps, however, leading-in wires have been used; but even this element, it would seem, is capable of evasion or abolition as exemplified in the new Buckeye lamp, noted by us last week and just brought out by the Buckeye Electric Co., of Cleveland, Ohio. This new lamp is based on a patent issued to the late Edward Pollard, of Cambridge, Mass., entitled "Incandescent Electric Lamp," No. 485,478, issued March 2, 1892 from which we reproduce the accompanying illustrations. Fig. 1 shows a vertical section of a lamp and Figs. 1a the details of the stem holding the filament; while Fig. 5 is a section on the line *x x*.

The leading-in wires in this lamp are replaced by a conductor formed by depositing upon glass a line of silver or other metal in powdered form and then heating the glass sufficiently to cause the metal to adhere to it. The line of minute particles thus embedded in the surface of the glass forms a conductor for the electric current. In embodying this principle in a lamp, as shown in Fig. 1, the interior surface of the tubes 3 3 is coated with sizing, and upon this sizing there is sprinkled fine silver powder, after which the tubes are heated sufficiently to cause the particles of silver to adhere firmly to the glass, the sizing serving to hold the powder in position upon the glass until the glass is raised to the temperature necessary to cause the powder to adhere thereto. While the glass is hot the stem is pinched until its opposite walls come in contact and become welded together, Fig. 1a, thus forming a seal. The ends of the carbon filament are attached within the ends of the glass tubes by carbon paste. The conducting-wires 5 5 are connected by cold-pinching them within the tubes 3 3, having the wire in contact with the silver, as shown in Fig. 1. The silver particles thus united with the glass form a conducting connection between the conducting-wires and the carbon filament.

According to the inventor the best method of obtaining the silver in powdered form is to dissolve the silver in nitric acid and then suspend pieces of copper in the solution to cast down the silver in a very fine powder. The silver is then thoroughly washed and passed through a fine sieve. The sizing used to attach the powder to the glass is made by mixing together copaiba balsam (two parts) and fir balsam (one part.)



THE NEW BUCKEYE LAMP.

Figs. 2, 3 and 4 show various modifications of the method of applying the conducting powder to the stem. The process has since been further refined and perfected.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS—DR. LOUIS BELL ON POLYPHASE APPARATUS.

THE eighty-third meeting of the Institute promises to be very interesting. It will be held at headquarters, 12 West Thirty-first street, New York City, to-day, Wednesday, January 17, at 8 o'clock p. m.

A paper will be presented by Louis Bell, Ph. D., of Boston, on "Practical Properties of Polyphase Apparatus."

By direction of Council, the last report of the Committee on Units and Standards will be presented for discussion, in which is proposed the provisional adoption of the terms "gilbert," "weber," "oersted" and "gauss." The full report will be found on page 662 of the December Transactions.

The January issue of the Transactions will not be published until after the next meeting.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

MR. C. O. BAKER, JR., master of transportation, writes us as follows:

The Trunk Line Association have granted the rate of a fare and a third on the certificate plan to Washington and return during the period of the Convention, namely, February 27, 28, March 1. The various other passenger associations have the matter under advisement, and will, in all probability, render their decision in the near future.

MONTREAL ELECTRIC CLUB.

WE have received the constitution and bylaws of the Montreal Electric Club, whose useful object is to promote the knowledge of electrical science. It has members and associate members, with appropriate qualifications for each class.

PERSONAL.

MR. JOHN PRICE JACKSON is now in charge of the Department of Electrical Engineering at the Pennsylvania State College as Assistant Professor of Electrical Engineering.

MR. GEORGE E. BADGER has resigned his position at the Edison General Company's works, Schenectady, N. Y., and has left that city to assume the management of Mr. Edison's mining machinery interests in New Jersey. Mr. Badger has been prominently identified with the Edison factory, having been night general superintendent for several years.

WEMPLE-POPE.—The marriage is announced for January 23, at Elizabeth, N. J., of Miss Nellie Lowrey Pope, daughter of Mr. R. W. Pope, secretary of the American Institute of Electrical Engineers, to Mr. Horace Russ Wemple. Miss Pope has been of much service to the Institute in recent years, in assisting her father upon state occasions, and may well be looked upon as the "daughter of the regiment." All its members will wish for her a very happy and prosperous married life.

OBITUARY.

WILLIAM RICHARDSON.

MR. WILLIAM RICHARDSON, so long president of the Atlantic Avenue Railroad, Brooklyn, and who died of heart failure in that city on December 31, was born in Berkhampstead, England, on December 8, 1822. When twelve years of age he went with his father to Gambier, Ohio, where he obtained a position in a newspaper office. In 1840 he removed to Albany where he remained for twenty-five years interesting himself in city affairs and later joining the editorial staff of the Albany *Evening Journal*. At the outbreak of the war he was appointed a paymaster in the Army, and at its close became superintendent of the Dry Dock, East Broadway and Battery Railroad Company. Within a few weeks he became one of the directors and shortly afterward was elected president of the road, which office he resigned in 1867 and became sole lessee and proprietor of the Brooklyn and Jamaica Railroad Company. He served on the Brooklyn Board of Aldermen for two years—1870 and 72—and was a member of the first Republican State Committee. He was a Freemason, an Odd Fellow and a member of several other civic organizations and was prominently identified with the Baptist Church. Of late years, despite early prejudices against electric traction, he showed great interest in electric railways, and his death finds Brooklyn one of the foremost cities in the Union in the adoption of electricity on its street railways, the Richardson roads now being fully equipped.

No one will be more missed at the meetings of the American Street Railway Association than the white-haired, witty, incisive Deacon, with his strikingly English way of hanging on to a thing till he had found out or fought out all there was in it worthy a struggle. His son has long been the efficient secretary of the Association.

REPORTS OF COMPANIES.

REPORT OF THE STANDARD UNDERGROUND CABLE CO.

THE STANDARD UNDERGROUND CABLE COMPANY, Pittsburgh, have declared the usual quarterly dividend of 1½ per cent. During the year the company secured new orders amounting to $628,000. At the beginning of the year unfilled orders amounting to $100,000 remained on hand, which makes the approximate business for the year $725,000 gross. For the first 11 months of the year the net earnings amounted to $118,735, and it is estimated that with December's earnings the company will show net returns of at least $130,000, which is over 12 per cent. on the capital stock. The net earnings of 1892 were $93,000, showing an increase during 1893 of about $40,000. The company have most of their departments running day and night throughout the year, and begin the new year with enough orders on hand to run day and night until May 1.

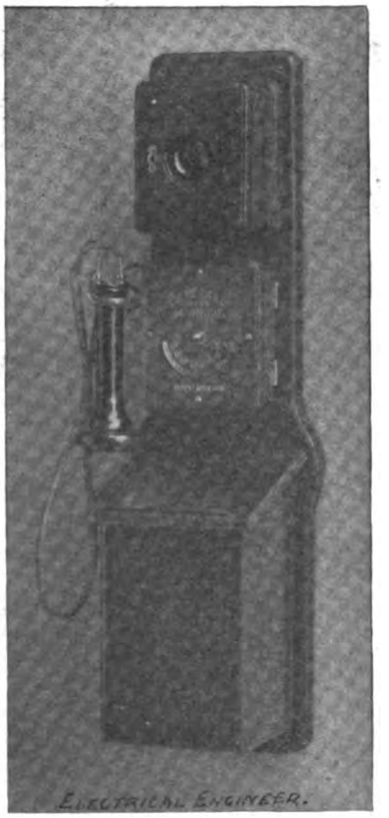
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE NESS AUTOMATIC WAREHOUSE TELEPHONE.

A NEW warehouse telephone has just been introduced by the well-known telephone and electrical manufacturing firm, T. W. Ness & Co., of Montreal. The special feature of this new instrument, which is the invention of Mr. T. W. Ness, and has been patented in Canada, the United States and other countries, is an automatic switch return by means of which the switch is brought back automatically to its normal point after conversation is finished. Those who are familiar with the old systems, in which connection is made by inserting a plug in a socket corresponding with the line desired, which plug requires to be withdrawn after through talking, but is constantly overlooked, or the old style of switch, which requires to be returned by hand to its normal point, will at once see, and appreciate the great value of this new and unique invention.

The style of instrument is shown in the accompanying engraving.



NESS AUTOMATIC WAREHOUSE TELEPHONE.

The automatic switch, receiver hook and bell, are combined in the centre box. This system is particularly suitable for connecting the different departments of factories, warehouses, offices, banks, colleges, etc. It will be observed that no central office for making the different connections is required; each instrument in a series has switchpoints corresponding or connecting with each of the other instruments. Thus any one telephone can call up any other, simply by turning the switch lever around to the point corresponding with the instrument desired, and at the same time ringing up, which is done by pressing the lever down upon the outer-ring, shown below the switchpoints; this causes the bell of the required instrument to ring. After conversation is finished, the hanging up of the receiver causes the switch lever to return automatically to its own point, thus leaving the telephone in position to be called up by any other instrument. When desired, the instruments can be so arranged that only certain ones in a series can call up certain others, instead of having the whole system interchangeable. In ringing up, only the bell of the instrument required sounds, so that none of the others is disturbed; and conversation is at the same time private. In a series of, say, eight instruments, 1 and 3, 2 and 4, 5 and 6, might converse at the same time without interfering with one another.

The firm of T. W. Ness & Co. have been manufacturing main line and warehouse telephones for a number of years. The large number of testimonial letters submitted from leading business houses, speaks well for the satisfaction their instruments are giving.

It is understood that the firm contemplate establishing a branch in this country for the manufacture of their various lines of telephones.

THE NEW NATIONAL ELECTRIC COMPANY.

The management of the new National Electric Co. of Eau Claire, Wis., comprises A. L. Ide, president; Peter Truax, vice president; F. P. Ide, secretary and W. A. Rust, treasurer. While adhering strictly to the National type of apparatus, the company proposes to introduce all improvements suggested or rendered necessary by the advance of the art. The various designs have been scrutinized and modified wherever desirable, and the factory equipment has been revised and enlarged, so as to turn out good work with increased facility. The selling department has been thoroughly reorganized. Messrs. F. W. Horne and John L. Martin, late of the Chicago office of the General Electric Co. have taken the general selling agency of National apparatus in the United States, with headquarters at 505 Home Insurance Building, Chicago. Local agencies are now being actively started all over the country. The alternating dynamos and transformers are in all sizes and are accompanied by fine station equipment and switchboard details. In direct current, there is a large line of bipolar dynamos and motors, and the multipolar units run up as high as 250 h. p.

It may be added that while the company is under Mr. A. L. Ide's able and vigorous management, it is, and will be kept, entirely distinct from the Ide Engine Co. of Springfield Ill. The National Electric Co. invite correspondence.

ELECTRIC APPLIANCE COMPANY.

THE ELECTRIC APPLIANCE COMPANY report great progress with the Packard transformer. Two orders of nearly one thousand lights capacity each is the record for the past week in addition to numerous smaller orders in the past few weeks aggregating over one thousand lights. Reports from customers show a very high efficiency coupled with close regulation and general satisfactory results.

THE ANSONIA ELECTRIC CO.'S OFFER.

AFTER careful consideration, the directors of the Ansonia Electric Co, have withdrawn their offer of 60 cents on the dollar, in long notes, the reason given being that the proposition was not generally availed of, and that the business in Chicago is now pretty badly disorganized. Another offer will be made, of lower amount, but probably on a cash basis.

IDEAL OIL FILTERS.

THE hard times of the past year seem to have benefitted at least one concern. The Purity Oil Filter Co. of Pittsburgh say they have found manufacturers willing to investigate appliances which, though involving some initial expense, were very economical in the long run; and to this fact they attribute the great number of recent sales. The circular of Pacific Coast testimonials issued by the Company speaks in highest terms of the Ideal oil filter. Not the least testimonial is the only eastern one in the lot, speaking of comparative tests, in which the "Ideal" was proven the superior.

THE CARD ELECTRIC MOTOR AND DYNAMO COMPANY.

THIS company has just moved into its new factory at the corner of Broadway and Hunt street, Cincinnati, Ohio. The building is one of the handsomest structures devoted to manufacturing in the United States; while the arrangement of general offices, especially with reference to all modern interior conveniences, etc., is simply ideal. There is no counter-shafting or belting used in connection with any machinery in the factory, each lathe, drill, etc., being run by its own motor. One of the front rooms is being fitted up as a show-room, in which may be seen the different types of apparatus manufactured by the Card Company. Messrs. Wilshire and Bullard are to be congratulated upon their new factory and upon the successful business which has made it possible.

MR. A. LANGSTAFF JOHNSTON C. E., E. E., has been awarded by the Franklin Institute the Edward Longstreth medal of merit for his safety disconnector for electric railway trolley circuits. The device has been described and illustrated in THE ELECTRICAL ENGINEER.

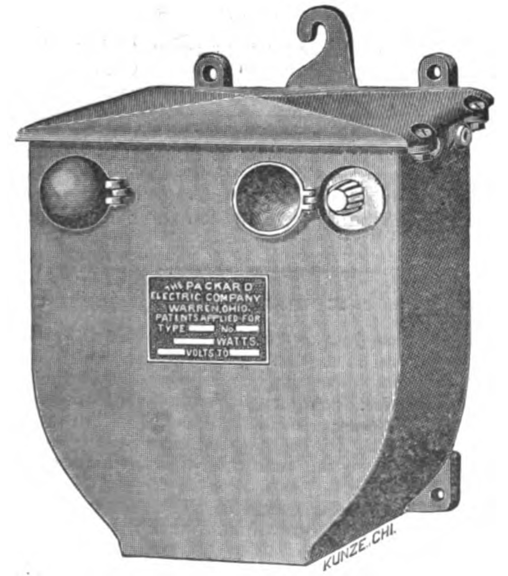
THE PACKARD TRANSFORMER.

The improvement of the past few years in transformer construction has probably been more marked than in any other class of electrical appliances. In the Packard transformer which is shown in the accompanying illustration, an attempt has been made to incorporate all of the improvements of the past few years in transformer construction, and at the same time to avoid the mistakes which have naturally been made in many cases in attempting to secure desirable but hitherto unattained results. The innovation of the oil transformer was one of the many attempted improvements and while it has its advantages there are also many objections to its use. Perhaps the most radical change has been in the construction of transformers with removable coils. While these have not been on the market for any great length of time it is becoming pretty clearly demonstrated that the convenience of being able to readily replace burned out coils is secured at altogether too great a sacrifice in efficiency and regulation. The tendency of improvement should be to perfect first construction, not to make provision for defects resulting from imperfect manufacture.

The effort of the manufacturers of the Packard transformer from the start has been to produce, not a transformer that can be easily repaired, but one that will not require such repairs, and hence in which the feature of cheap repairs ceases to be of any value. Severe tests covering this point have shown almost conclusively that the Packard transformer cannot be burned out under anywhere near normal conditions. The most desired results seem therefore to have been attained, providing of course that no sacrifice is made in other directions. It will be readily believed that no such sacrifice has been necessary as perfect insulation does not conflict in any way with high efficiency or perfect regulation, but is rather an assistance to it. Careful tests extending over a considerable period of time have demonstrated the attainment of the highest results as regards efficiency and regulation.

It will be observed that in mechanical construction the transformer is neat and compact, showing that careful consideration has been given to general detail. The fusing arrangement is most convenient and complete. Throwing back the two round covers or lids discloses two porcelain plugs which carry the transformer fuses. These can be withdrawn and re-fused or another plug inserted almost instantly without the use of any tools or the least danger to the operator.

In the construction of the coils the circular or ring form has been followed, and care has been taken to proportion the windings so that the best possible results will be secured. The point for which the great superiority of the Packard transformer is claimed however, is in the insulation of the tranformer coils. By a new system of insulating transformer windings the manufacturers have been able to secure the result hitherto unknown they believe, in the art, that is, a transformer that can not burn out under ordinary conditions. In the manufacture of the transformer every detail of the work is done only by experienced expert help and no expense is spared to make a perfect machine in every respect.



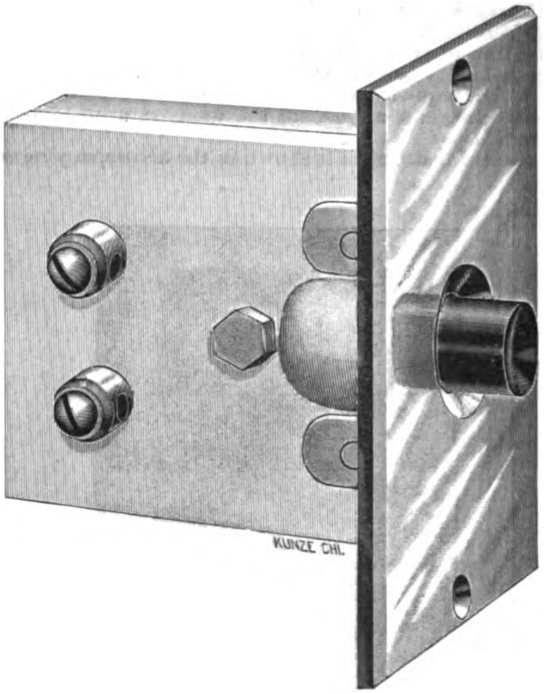
THE PACKARD TRANSFORMER.

The fact that the transformer, as its name indicates, is manufactured entirely under the personal supervision of Messrs. J. W. and W. D. Packard, the manufacturers of the celebrated Packard lamp, is a sufficient guarantee that nothing is spared to make every transformer that leaves the factory as perfect as money, long experience and skilled labor can make it.

The Electric Appliance Company of Chicago have taken the general western selling agency for the Packard transformer and are introducing it extensively in the west.

ELECTRIC APPLIANCE CO.'S NEW ELECTRIC LIGHT PUSH SWITCH.

A brief illustrated description of the mechanism of the new electric light push switch of the Electric Appliance Co. was given in our issue of Jany. 3. We are now able to present a cut showing the external appearance of the finished switch, and bringing out clearly the improved binding post connections, face plate, and general arrangement.



ELECTRIC APPLIANCE CO.'S NEW ELECTRIC LIGHT PUSH SWITCH.

The Electric Appliance Company report that a large number of inquiries resulted from our descriptive article on this specialty, and that the Standard single push switch seems to have already found favor with the trade.

THE OWNERSHIP OF THE WESTINGHOUSE MACHINE CO.

At Pittsburgh last week, says the *Iron Age*, George Westinghouse acquired absolute control of the Westinghouse Machine Company of that city by purchasing outright the entire stock held by Ralph Baggaley. The transaction involved 2000 shares and the price approximated $50 a share, or $100,000. The Westinghouse Machine Company was organized in Pittsburgh in 1881 with a capital of $500,000, $350,000 being common and $150,000 preferred stock. The par value of the shares is $50. The stock has seldom appeared on the market, for the reason that it is in the hands of a comparatively small number of shareholders. Dividends have been earned and declared recently without public notice, and at the annual meeting to be held shortly another dividend disbursement will be made. Mr. Westinghouse has always held a controlling interest in the company, and his holdings now amount to about nine-tenths of the 10,000 shares. Ralph Baggaley has been identified with the company since the inception in an official capacity as treasurer and general manager. No special reason was given by Mr. Baggaley for withdrawing from the company, except that his duties as president of the United States Glass Company made it necessary for him to give that company's affairs his undivided attention. It is believed that Mr. Baggaley will become a large owner of the shares of the glass company. The Westinghouse Machine Company are engaged in the manufacture of high class compound engines, several of which were used for driving the big generators used for lighting the buildings and grounds of the World's Fair. The company ship engines to all parts of the country, and their business is said to have increased to such an extent that the present manufacturing plant is running to its fullest capacity.

ACOUSTIC SYNCHRONIZER FOR ALTERNATING MACHINES.

WITH the extended employment of alternating current machines and with our modern ideas of central station practice, it is frequently desirable to run alternators, both single-phase and polyphase machines in parallel. Although alternators have not hitherto been run in parallel as a general thing on this side, the practice is not infrequent in Europe, where it has been made the subject of much study. The operation of alternators in parallel, however, is receiving more attention here, and a device to indicate in the most delicate, yet effective manner, the exact point of synchronism in speed and coincidence of phase of two alternators has become a necessity. This requirement is met by the acoustic synchronizer, which the General Electric Company has recently brought out, and which is shown in the accompanying engraving, Fig. 1. It consists merely of a cylindrical iron case with an aperture in the side, each end being closed by a flexible diaphragm, each of which has, opposite its centre the pole of an electromagnet.

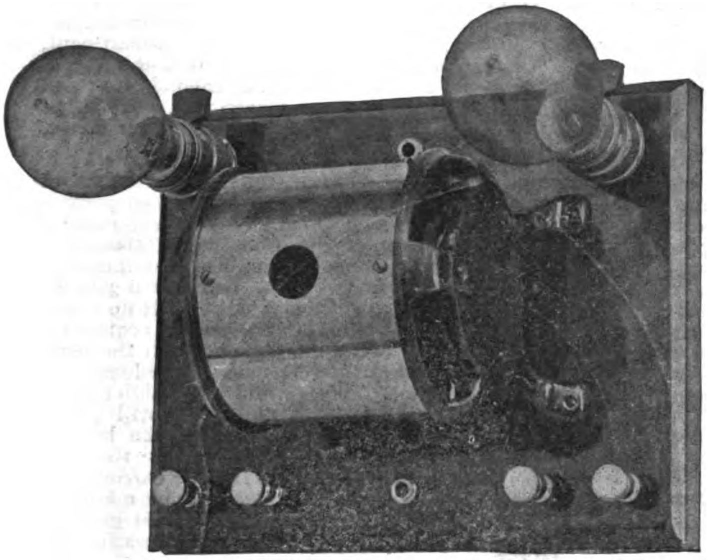


FIG. 1.—ACOUSTIC SYNCHRONIZER FOR ALTERNATING MACHINES.

In using this device one of the magnets is connected in circuit through a transformer with each of the machines to be run in synchronism. The current is then turned into the magnet coils, and the diaphragms emit a loud clear note. As the machines approach synchronism, the notes from the diaphragms approach closer in period and begin that loud, periodic sound, known in acoustics as beats. As the two machines more nearly approach synchronous speed, the beats grow slower and slower, until finally, the diaphragms fall into unison and each gives out the same low, clear note. At this moment, which is sharply marked, the switch connecting the two machines is thrown in. So sensitive and distinct is the indication of approach of synchronism, that it is possible to throw two machines together with hardly a quiver upon the ammeter in actual circuit. The superiority of this acoustic apparatus over the old phase-lamp device, cannot be disputed. It is much more sensitive, indicating distinctly the small differences from synchronism which the phase-lamp fails to detect.

The synchronizer was shown by the General Electric Company in its Power and Mining Department at the Chicago Exposition, where it attracted considerable attention, especially from foreign electricians. When it was shown to Prof. Von Helmholtz and its operation explained, he expressed himself delighted. It was a development in his own field of acoustics and showed how electricity and acoustics could work together for scientific benefit.

In a recent issue we described fully the three phase power transmission plant installed by the General Electric Company at Redlands, California. The switchboard there employed, Fig. 2, is fitted up with its different regulating and controlling apparatus, including the synchronizer, which the irreverent Californians have dubbed the "growler." Its operation is perfect, and it has not been known to fail in its functions in a single instance.

DALE MANUFACTURING CO.

THE DALE MANUFACTURING CO. (John H. Dale and L. J. O'Reilly), of 22 Cortlandt street, have issued a very neat, tasteful and practical catalogue of their electrical fixtures and supplies, including some novelties and specialties of great utility, such as the Dale separable cluster ball made for any number of lights, from 2 to 16. We commend this catalogue to the notice of the electrical trade and community.

THE WAGNER ELECTRIC MFG. COMPANY.

THIS company, St. Louis, Mo., is new enjoying a brisk trade in transformers of all sizes, and also has ready for the market a new alternating current motor in sizes from 1 to 10 h. p. Some of these motors have already been placed and are giving good satisfaction. The Wagner Electric Mfg. Company is glad to notice a distinct change for the better in the general business situation and is prepared to handle all orders promptly.

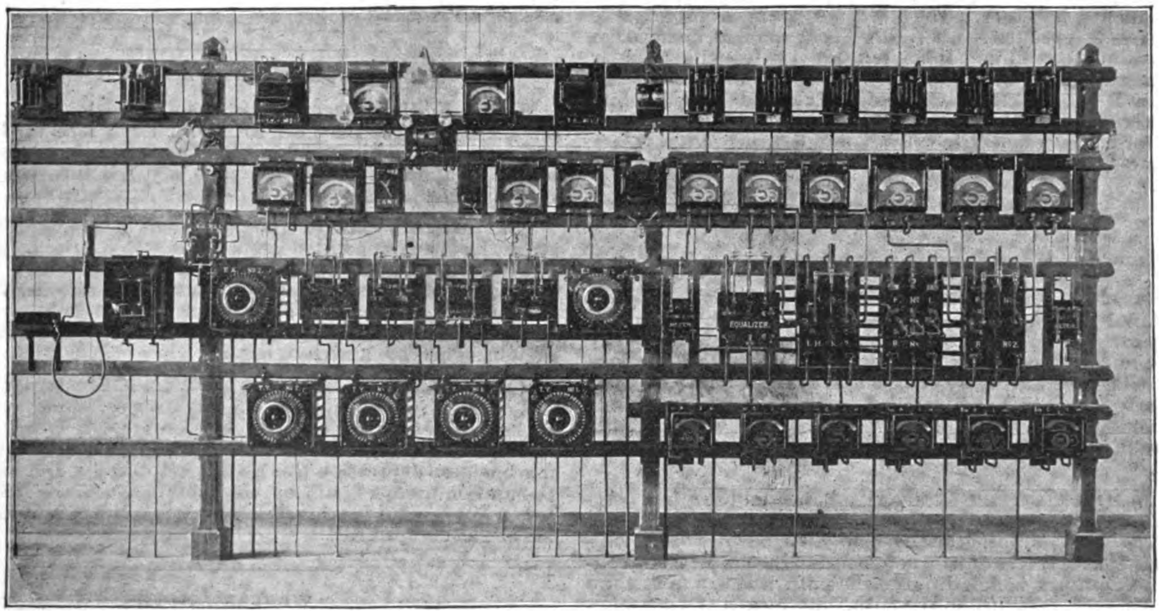

FIG. 2.—SWITCHBOARD OF THE 3-PHASE POWER TRANSMISSION PLANT AT REDLANDS, CAL.

KEOKUK, IA.—Judge Bank of the Superior Court, in Keokuk, Iowa, has appointed H. C. Reiner receiver of the Gate City Electric Street Railway on the application of the Central Trust Company of New York. The trust company holds first mortgage bonds for $850,000, on which the railway company defaulted interest.

"M.-V." AMMETERS AND VOLTMETERS.

Queen & Co., Incorporated, Philadelphia, have some very good commercial ammeters and voltmeters in the "Magnetic Vane" type which they have manufactured in large quantities for several years. These instruments are designed for light and power plants and when placed on a switchboard will indicate current or potential all day long. They are mounted in handsome cases, to present an attractive exterior, and are dust proof and also weatherproof, at least as much so as is possible with first class switchboard instruments. Interested persons can secure a copy of descriptive circular No. 420 by addressing the makers.

THE STEEL MOTOR COMPANY.

The Steel Motor Company, of Cleveland, Ohio, are in a most prosperous condition, and report that they are having all they can do to keep up with their orders. At present they are busily engaged in getting out 20 street railway equipments for use in Cleveland, and 8 for Allentown, Pa.; they have also started work on 100 controllers, 30 of which are nearly finished. The president of the Steel Motor Company is Mr. A. L. Johnson; vice-president and general manager, Mr. Samuel Harris, who is well known as being one of the pioneer electric street railway men of this country.

GOODRICH HARD RUBBER COMPANY.

A couple of very amusing pamphlets have been issued by the Goodrich Hard Rubber Company, of Akron, O., illustrative and descriptive of their electrical and other specialties. It is understood that the Goodrich Company supply wholesale all the best jokes and sketches that appear in *Judge*, *Puck* and *Life*, but that, as here shown, they reserve their choicest wit and humor for their own productions. Bill Nye, Mark Twain and Barrie are on their staff, and edit each other's work, so that only the very funniest things are allowed to see the light. The company ship each of their jokes done up in their tape, or quantities in a hard rubber case. All their goods are warranted the best and entirely free from hard cases.

J. W. PARKER & CO.

Philadelphia has proved too small for the energies of J. W. Parker & Co., agents of the Ball Engine Co., and they have now assumed charge also of the business of that company in New York city and its territory. They will organize a progressive and aggressive department with a New York man at its head, in nowise subordinate to Philadelphia, but both offices will be under the direct management of Mr. J. W. Parker. The business will be known as J. W. Parker & Co., New York and Philadelphia, general eastern agents for the Ball Engine Co., and contractors in general for complete electric railway and lighting steam power plants. No change will be made in the location of the offices in either city.

NEW ENGLAND NOTES.

The Eastern Electric Cable Company, of Boston, have recently declared their quarterly dividend of 2 per cent. Though not so busy as a month ago this company are still doing a very large trade, and are just entering into a number of new buildings which Mr. Clark has recently completed in the vicinity of their present quarters. They have installed a new Fitchburg engine of about 150 horse power, and will now be better situated than ever to take care of all kinds of wires and cables from the smallest to the largest.

The W. S. Hill Electric Company, of Boston, have just completed a novel device for electrically extracting from wood or rag pulp, used in the manufacture of paper, by a series of moving electro-magnets, all traces of iron contained in the pulp. The magnets have long prongs which dip into the pulp, and are in electric circuit so long as they are in the pulp. By means of a sprocket chain the magnets are drawn through the pulp, then elevated to a higher level, where they deposit their pickings of iron dust in a receiving tray, the circuit being broken when the magnets are in the proper position. A jet of water also assists in washing the magnets clean, ready for their next immersion in the pulp. The device is extremely ingenious and yet perfectly simple and practicable, and has proved a wonderful success. Paper manufacturers have experienced great difficulty in the past, on account of the iron contained in paper, and this device ought to eliminate all such trouble in the future. Already a number of important paper manufacturers have seen the working of the machine, and are well pleased with it, and it is almost beyond doubt that the Hill Company will have all they can do for some time to fill orders.

The Simplex Electrical Company of Boston, have recently given up their elegant suite of rooms at 620 Atlantic Avenue, and removed to even more convenient quarters at 75 to 81 Cornhill, Boston. For some time Mr. Mason, the manager of the company, has felt the inconvenience of being so far away from the centre of the city, and has now taken a step by which he will be able to handle their large business with much greater despatch and ease.

Mr. Edward D. Floyd, who has for the past seven years been connected with the Thomson-Houston Electric Company and the General Electric Company, recently in the purchasing department, has resigned his position, and associated himself with the Abbott Wheelock Company of Boston, who are large dealers in iron and steel. Mr. Floyd will be in the selling department, and will be glad to see his numerous friends hereafter at 35, Oliver street, Boston.

The Taunton Locomotive Manufacturing Company of Taunton, Mass., have recently had the right transferred to them to sell and manufacture the goods which have been supplied for years by the Wainwright Manufacturing Company of Massachusetts. For four years the Taunton Company has manufactured all the heaters, condensers, expansion joints, corrugated gaskets, etc., which the Wainright Company have sold, but will now take up also the selling as well. They are thus thoroughly acquainted with the various requirements of customers, and with the technical and engineering features of the business. The long business experience of the Taunton Company and their high reputation are guarantees that the appliances which they will manufacture under the Wainwright patents will be of the highest class, and their excellent facilities at Taunton assure that any business given them will be promptly and skillfully carried out. The various heaters, condensers, joints, etc., will be manufactured in future according to the lists and specifications given in the Wainwright Company's latest catalogue, and prices and discounts will remain the same.

The present agents will continue the sale of the goods on behalf of the Taunton Company and will be glad to furnish any desired quotations. The Wainwright heaters, condensers and other specialties have been very favorably known for years, and are in successful operation in hundreds of central stations for electric light railway and power purposes, as well as in many isolated plants, and will doubtless find even a larger share of patronage under the new management. The Taunton Company have a very large and fully equipped factory, full of the most recent labor saving tools and appliances, and are well equipped for this class of work. Besides the Wainwright specialties the Taunton Company are building a large number of snow ploughs and other devices for electric railroads, and will make an active bid for a share of the engineering work connected with electric development of lighting and power stations.

NEW YORK NOTES.

Mr. E. E. Higgins, expert in street railway values and economies, has removed his office to 26 Cortlandt street. His work is one of peculiar delicacy and difficulty, but is already beginning to be highly appreciated by those who buy, sell and promote electric railway enterprises.

Mr. W. A. Vail, of the Electrical Exchange, 136 Liberty street, has been appointed agent to represent the La Roche Company and apparatus in New York and New Jersey. It is an admirable selection, and though the times are dull, Mr. Vail will not be slow to "seal his contract" with a good order. His energy and popularity are strong factors making for his success, and he now has good apparatus to handle.

Clayton Air Compressor Works.—Working full time and full capacity, and behind on their deliveries, is the gratifying report furnished by the Clayton Air Compressor Works of 43 Dey street, New York, as to their shops in Brooklyn. In the prevailing business depression this speaks volumes for the excellence of the air compressors built by this company. They have recently taken out several patents on a new triple compound high-pressure air or gas compressor.

WESTERN NOTES.

The Brush Electric Co. have issued a most interesting and attractive pamphlet on their exhibit at the World's Fair. It embodies articles and notes descriptive of their large and artistic display, made under the direction of Mr. I. R. Prentiss, and is adorned with many cuts from various sources.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XVII. JANUARY 24, 1894. No. 299.

THE ELECTRO-MAGNET; or JOSEPH HENRY'S PLACE IN THE HISTORY OF THE ELECTRO-MAGNETIC TELEGRAPH.—III.

BY

Mary A. Henry

HENRY used his coil not only in the instruments for experiment, described in his communication to the Albany Institute. He remarks, in a subsequent communication to *Silliman's Journal*; "Several applications of the coil, besides those described in that paper, were made in order to increase the size of electro-magnetic apparatus, and to diminish the necessary galvanic power. The most interesting of these was its application to a development of magnetism in soft iron, much more extensive than to my knowledge had been previously effected by a small galvanic element."[1] This "development of magnetism in soft iron," was the development of the electro-magnet which was to render the lagging force of Volta's battery sufficient for the telegraph.

Before we see how this was accomplished, let us pause for a moment and consider what are the two foundation elements of the telegraph, as it now exists, a thing accomplished. These are the magnet, and the battery with its long conducting wire; these form the magic circuit which in fact constitutes the telegraph. There may be innumerable ways of opening and closing the circuit at one end, and of receiving or recording the message at the other; they are only changeable accessories, which may vary in every country and period. It is the combination of magnet and battery, which gives the power to produce electro-mechanical effects at a distance and *he who brought these two in harmonious accord, so that the one responds to the influence of the other at any distance, is the real father of the telegraph.* Very earnestly would we now ask our readers to remember exactly the state of things when Henry took up this important matter. The battery was in existence, and in its circuit Sturgeon had placed his magnet; yet still the telegraph was an impossibility, pronounced so by eminent men. The electric force diminished with the lengthening of the conducting wire; and repeated experiments only tended to show the impracticability of the scheme. The telegraph is an impossibility on account of the failure of the electric current; such was the conclusion of men of science in 1825 and nothing had come to change this opinion in the three years which had followed.

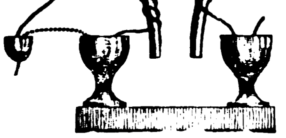

Fig. 1.—Sturgeon's Magnet.

We well remember, when approaching the great city of the past, the thrill with which we heard the cry, ringing out on the night air, "Il trano per Roma." It seems, in view of the long deferred hope of the world, now about to be realized, some such thrill might be felt as we see Henry taking up the feeble electro-magnet, destined under his hands to grow into the instrument which was at last to render the telegraph possible. Let us look again at Sturgeon's magnet, Fig. 1. According to Sturgeon's own description of it, in Nov. 1825, it consisted of a small bar of iron, bent into the form of a horse shoe, having a copper wire wound loosely around it in eighteen turns, with the ends of the wire dipping into mercury cups, the latter connected with the respective poles of a galvanic battery. Under the influence of a battery of *one hundred and thirty square inches of zinc surface, the magnet was capable of sustaining nine pounds.* Up to the year 1828, when Henry began his researches in regard to it, no improvement had been made in the instrument since Sturgeon's time; and if we consider the very large battery required to lift only nine pounds, we can understand the infant it was in strength and—while of undisputed value as a step in the progress of scientific investigation—how utterly unfitted it was for any actual service in either science or the arts.

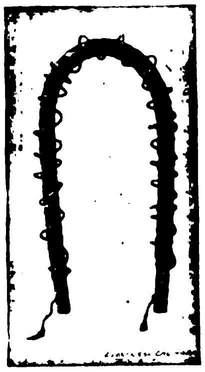

Fig. 2.—Henry's Reproduction of Sturgeon's Magnet.

Henry's first acquaintance with the magnet was in New York, where he had seen it exhibited in some lectures given by Professor Dana. His first step was to reproduce it; we give a picture of the little instrument he made, preserved in Princeton as a relic, Fig. 2. While his hands were busy making it, his thoughts were much upon the theory Ampere had deduced from his brilliant experiments, viz.: that magnetism is produced by electricity, passing around in the magnet like rings at right angles to its length. According to this theory, Henry thought: To make a magnet is to produce these currents in it; and to make a magnet by means of a voltaic current is to lead this current around the iron core of the magnet, as nearly as possible at right angles to its length. Was this condition fulfilled in Sturgeon's magnet? The spirals of the wire were wide apart; they had to be so, otherwise the current would have leapt from one to the other and not have run its desired course through the length of the wire. The current was conducted, not at right angles, but like a corkscrew around the iron bar. What was the first thing Henry did? A simple thing it would seem, but most important. He *insulated the wire*, wound it with silk. "It occurred to me," he said, "that a much nearer approach to Ampere's theory could be attained by insulating the wire conductor and covering the whole surface of the iron with a series of coils in close contact." Following this idea Henry made a number of small magnets closely wound with silk covered wire, to exhibit to the Institute: we give his description of one of them. Its lifting power is not stated, but it was much greater than that of Sturgeon's.

"A round piece of iron about ¼ of an inch in diameter was bent in the usual form of a horse-shoe, and instead of loosely coiling around it a few feet of wire, as is usually described, it was tightly wound with 35 feet of wire covered with silk, so as to form about 400 turns; a pair of small galvanic plates, which could be dipped into a tumbler of diluted acid, were soldered to the ends of the wire, and the whole mounted on a stand. With these small plates, the horse-shoe became much more powerfully magnetic than another of the same size and wound in the usual manner, with the application of a battery composed of 28 plates of copper and zinc, each eight inches square."

---

[1] "Scientific Writings of Joseph Henry." Vol, 1, page 88. Smithsonian Institution, 1886.

This magnet "of the same size and wound in the usual manner" is Henry's copy of the Sturgeon magnet with its loose spiral. Henry must have been pleased with the success of his first steps in the improvement of the instrument. Think of the difference. To make this horse-shoe a magnet only two small plates, easily dipped into a tumbler of acidulated water, were needed; while for the Sturgeon magnet of the same size, a large and expensive battery was necessary. Then the difference in power was great. Henry continues:

> "Another convenient form of this apparatus was contrived by winding a straight bar of iron 9 inches long with 35 feet of wire and supporting it horizontally on a small cup of copper containing a cylinder of zinc;—when this cup, which served the double purpose of a stand and the galvanic element, was filled with dilute acid, the bar became a portable electro-magnet."

These articles were exhibited to the Albany Institute in March, 1829.

Finding how much those little willing plates could do, Henry now called upon them for something more.

> "The idea afterwards occurred to me," he said, "that a sufficient quantity of galvanism was formed by the two small plates to develop, by means of the coil, a much greater magnetic power in a larger piece of iron.—To test this a cylindrical bar of iron, ½ inch in diameter, and about 10 inches long, was bent into the form of a horse shoe, and wound with 30 feet of wire. With a pair of plates containing only 2½ square inches of zinc it lifted 14 pounds avoirdupois."

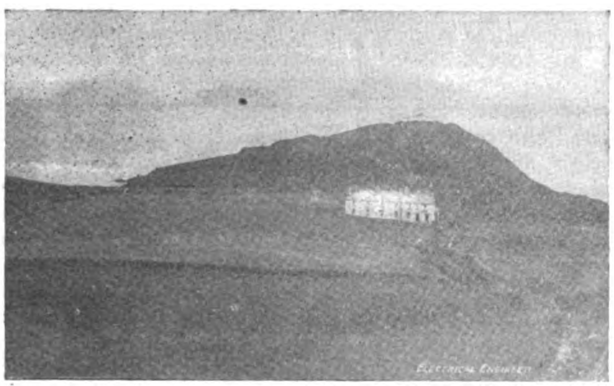
Surely the strength of the magnet was increasing rapidly.

Note: In Chapter II [THE ELECTRICAL ENGINEER, January 10, 1894] the illustration of "De la Rive's ring" would have been better had it shown merely a turn of wire proceeding from the plates. The figure given shows a flat ring which might be taken to include a coil of many turns; whereas the "ring" was originally only a piece of wire bent in ring form.

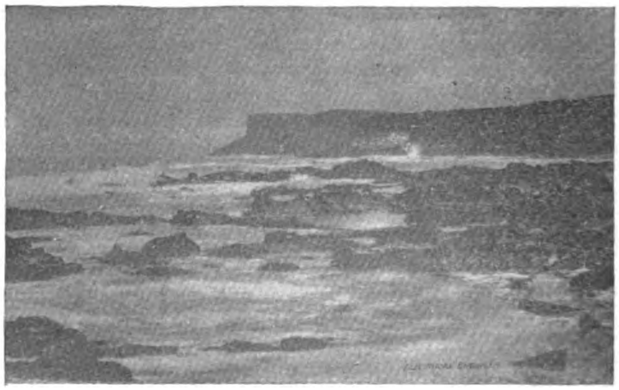
ELECTRICAL UTILIZATION OF THE IRISH SEA TIDES.

BY W'R. LODIAN.

THIS is certainly the age of great engineering projects in bridge building, canal digging and tunnel cutting, while the later years of the century have seen the promotion of several notable schemes for power transmission, among which perhaps that at Niagara is the most conspicuous. The Niagara engineering enterprise rests upon the broadest grounds of feasibility, and the stability and skill with which its plans are being carried out give every promise of a brilliant and enduring success. Of some of the other projects, it is impossible to say as kind a word, strong as may be one's sympathies with daring and enterprise. In this category of the visionary, yet very interesting in its scope and suggestiveness and worthy of record, is the plan seriously proposed for the electrical utilization of the tidal currents of the Irish Sea.



TOR POINT, COUNTY ANTRIM, IRELAND.



FAIRHEAD, COUNTY ANTRIM, IRELAND.

Early in February last the writer concluded a series of hydrographic surveys on the Antrim coast of Ireland, and it was late in August ere a photographic acquaintance, Mr. R. Welch, of Belfast, fulfilled his promise to send views of the ground covered. This delayed the publication of this report, which it was desired to illustrate.

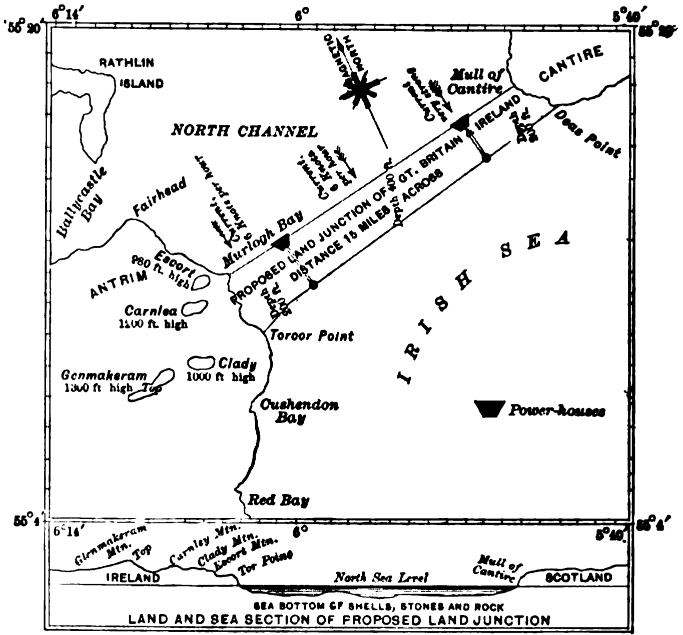


CHART SHOWING THE PROPOSED CAUSEWAY.

The writer was specially detailed to report upon a project to connect Britain and Ireland by a land junction. It was pronounced practicable, but the question was asked: What is the use? That part of Ireland is as wild as Africa. Mr King, the engineer, should build his land junction some hundreds of miles further south—between Calais and Dover. A land junction between France and England would be all above ground and of more stability than bridge or tunnel. As there could be three or four passages for vessels, marine traffic would not suffer interference. But unfortunately, Parliament would never sanction the construction of such an isthmus.

The primary feature of the projected land-junction will be its power-houses, and their use in the generation of electricity from the strong currents always prevailing in that part of the Irish channel. The water-power there running to waste is such that, if utilized, power and lighting could be supplied to the districts for hundreds of miles around. Two power-houses would be ample; one for supplying the Scotch side, the other for the Irish side, and a railroad would run along the isthmus from Cantire to Antrim.

While in the present state of the project, it would be "too much to reveal too much,"—a few extracts may be made from the official specifications, which will show what the constructing engineer proposes to do, and how.

In a direct line north-west of London about 365 miles, and north of Dublin about 126 miles, is the narrow passage between Ireland and Scotland, at the mull of Cantire. The gulf stream, supplying the continuous current flows from the North sea into the Irish sea in volumes of water estimated at many cubic miles daily. The waterway between the head land of Cantire in Scotland and Torhead in Ireland is 15 miles wide, 474 feet deep at mid-current, but much shallower toward either shore. This is the position selected as offering the best engineering facilities for the creation of an isthmus as shown on the chart. The high bluffs of Cantire and the still higher land comprising mounts Clady, Escart and Carnlea near the Irish coast, from 900 to 1200 feet high, offer facilities for gravitating the materials requisite to form the isthmus between the opposite shores. The superficial extent of land required to form the isthmus would be a little more than a square mile, of the average width and depth of 100 yards.

There are no engineering difficulties in the way to prevent the immediate commencement of the undertaking, if favored by national approval and commercial enterprise. The importance and value of the results in the present aspect of affairs in Ireland, cannot be over-estimated. A land junction of Great Britain and Ireland would create a more perfect homogeneity of the united peoples. It would change the Irish Sea into a landlocked bay—lessened in depth by the cessation of the Atlantic current from the north, thereby serving to aid the natural drainage of the adjacent coasts, and make the marsh land of the east coast of Ireland capable of the highest forms of cultivation.

The cost of creating the isthmus would be about two million pounds sterling, and the time it would occupy would be about three years. To maintain a passage of ships to and from the North Sea to the Irish Sea, the Canal of Crinan might be enlarged and another cut through the isthmus of Tarbert.

THE TELEPHONE PATENT SITUATION.—II.

In The Electrical Engineer of Jan. 17th the claim of the patent of Thomas A. Edison No. 474,232 was printed in full; this is the only one of the Edison microphone patents advertised by the American Bell Telephone Co. as covering carbon transmitters. Reference was also made in these columns to the other two Edison transmitter patents. As these patents have been referred to by some journals as being unimportant it may be well for readers to judge for themselves of their importance. Here are the claims:

Claims of patent No. 474,230 of May 3, 1892. Application filed April 27, 1877. Patented in England July 30, 1877.

1. In a speaking-telegraph transmitter, the combination of a metallic diaphragm and disk of plumbago or equivalent material, the contiguous faces of said disk and diaphragm being in contact, substantially as described.

2. As a means for effecting a varying surface contact in the circuit of a speaking-telegraph transmitter, the combination of two electrodes, one of plumbago or similar material, and both having broad surfaces in vibratory contact with each other, substantially as described.

Claim of patent No. 474,232 of Thomas A. Edison, May 3, 1892. Original application filed July 20, 1877, divided and this application filed Feb. 18, 1886. Patented in England July 30, 1877.

A spring forming or carrying one electrode of the circuit of a telephone and constantly pressing against the other electrode and diaphragm to maintain the required initial pressure between the electrodes and yield to the movement of the diaphragm, substantially as described.

Those who are of the opinion that the Blake transmitter, (now that the Blake patents have expired) is subordinate only to the Berliner patent and to Edison No. 474,231, will do well to look carefully at the claim of patent 474,232, even though this patent is not advertised by the American Bell Telephone Co. and would seem to cover only a minor structural device. One of the Government's best points in the suit now pending against the Bell Co to annul the Berliner patent is that several patents of Emile Berliner involving the microphone principle have already had nearly their full term of seventeen years' protection. Among such patents granted to Berliner are Nos. 224,573, 225,790, 241,912, 234,744 and 233,969, the last named being dated November 2, 1880, and being a division of the original application of June, 1877. In this patent are shown the same drawings as appear in the Berliner transmitter patent whose validity is now in question. In fact the patent covers identically the same apparatus so far as mechanical construction is concerned, only the claims upon the device are for its use as a receiver. The application was filed Sept. 3, 1880 and the claims are as follows:—

1. The herein described method of producing sound vibrations in a plate by causing a varying electric current to pass to the plate, or to an electrode connected therewith, from a second electrode in contact therewith, substantially as described.

2. An apparatus for producing sound by means of a varying electric current, which consists of a plate forming or carrying an electrode placed in contact with another electrode, from one to the other of which the electric current is caused to pass.

3. An electric-telephone receiver to be operated by varying electric currents, and consisting of two contact pieces with an electric circuit, one or both of which pieces consist of or are connected with a vibratory diaphragm, whereby one electric current passing through said circuit exercises a repulsion between said two electrodes corresponding to its strength, and thus produces corresponding motions in the diaphragm.

4. A system of two or more telephone instruments in electrical connection with each other, each consisting of two or more poles of an electrical circuit in contact one with the other, either or both poles of each instrument being connected with a vibratory plate, so that any vibration which is made at one contact is reproduced at the other, substantially as set forth.

The application for a patent upon the same organization was filed June 4, 1877, and, after the division above noted, the transmitter patent did not issue until November 17, 1891, as previously pointed out. However long it may take the Government suit against the Berliner transmitter patent to reach a final decision by the Circuit Court of Appeals, or perhaps the Supreme Court of the United States, the device shown and described will be free to the public for use as a receiver on November 2, 1897. In the event of the Berliner transmitter patent being sustained, the condition of affairs from a purely theoretical and legal point of view will be interesting and complex for, whether the device infringe or not will depend upon whether the user places his mouth or his ear to the instrument. In the former case, according to the letter of the law, by using his mouth he will infringe the Berliner patent of Nov. 17, 1891, while in the latter by using his ear he will be free to use the instrument as a receiver in view of the expiration of the patent upon it as such, and he would therefore not infringe. As the device is of no practical use as a receiver, such a question is unlikely to come up; nevertheless a contemplation of this state of affairs is interesting and instructive. As to the three Edison microphone patents, while a decision in the Bate refrigerator case favorable to the Bell Co. would seem to give them the protection of these patents for seventeen years from May 3, 1892, at least one other question would have to be decided—that is, Was the Commissioner of Patents justified in issuing these patents after they had run their full term of fourteen years and had expired in England?

One of the greatest improvements in transmitters was covered by the two patents of Henry Hunnings, a resident of Rothwell, Leeds, England. The first of these patents is No. 246,512 of Aug. 30, 1881. The American application was filed May 14, 1881. The invention was covered by an English patent dated Sept. 16, 1878. The second patent of

Hunnings is No. 250,250 of Nov. 29, 1881. The American application was filed Sept. 30, 1881, while the invention was covered by the same English patent above referred to bearing date of Sept. 16, 1878. The following are the claims in full of both patents.

No. 246,512.

1. As a tension-regulator or means for varying the resistance in telephone transmitters, finely-divided carbon in a loose and free state, substantially as described.

2. The combination, in a telephone transmitter, with a body of finely-divided carbon in a loose and free state, of a vibratory plate or diaphragm for varying the electrical resistance of said body in accordance with its its own vibrations, substantially as described.

3. A telephone-transmitter comprising a thin metallic or metal-covered diaphragm, a back plate, a layer of finely-divided carbon or similar conducting material in a loose and free state inclosed between said diaphragm and back plate, and in a suitable case, substantially as described.

No. 250,250.

1. As a tension-regulator or means for varying the resistance in a telephonic transmitter, finely-divided conducting material in a loose and free state, substantially as described.

2. The combination, with a body of finely-divided conducting material in a loose and free state, of a vibratory plate or diaphragm for varying the resistance of said body, substantially as described.

In the case of these two patents there is no doubt whatever as to the operation of Section 4887 of the Revised Statutes, as the invention was patented in England before the United States application was filed; these patents therefore expired in the United States on Sept. 16, 1892. The long distance transmitter of to-day is frequently referred to as the "Hunnings transmitter." This is a mistake. Two long steps have been taken between the Hunnings transmitter as shown in the above named patents and the beautiful long distance transmitter of the American Bell Telephone Co.—first, in the preparation and perfection of a granulated carbon that is hard, sensitive and that will not pack; second, a transmitter organization which is more efficient than that shown by Hunnings in his patents. As to the granulated carbon used to-day—a carbon which is curiously protected both by a patent and by a secret process—perfection has been reached only after years of research and experiment. The patent covering such carbon is that of Thomas A. Edison, No. 406,567 of July 9, 1889. The application was filed Feb. 19, 1886. The following are the claims.

No. 406,567.

1. An electrode for telephones composed of a body of granules of carbonized hard coal, substantially as set forth.

2. In a telephone, the combination, with a diaphragm, of an electrode composed of a body of granules of carbonized hard coal included in the circuit and acted upon by the diaphragm to vary the resistance of the circuit, substantially as set forth.

3. In a telephone, the combination, with a diaphragm, of an electrode composed of a body of granules of carbonized hard coal, and metal surfaces between which such body of carbon-granules is held, one of such metal surfaces being controlled by the diaphragm, substantially as set forth.

There are many kinds of hard coal and differentme thods of preparing carbon from it. The Bell company have made this the matter of study for years; the particular kind of hard coal which is used, and the process by which the powder is prepared, are kept secret even from most of their own employes. There are, however, other good carbon powders available, such, for instance, as artificial or treated powders. A reference to the patent of J. H. Irwin, No. 238,784 of March 15, 1881, discloses the following claims: "A telephone or microphone resistance contact treated or saturated with a non-conducting substance or liquid." A more recent patent covers the use of paraffine in such treatment. If the American Bell Telephone Co. are in possession of the Irwin patent it can be well understood why they should not lie awake nights over the paraffine patent above referred to. The second and perhaps most important step towards the perfected long distance transmitter was taken by the late Anthony C. White, whose invention is covered by patent No. 485,311 of March 24, 1892. While long distance transmitters have stamped upon them dates of other patents, the American Bell Telephone Co. either through accident or through design, seem to have omitted to place the date of this most important patent upon their instruments involving the invention—at least upon some of them. This instrument is known among telephone people as the "Solid-back" transmitter and was illustrated and described by THE ELECTRICAL ENGINEER in its issue of November 16, 1892, page 477. Preece and Stubbs in their new work on the telephone have taken their description amd illustrations from that article, giving credit to THE ELECTRICAL ENGINEER. The claims of the patent upon the "solid-back" transmitter are as follows:

1. The combination, with the sound-receiving diaphragm D and a supporting-frame therefor, of the independently-supported heavy chambered block W and electrode B, secured thereto, the flexible disk *m*, and piston-electrode E, carried thereby, and the finely-divided conducting material within the chamber in said block and extending about the periphery of said piston-electrode E, substantially as described.

2. In a granular button for a transmitting-telephone, the combination, with the heavy chambered block W, electrodes B and E, and finely divided conducting material P, of the mica spring-disk *m*, carrying the electrode E and confining said granulated material within the chamber in said block W, substantially as described.

The "solid-back" transmitter seems to depend largely for its sensitiveness upon the countersunk recesses for the reception of the granulated carbon; in other words, the efficiency of the transmitter is due to friction as well as to variable pressure, and while there is an actual compression of granules of carbon by the piston electrode, yet there is also a difference of resistance due to the varying number of particles lying directly in the circuit.

One of the most interesting and beautiful inventions touching telephone transmitters is covered by Mr. T. D. Lockwood, in his patent No. 435,438 of Sept. 2, 1890. The first claim of this patent is:

1. The hereinbefore-described improvement in the art of transmitting articulate speech, which consists in transforming an electric current which varies in strength only into a current or series of currents varying also in direction, the potential being unchanged, and in then transforming the said alternating currents into a second series of alternatiug currents, and in simultaneously raising the potential under which the last series is developed.

Those interested in the possibilities of the induction coil will do well to send for this patent and examine it carefully. The specifications and claims are also a masterpiece as to both terseness and inclusiveness. There are more than a hundred minor transmitter patents which are hardly of sufficient importance to be touched upon here, but which should be familiar to the would-be inventor or investor; these patents cover for the most part special mounting either of electrodes or of diaphrams.

Summing up the patent situation as regards the carbon transmitter, there is no broad patent covering the use of carbon in transmitters; there is a patent covering the use of the special powder employed in the long distance transmitter; the Blake transmitter is still covered by the patents of Berliner, Edison and others; the Hunnings patents, covering the use of granulated carbon, expired in this country on Sept. 16, 1892, and the use of such carbon is free, provided a transmitter structure is employed whose action does not depend upon variable pressure between electrodes in constant contact, and also provided that no induction coil is used; the broad patent upon the use of the induction coil in connection with battery transmitters will expire Jan. 15, 1895, after which should a non-infringing carbon transmitter not have appeared meanwhile, inventors may find it profitable to turn their attention to liquid transmitter patents covering devices in which the variation of resistance is effected by a variation in the amount of immersion.

THE electrical engineer of one of the leading electric railway roads of the South writes us in renewing his subscription: "**THE ELECTRICAL ENGINEER** is indispensable to the practical man."

SELF INDUCTION AND BI-METALLIC TELEPHONE WIRES.

BY

A. N. Mansfield.

RECENT articles in THE ELECTRICAL ENGINEER show the important role played by inductance in the transmission of telegraphic and telephonic signals, and attention was called in an article in the ENGINEER of January 10, to the remarkable properties possessed by bi-metallic wires. In connection with this article it will be interesting to inquire into the difference in inductance possessed by bi-metallic and ordinary copper circuits.

The effect of self induction is to annul, to a certain extent, the harmful properties of capacity; but it is very important to take cognizance of the fact that this capacity is equally distributed along the line. If we have a circuit with a localized capacity we can overcome its effects by the insertion of a localized inductance. It may not be necessary to completely overcome this effect but simply to properly proportion the capacity and inductance so as to make the circuit resonant. This resonance would be for a stated rate of alternation and would answer for rapid telegraphic work, but not for the telephone. It is seen therefore, that in order to act on a distributed capacity such as a telephone line we must have a distributed inductance. Let us examine a few of the ways in which this may be attained.

First: Increasing the distance between our wires. While this would increase the inductance and diminish the capacity a limit is soon reached by the dimensions of the pole line.

Second: Diminishing the diameter of the wires. While this would increase the inductance it would also increase the resistance of the wire, in as large a ratio, which is not practicable.

Third: By the use of iron wires. Here we would have a marked increase in inductance and also in resistance. The resistance increase will be very marked on account of the skin penetration and would be large for high rates of alternation.

Fourth: By the use of an iron wire with a coating of copper. The copper coating gives the conductance, but the iron is very poorly situated for increasing the inductance. It is important to note that in all cases we must bear in mind the effect of the skin penetration.

Lastly, consider the case of a copper conductor surrounded by a dielectric impregnated by iron dust. Here we have the conducting properties of the copper and the increase in inductance due to the surrounding ferruginous dielectric. We might take as a limiting case of this a bi-metallic wire, copper core and iron sheath. In this limiting case we have increased the resistance owing to the proximity of the iron, but to what extent must be determined by experiment.

The method of increasing the inductance by the insertion of inductance coils does not appear to be wholly feasible, as we are treating distributed capacity by a number of localized inductances. In the limit we would have a line made up of inductance coils, which is impracticable.

It would appear then, that the proper way to insert inductance would be by the use of a wire made up of a copper core and an iron sheath. A large amount of experimental work would be necessary in order to determine the proper dimensions of the copper and iron. It has been pointed out that in the case of distributed capacity we do not get the maximum current effect by neutralizing the capacity by an inductance, but by so proportioning them that we have a resonant circuit. Hence the proper field of work appears to be, to increase the inductance until we have made the circuit resonant.

Further reference to methods of increasing the inductance of pole lines will be found in the articles by Heaviside on "Electromagnetic Theory" in the London *Electrician*, especially under date of November 3, 1893.

THE LIMITATIONS TO LONG DISTANCE TELEPHONY.—IV.—(*Concluded.*)

BY

F. W. Dunbar

COMPARING the resulting currents at the distant end for the several cases we have :

First.—When C and L are each zero and the equation reduces to $I = -\frac{2E}{lR}$ which is Ohm's law with its proper sign

$$I = -\frac{2E}{2{,}000 \times 2.2} = -2E \times .000228 \text{ ampere.}$$

Second.—$C = 0$ and $L = .0016$ (the probable value of L on the Chicago line).

$$I = -\frac{2E}{l\sqrt{R^2 + L^2\omega^2}} = -\frac{2E}{2{,}000\sqrt{4.84 + 2.56}} =$$

$-2E \times .000184$ ampere.

Third.—$L = 0$ and $C = \frac{.017}{10^6}$ (actual value of C on Chicago line).

$$I = -\frac{2E\sqrt{C\omega}}{\sqrt{R}\, e^{\left(\sqrt{\frac{CR\omega}{2}}\ \frac{l}{2}\right)}} = -2E \times \frac{4.12}{1.49\, e^{4.32}} =$$

$-2E \times .000037$ ampere.

Fourth.—$L = .0016$ and $C = .017$ (condition in practice on Chicago line).

$$I = -\frac{2E\sqrt{C\omega}}{\sqrt[4]{R^2 + L^2\omega^2}\ e^{\left(\frac{l}{2}\sqrt{\frac{C\omega}{2}}\sqrt{(R^2+L^2\omega^2)^{1/2} - L\omega}\right)}} =$$

$$-\frac{2E \times 4.12}{10^3 \times 1.65 \times e^{3.06}} = -2E \times .000122 \text{ ampere.}$$

Fifth.—$C = .017$ and L that value which will make I a maximum, *i. e.*, $L = \frac{C l^2 R^2}{16} = .0204$. The exponent of e will in this case be small and it becomes necessary to determine the wave length and from it the ratio of l to x_λ. This ratio will determine whether the exponential factor should take the maximum, minimum or mean value

$$\frac{e^{\frac{pl}{2}}}{e^{pl} - 1},\quad \frac{e^{\frac{pl}{2}}}{e^{pl} + 1} \quad \text{or} \quad \frac{1}{e^{\frac{pl}{2}}}, \text{ respectively.}$$

$$\text{From (7) } x_\lambda = \frac{2\pi}{\sqrt{\frac{C\omega}{2}}\ \sqrt{(R^2 + L^2\omega^2)^{1/2} + L\omega}} =$$

$$\frac{6.28 \times 10^3}{18.62} = 335 \text{ miles.}$$

Hence $\frac{l}{x_\lambda} = 6$, approximately. Therefore the current equation assumes its maximum value $\frac{e^{\frac{pl}{2}}}{e^{pl} - 1}$.

Substituting we obtain :

$$I = -\frac{2E \times 4.12\, e^{1.00}}{10^3 \times 4.53\, e^{2.00} - 1} = -2E \times .000384 \text{ ampere.}$$

Had $\frac{l}{x_\lambda}$ been 6.5, and therefore the exponential of minimum value, the factor $e^{2.00} - 1$ would have changed to

$e^{2.00}+1$ and $I = -2\,E \times .0003$ ampere. These calculations show that were it possible to maintain the capacity of the Chicago line constant and to increase its inductance from zero to .0204 henry per mile, the value of the current at the distant end would gradually increase from $.037 \times 2\,E$ milliamperes to a maximum of $.38 \times 2\,E$ milliamperes; and that the value of the inductance which occurs in reality, although less than one-tenth that value which renders I a maximum, yet brings the current to one-third its maximum value. At the same time it is but little over one-half the value that would be obtained were the line devoid of capacity and inductance, and but two-thirds the value that would result were the line free from capacity alone.

The important result, however, is, that by the addition of suitable capacity and inductance a value of the receiving current may be obtained greater than that which would be obtained were the line free from both capacity and inductance.

Formula (12) may be written

$$\frac{l}{2}\sqrt{\frac{C\,\omega}{2}}\,\sqrt{R.} = 1 \qquad (13).$$

This value $\frac{l}{2}\sqrt{\frac{C\,\omega}{2}}\,\sqrt{R.}$ is the exponent of e in (4) and indicates than when the exponent assumes the form e^1 the value of the current at the distant end is a maximum.

From the results just deduced it might appear that the value of the received telephonic current on the Chicago line would be but little affected by the presence of the line capacity. But a further consideration will show what has limited the transmission of speech and caused the insertion of 400 tons of copper wire to conduct a conversation a distance of less than 1,000 miles.

Equation (3) expresses the current at the transmitting end. Substituting we obtain

$$I = -\frac{E\,\sqrt{C\omega}}{\sqrt[4]{R^2+L^2\omega^2}}\;\frac{e^{pl}+1}{e^{pl}-1} = -\frac{E \times 4.12}{10^3 \times 1.65}$$

approx. $= -2\,E \times .00125$ ampere, a value over 10 times greater than the received current and seven times greater than though the line were devoid of capacity and inductance. If the transmitting device were capable of maintaining a constant potential it would have to give out seven times the energy to secure one-half the current at the distant end on account of the capacity of the circuit. But the induction coil used in the transmitting circuit of the telephone is far from being a regulating device. Aside from its relatively high impedance, which of itself enormously reduces the potential at its terminals, the coil is capable of giving out but a definite amount of energy. A demand for more current can only be met by a fall in E. M. F.

Thus on open circuit the coil during conversation frequently exceeds 100 volts; when closed through a voltmeter of a few thousand ohms resistance it gives a potential of 25 or 30 volts; and when connected to a line such as that under discussion it can only furnish two or three volts to the circuit.

Hence we may conclude that the only cause which has limited the extension of long distance telephony, or which seems at all probable to limit its extension—that of the decrement of current due to the capacity of the line—is itself due *to the use of a transmitting device devoid of regulation.* It is not within the scope of this paper, however, to discuss the increased induction disturbances which would be a natural result of the adoption of a transmitter capable of maintaining a constant potential to line.

The importance of the value of the factor R must not be neglected. Equation (11) shows us that the value of L which secures a maximum current varies with the square of the resistance. If then the resistance were decreased from 2.2 to 1 ohm per mile this value of L would reduce to .0041—a value but 2½ times as great as the actual value, and close enough to it to produce nearly the maximum value of the current. A calculation using 1 ohm in place of 2.2 yields

$$I = -\frac{2\,E \times 4.12 \times .334}{10^3 \times 1.37} = -2\,E \times .00100 \text{ ampere.}$$

Thus a decrease of 55 per cent. in the resistance yields eight times the current at the distant end and places the constants in such a relation that no material increase could be secured by a farther increase in the inductance.

A similar course of reasoning shows that the adoption of the 435 lb. wire (per mile), on the Chicago line, in place of the hitherto standard 173 lb. wire, allowed an increase of eleven times the current at the receiving end. Thus, substituting $R = 5$, in place of 2.2, and $C = .014$, in place of .017, we have, $I = -\frac{2\,E \times 3.74}{10^3 \times 148} = -2\,E \times .000011$ ampere.

All of this huge gain was not, however, realized, for reasons already pointed out; the transmitter could not maintain the potential. The substitution of the 435 lb. wire called for an increase of 50 per cent. in the current at the transmitting end and the potential had to decrease to meet the demand and with it decreased the current at the distant end, and in the same proportion.

In conclusion we may say that under the present system the limitation to the transmission of speech by overhead lines is the price people are willing to pay for the privilege. For, by employing about eight times the amount of copper it is possible to double the distance that has already been successfully talked over. But if a constant source of E. M. F. were employed at the transmitting end there would be no apparent limit to the extension of telephony by overhead construction.

It has already been shown, in article I, that the distortion of the *form* of the wave, due to the unequal displacement of phase in the component parts of the complete tone, does not, as assumed by many writers, cause a distortion of the sound as the ear appreciates it and does not impose any limit whatsoever upon long distance telephony.

It has also been shown in articles II and III that the distortion of the wave due to the unequal decrements of the component parts of the complete tone has never in practice cut any figure in long distance transmission and that when the lines are so constructed as to bring them into "resonance" and thus secure the maximum current at the distant end, even the slight distortion which now theoretically exists, will completely disappear even upon the longest lines.

The problem of a cable is different only in respect to the relative values of the constants C and L. As the two sides of the circuit approach one another the capacity increases and the inductance decreases. This increases the discrepancy between the actual value of L and that value which will produce a maximum current at the distant end. But if the inductance be increased either by separating the return wire, or by the addition of artificial retardation, or by a combination of the two methods, one circuit at least could be rendered capable of almost indefinite extension.

CONDUCTING POWER OF DIELECTRIC LIQUIDS.

If it be assumed that electrical conductivity in dielectric liquids is of the nature of electrolysis, we must look for galvanic polarization in two electrodes inserted in it and connected with a galvanic battery. A capillary electrometer, in which the electrolyte is the liquid itself to be investigated, may be made so sensitive that the existence of polarization, and also of electrolytic conductivity, may be demonstrated. The thermometer should consist of a horizontal tube about 1 mm. bore, connected on each side with a mercury cup; the mass of mercury in the tube is separated by a drop of the substance to be investigated. If the two mercury cups be connected with the poles of a battery, the drops will move one way or the other, according to the direction of the current, if the liquid conducts electrolytically, and thus when polarization takes place at the opposite surfaces of the mercury.

THE COPPER-ZINC ACCUMULATOR.—I.

BY

D Paul Schoop

At the present time the question of traction by means of accumulators has again come to the front among the topics of discussion by electricians. But more recently it has not been the much-hoped-for and at the same time so much abused lead accumulator, which takes the lead in the discussion, but it is that less known form of secondary battery, frequently called the alkaline accumulator or the copper-zinc secondary battery.

To those not especially engaged in the trade or manufacture of this type of battery, most likely very little will be known about it since the literature on it is meagre and perhaps not more than two dozen patents have been taken out on this type; and even such patent descriptions do not afford much of an insight into this type of battery, so entirely different is it from the better known lead cell on nearly every point of importance. The writer, having had opportunities to study the subject more closely, both from a theoretical and practical point of view, will try in these articles to give an idea of the present state of the copper-zinc accumulator.

This type of secondary battery is of quite recent invention, but its history is, perhaps, as old as that of the lead cell. Without tracing it to its origin, it may be stated, that the French chemist Lalande was probably the first who brought the galvanic combination, viz., copper (in oxydized form): zinc and caustic potash (dissolved in water), into practical prominence. Many years before Lalande's name became known in this country by its connection with that of Mr. Edison in the primary battery known as the "Edison-Lalande" cell, the French chemist had developed the above mentioned combination. Although Lalande calls his combination a primary battery, it is well to remember right here, that it is *reversible* in its action, that is to say, by passing an electric-current in the opposite direction to that delivered by the discharging of the cell, it will again recover to the original state of the cell before the discharge. It is now about ten years ago that Mr. Desmazures, of Paris, with the financial help of Messrs. Bailhâche and Commelin, made his first efforts on a practical scale, to put the Lalande cell into the shape of a secondary battery cell. It is about seven years ago that the French submarine boat "Gymnote" made its trial trips with the Desmazures battery and proved a complete failure.

But since that time electricians have worked steadily on improving the copper-zinc accumulator. At the beginning of last year, the firm, Messrs. Pulsford & Triquet, of Paris, looked into the Desmazures cell, but nothing has as yet been heard of putting the accumulator into practical use. If the writer is correct, three years ago Messrs. Phillips and Entz took up the question anew, and so far have gone farther than any one in putting the copper-zinc cell into practical use. Owing to a peculiar and, no doubt, ingenious construction of the copper-anode (Mr. Phillips' mat of copper-cable), certain defects of the Desmazures cell have been eliminated, whilst the result of the trial with six cars on Second avenue, New York, may perhaps prove that the general working conditions of the Wadell-Entz accumulator are at least so far advanced as to render this apparatus capable of more extensive use. Dr. Boettcher in Leipsic, Germany, has devoted several years of study to the solution of the copper cell question; so also has Professor Aron, who took up the subject ten years ago, and added much to our knowledge on it. Americans also well remember the late Mr. Slattery, who worked in this line, and no doubt a good many others have gone in for the same object.

The history of accumulator traction is not a happy one; nowhere has this mode of traction achieved a complete success as yet, although all the better systems of accumulators have been tried and sometimes under good conditions. Like a will-o'-the-wisp, the coming accumulator for traction work has thus far kept at a safe distance. Will the copper-zinc cell follow the same example or will it be of a a less deceptive character? Is it likely to be "practical?" Will it require more or less attention during its life than a lead cell? Will it be more durable, more reliable, as efficient as the lead cell? These, and many similar questions must arise before an exact estimate on any practical scale will be possible. And after knowing a little about those details, reports from several quarters, as many as possible, should be forthcoming, telling the tale of praise or dispraise, as it will be, according to the merits of each accumulator.

In what follows the writer proposes, first, to give the chemical foundation of the copper cell; afterwards a short description of the Desmaszures and of the Phillips-Entz (Waddell-Entz) cell will follow and then the peculiarities of this type of accumulator will be treated of.

Lalande's cell. If a copper-sheet, whose surface is covered with the black oxide of copper, is placed in a vessel, filled with a solution of 1 part of caustic potash in two parts of water, and a zinc plate is placed opposite the copper sheet, a primitive form of Lalande cell is established. By closing the circuit, that is, connecting the copper with the zinc plate, a current is set up. After some time, all of the black oxide of copper will have disappeared and a brick-red color of the copper sheet will first be noticed, indicating that the oxide of copper has been changed into a lower oxidized form, the suboxide of copper, which has a red color. But after a short while, the red appearance vanishes and the more yellowish, bright, metallic tint of pure copper manifests itself. On the other side it will be noticed, that the caustic potash solution (the electrolyte) dissolves part of the zinc plate; heavier streams of liquid sink down along the zinc plate, as may be seen by looking through the glass cell. The caustic potash solution has taken up some of the zinc, in the form of zincate of potash, as this zinc compound is called. As long as there is a trace of the black oxide of copper, the difference of potential between the terminals of the cell is 1.03 volt; but when the red suboxide of copper only is present, 0 85 volt difference of potential will be found between the two electrodes and it is safe to say, that not the slightest trace of oxygen will be found at the copper side, when the potential has fallen to zero.

The electro-chemical process is perhaps as follows: The zinc decomposes the caustic potash (K O H) by absorbing its oxygen and thus forming oxide of zinc. Of course there remains potassium as a free element. Now neither of these two newly formed bodies can exist unaltered under the present conditions. The oxide of zinc dissolves in the excess of the caustic potash solution, forming the already mentioned streams of heavier liquid, sinking down along the zinc plate. The potassium decomposes the water of the potash solution and combines with its oxygen, forming again caustic potash (which dissolves in the surrounding solution), while hydrogen is set free. But no gaseous hydrogen can be seen, since it is at once absorbed by the oxide (or suboxide) of copper, thus reducing the oxidized copper to its metallic state while the result of this last combination between the hydrogen and the oxygen of the copper oxide (or suboxide) is water, the latter mixing again with the surrounding liquid.

ELECTRIC TRANSPORTATION DEPARTMENT.

ELECTRIC ROADS IN COUNTRY DISTRICTS.

In a recent communication from Columbus, Ohio, the New York *Evening Post*, presents the following interesting data on the subject of electricity as applied to country roads the State of Ohio:—

The discussion of road improvement has received a unique and original contribution in the report of an Ohio commission appointed last spring by Gov. McKinley, under direction of the Legislature, to investigate the subject in all its relations. The Governor appointed Martin A. Dodge of Cleveland, the author of the resolution who is an enthusiastic advocate of the application of electricity to country roads, David S. Oliver of Cincinnati, J. H. Dunlap of Hardin County, and D. W. Sprague of Lake County upon the commission. A careful investigation was carried on throughout the summer, and the result is a report of more than usual interest.

It shows that in two-thirds of the counties of Ohio there are nothing but common dirt roads; which are well-nigh impassable a third of the year. The cost of macadam-turnpikes ranges from $1,500 a mile in counties like Miami and Union, where a good quality of gravel is ready obtainable, to $10,000 a mile in Muskingum, where limestone is the only material available. The mileage of common roads in the state is 80,000 in round figures, and only 11,500 miles are improved, 7,000 macadam, and 3,500 gravel. The cost of moving freight over the roads of the state is reported to vary in different counties from 10 to 25 cents a ton. The commission estimates that it would require the enormous sum of $400,000,000 to improve all the roads in Ohio, and that even then the actual cost to the farmer of transporting his products to market would exceed 10 cents a mile and probably approximate 25 cents per ton. In the city of Cleveland, with paved streets, for example, the commission's inquiries lead to the conclusion that the average cost of drayage is not far from 25 cents a mile per ton. The commission holds that comparisons prove "that the steam cars and the electric cars have already contributed more to cheapen transportation without the aid of public money than the wagon-road improvement has done with the aid of public money."

Regarding the proper authorities to be charged with road improvement the report says:

Without going into an exhaustive discussion of the subject, we are convinced that national or state aid is unwise, and that with the governmental machinery existing in Ohio, the county authorities are the proper ones to manage road construction, and that the necessary funds should be raised within the limits of the county where the roads are built. The community of interest in a county is such that it may properly be considered a unit in the matter of road building, and the fairest plan for all concerned is, perhaps, to assess a portion of the cost upon the abutting land, and place the balance upon the general tax duplicate. . .

The people who use a road are those living in the immediate neighborhood. Statistics are not at hand, and perhaps could not be gathered, but it is safe to say that the average haul on our roads is not over five or ten miles at the outside. No one would pretend for a moment that a pike between Cincinnati and Cleveland was necessary or desirable on account of the through traffic between those cities. Further, it is largely a matter of indifference to the citizens of Cincinnati whether there are good roads leading into Cleveland or not. They are only concerned with the condition of the roads about their own city. Therefore, it cannot be asserted with any degree of truth that the building of roads is a concern of the state at large, and that the state as such should raise money by taxation to be expended by her in improving the roads where good roads are lacking.

Regarding the application of electricity to the country road, the commission begins with this interesting paragraph:

There is another consideration that should deter us from entering upon any extensive scheme for improving our roads requiring the expenditure of vast sums of money. It is a significant fact, to which attention has been frequently called, that the history of the development of the means of transportation shows no instance in which, after a better means has been devised, mankind has gone back to a former method. Every improvement in the means of transportation reduces the comparative value of the former means of transportation and frequently destroys is altogether. The bridle-path and the pack animal disappear as soon as wheeled vehicles are placed upon the common roads in competition. The ox-team is abandoned for horses, and the post-rider for the stage-coach. These, in turn, all give way and disappear wherever it is possible to introduce a steam-car or an electric car. It is undeniable that the development of the railway arrested the building of wagon-roads on a large scale, such as the "National Road" running through Ohio. The horse-car in cities superseded other methods for carrying passengers, and the electric and cable-cars have about rendered the horse-car obsolete. With the advent of the electric car has come a development along a line totally unexpected, and that is its extension into the suburban and rural districts. It is too early to predict the extent to which the building of electric railways in the country districts will be carried. The franchises that are being granted for construction of electric lines connecting different towns would seem to indicate a possible expansion in this direction hitherto unthought of. There are no reason why these railways should not be carriers of freight as well as passengers, and it is not at all visionary to surmise that as the steam railway superseded horse-power for long hauls, so the electric railway may supplant it for short hauls.

A diagram is presented showing the relative distances over which $1.25 will carry a ton of freight on wagon, electric road, steam railway, and lake steamship. They are respectively 5, 25, 250, and 1,000 miles. The commission concludes "that steam-cars and electric cars are both better means than horse-power, so far as they can be applied," and it continues:

This may certainly be assumed: That we are only at the threshold of the door that leads to a more extended use of inanimate power to take the place of animal power as a means of transportation; that more electric roads will be built; that they will be almost innumerable, in fact unlimited, is evidenced by every indication, so that the problem of building the wagon-road is made easier and easier by reason of the shortened distances for which horses may be profitably used for purposes of transportation. Five miles will probably measure the distance beyond which the horse cannot be used either for pleasure or for profit. It should also be observed that the ordinary earth road when in good condition, as it is during most of the year, is more suitable for light purposes and pleasure driving than macadamized roads or roads made hard with any kind of metal. By introducing the iron rails and inanimate power for rapid transit, and to take the heavier loads, the problem is solved.

The commission accordingly recommends "masterly inactivity" in the matter by the Legislature and discourages schemes calling for large expenditures and involving a heavy increase in local indebtedness,

A minority report signed by Martin A. Dodge and D. W. Sprague, two of the commission, goes much further than the main report in advocacy of electric roads through the country districts. It shows that the power necessary to move a ton of freight over steel rails is one-eighth that required on a macadam road, one-eighteenth that on a graveled road, and one-twenty-fifth that on a common dirt road in fair condition, and declares that "the profitable use of steel rails and the application of inanimate power can only be limited by the convenience or inconvenience of terminal facilities." The conclusions of this minority report are radical and are summed up in the following paragraph:

It seems probable that the application of electricity to the cars upon our streets and roads is destined to do for the short haul what the steam-cars have alrady done for the long haul. So far as electricity has been applied already, it has shown that the cost of transportation by that means is far less than upon the steam-cars, which is indicated by the rate of charge for transportation—the common rate upon steam-cars being three cents per mile for passengers, while in many cases upon the electric cars it is but one cent or even less per mile. What has been done by way of cheapening transportation of passengers may be done to a great extent in cheapening the transportation of certain kinds of freight, especially the food products that are raised upon the farms and conveyed to the markets for immediate consumption. This may be done either with or without the aid of public money. Neither the steam-cars nor the street-cars, up to the present time, have received the aid of public money; but one element in the cheapening of transportation, which has assisted the electric street-cars, is the use of the public streets and roads, which, though not money, is a contribution as valuable as money itself. The cheap rates which prevail upon the street-cars could never be attained if the companies that operate these cars were obliged to appropriate and buy the lands upon which they build their roads; so that public aid, though not public money, has been given—and properly given—to cheapen transportation by that means.

In the article on "Electric Chain Traction for Canals," by Mr. Jules Neher, in our issue of Jan. 17, a typographical error in the third paragraph made it read that "rolling traffic is *cheaper* than floating." It should have read, "*quicker*."

A PLAN OF TROLLEY LINE REGULATION FOR BROOKLYN.

Mayor Schieren has been considering the trolley question since he has entered upon his duties as Chief Magistrate of Brooklyn. He enjoys unusual advantages for observing the work of the trolley cars, as nearly all the lines in the western district run past the City Hall.

During the morning and evening "rush hours" and in the afternoon when the shopping traffic is heaviest, there are almost continual blockades of trolley cars on Fulton street, opposite the Mayor's office. This has impressed the Mayor with a sense of the gravity of the situation. He has spent a good deal of time thinking about it.

"I believe it would be a good idea to have inspectors patrol the streets on which trolley cars are run, whose duty it should be to arrest motormen who indulge in reckless running," the Mayor said recently. "I have laid the scheme before the Board of Subway Commissioners, and they are now considering it.

"I am in favor of fixing a maximum rate of speed for the cars which shall not menace the lives of the people. The question is too important to be disposed of hastily, but when I get ready to act, I will present my views to the Aldermen."

President Norton of the Atlantic avenue system says he thinks every person who gets run over by a trolley car ought to be arrested. He says that is the way they do in Berlin, and he thinks the custom a good one. He does not think the motormen who kill human beings should be arrested. People are killed because of their own carelessness.

ELECTRIC "SNUBBING" ON THE ERIE CANAL.

Cruising along a canal and digging the boat's nose occasionally into the bank is known technically among canal men as "snubbing," and it is now intended to electrify that branch of occupation as well as others. Mr. Frank W. Hawley, who had charge of the canal electrical experiments near Rochester in December last, will ask permission of the Superintendent of Public Works to operate his boat on the State waterways next season as a sort of object lesson in the uses of electricity. He proposes to have a new boat of the most approved pattern, equipped with a propeller wheel of the latest design, and in place of the trolley used in the experiments already mentioned, proposes to use storage batteries to operate the Westinghouse motors that drive the shaft to which the wheel is attached. Two series of storage batteries will be used. On one side of the boat will be ranged the chloride accumulators of the Electric Storage Battery Company, and on the other side a series of batteries furnished by the General Electric Launch Company of New York. It is the intention to place upon this electric boat a number of devices for the use of electricity in daily life, and to exhibit these everywhere along the line of the canal.

A NEW KIND OF COUNTER WEIGHT RAILWAY.

The Oil City, Pa., Passenger Railway Company, is about to make a novel experiment in engineering. The company has put in an electric street railway system and is ready to operate its cars. One of the streets has a very heavy grade, both difficult and dangerous, if not altogether impracticable by ordinary means.

It is proposed to assist traction up hill and retard descent by lowering and raising a weight as heavy as a car. A hole 1,000 feet deep has been drilled in the street at the top of the heavy grade, and in this is to be suspended the weight, attached to one end of a steel cable, running over a pulley, while the cars are attached to the other end by an adjustable clutch.

When a descending car has reached the foot of the hill an adjustable clamp holds the weight at the top until an ascending car is fastened to the cable. The weight is then released and descends as the car moves up the grade.

Why two cars are not made to balance one another—the one going up while the other comes down—and the necessity for the hole in the ground avoided, is not stated.

THE LAWRENCE ELECTRIC RAILWAY.

Among those competing for the $50,000 prize offered by the Metropolitan Traction Company, for a railway equal to the trolley system without overhead or other objectionable features, is Mr. William Lawrence of the Lawrence Electric Company with offices at 13 Astor Place. His system employs a conduit of vitrified clay and a sectional trolley wire normally out of contact with the feed wire and entirely dead except during the passage of a car. The conductor sections are of copper wire 32 feet long, each soldered along the flange of a piece of angle iron of the same length, and of sufficient cross section to be quite rigid when supported only at its extreme ends. At the end of each section is a watertight and airtight junction box with a heavy rubber top through which projects a pin adapted to be screwed to the end of an angle iron section and to support it in position.

The lower end of this pin in the box is provided with copper brushes that make contact with a copper plate below when depressed. The weight of the section, however is not great enough in itself to force it downward and it is kept by the air pressure in the box and by the elasticity of the rubber top from completing the circuit except during the passage of the car. The feeder is wholly insulated and all connections are made within the boxes. The car carries a double trolley making contact with one section of conductor before that with the last is broken, in order to minimize the tendency to sparking.

An experimental road is nearly finished and public exhibitions of the system will soon be given.

MISCELLANEOUS.

FOUR THOUSAND NEW YEAR GREETINGS BY TELEPHONE.

A very interesting demonstration of the possibilities of the telephone was made at St. Louis, Mo., on New Year's Day, when with the help of Mr. G. F. Durant, of the Bell Telephone Co., the *Globe-Democrat* called up all the telephone subscribers to wish them a happy New Year. There are three telephones in the business office of the *Globe-Democrat* for the accommodation of advertisers. For this occasion this number was re-inforced by seven instruments, which were placed on the fouth floor of the building. Supt. Durant personally superintended the New Year's calling, which was at the same time a practical test of the efficiency of the telephone service. That it might be the more satisfactory in the latter sense, no special provision was made for the reception and transmission of messages at the central office. The regular list of telephone subscribers was divided into ten portions, in alphabetical order just as printed, and a portion given to Messrs. Berger, Massey, McDonough, Walsh, Fluett, Parker, Lewis, Foster, Farrell and Wolff. The calls were made in accordance with the prescribed rules of the company, which are printed, framed and hung up at the side of every instrument in the city. Half a minute was allowed each station called for to respond before the number was checked off as not answering, and the next number on the list was then taken up. The electric calls were then commenced at 8.30 a. m., and the last of the greetings had been delivered at 11.58.

The best results were achieved by Mr. McDonough, of the telephone corps. He called up 514 stations in three hours and twenty-seven minutes, secured 260 answers, found fourteen busy, five out of order, and 235 not in use for the day. The whole time occupied in the transmission of the messages was thirty-three hours and eight minutes; the average time of each operator was three hours and nineteen minutes, and the average rate was 118 calls per operator per hour, a little the fastest thing in New Year's calling on record.

The following official record was compiled from the individual operative reports by Gen. Supt. Durant:

Station.	Operator.	Started.	Stopped.	Time occupied.		No. of stations called.	Answered.	Reported busy.	Reported out of order.	No. of stations from which no answer was had.
				H	M					
1960	Berger	8:30	11:55	3	25	380	225	20	4	131
1963	Massey	8:40	11:53	3	13	323	166	18	9	130
1965	McDonough	8:30	11:57	3	27	514	260	14	5	235
1966	Walsh	8:35	11:58	3	23	387	232	4	11	140
3985	Fluett	9:20	12:10	2	50	356	154	16	8	179
3986	Parker	9:20	12:15	2	55	373	139	5	1	228
3987	Lewis	8:45	12:25	3	40	363	178	11	8	166
4183	Foster	8:30	11:55	3	25	351	192	15	2	145
4186	Farrell	8:30	12:05	3	35	321	175	10	16	120
4199	Wolff	8:40	11:55	3	15	364	234	31	3	96
	Totals			33	8	3735	1954	144	67	1570

Mr. Durant in discussing the service was very much pleased with the result. There are always a number of telephones reported out of order on New Year's morning, the result of injury to the wires by flying bullets, fired by celebrants of the new year's birth. The general suspension of business in professional and commercial circles accounts for the large number of telephones not answering.

AN EXPERIMENTAL SEARCH LIGHT FOR SANDY HOOK.

The great search light from the roof of the Manufactures and Liberal Arts Building at the World's Fair, forming part of Schuckert & Co.'s exhibit, has been sold to the United States Government, and will be set up at Sandy Hook for experimental purposes.

THE NATIONAL STATISTICAL ASSOCIATION.

We have received a prospectus of The National Statistical Association, organized under the laws of Congress for the District of Columbia. The Association will undertake a service that is much needed by all public service corporations. The work of the company will include the collection, recording and tabulation of such legislative, legal and statistical information as may, from time to time, be found most useful to its clients, and the furnishing of such information to them at stated periods. The companies likely to be specially interested in this service are electrical and gas lighting companies, water companies and street railway companies. The work and business of The National Statistical Association will be under the personal direction and supervision of Mr. Allen R. Foote, Vice-President and Manager. Mr. Foote has made himself well and favorably known in electrical circles through his writings on industrial topics and as sometime Secretary of the National Electric Light Association. His book on The Law of Incorporated Companies Operating Under Municipal Franchises, which was reviewed in The Electrical Engineer of August 23, 1893, has received favorable notice and commendation from many competent sources. The forty-six associate editors of that work, attorneys in the several states, will, for the most part, be retained in the service of the Statistical Association. In addition to the collection, and supply of statistical information, it is proposed to keep watch upon all state and municipal legislation, effected or proposed, enacted franchise corporations and to report all litigation concerning such companies. It is obvious that the service about to be undertaken by the National Statistical Association directly concerns the interests and future welfare of all electric lighting and power companies. There is a distinct community of interest, or should be, among such corporations, and their adequate support of Mr. Foote's enterprise could not fail to benefit them as clients of the Association.

BI-METALLIC CONDUCTORS.

The article in our issue of Jan. 10 on the use of bi-metallic wires in telephony has created widespread discussion not only in telephonic circles, but in others as well. We publish in this issue a communication from Mr. A. N. Mansfield on the same subject. In the lecture delivered by Dr. M. I. Pupin before the New York Electrical Society last week on "Electrical Resonance," reference was also made to the bi-metallic wire. In both the above instances the authors, though expressing themselves guardedly, point out that theoretically at least there ought to be a gain in the use of such a wire. It is also brought out that greater benefit would be obtained by putting the iron on the outside of the copper instead of employing it as a core. Thus far the discussion has been confined to the influence of such a wire on telephone and telegraph lines only, but would it not be worth while to inquire also what influence such a conductor might have on long distance alternate current transmission? It is true that the rate of alternation for power transmission purposes averages far below that prevailing in telephony, but that even with this comparatively low frequency line difficulties are encountered, which become serious when long distances are attempted. The addition of iron to the circuit in all these cases affords a means of adding a self-inductive medium to the circuit, but what is of most importance, a *distributed* self-induction. What effect the employment of such a conductor might have on submarine cable work can hardly be foreshadowed as yet. It would be well, however, not to jump at conclusions as to the all-sufficiency of self-induction in neutralizing the effects of capacity on telegraph and cable lines, even though that self induction be distributed over the whole line. For, while capacity may successfully overcome the effects of self-induction, it does not follow that the reverse holds true in all cases ; and the many futile attempts to improve the speed of telegraph and cable working should invite to caution. Nevertheless we believe that the bi-metallic conductor is well worthy of the most searching study and presents the most promising improvement which has been suggested for some time past.

UNDERGROUND RAPID TRANSIT FOR NEW YORK.

There is distinct merit in the plan which has been proposed by R. T. Wilson & Co., bankers, for an underground electric road in New York city. They offer to build a double-deck road within four years if the city will lend two-thirds of the cost, or, in other words, a sum not to exceed $30,000,000, the city to have in return a first lien for reimbursement. We do not see the particular necessity or desirability of a double-deck system, believing the Greathead direct, individual tunnel method to be better with occasional interlacing of routes; but there is a distinct advantage in going below all existing pipes and subways on the line of Broadway. The road is to pierce the centre of the city, and by so doing will relieve the present serious congestion on the Elevated, besides building up a large new traffic of its own. The practicability of electricity is no longer in question, and all that the citizens of New York now ask for is prompt action.

THE LIMITATIONS TO LONG DISTANCE TELEPHONY.

In this issue we bring to a close the excellent series of articles by Mr. F. W. Dunbar on the above subject. The conclusions arrived at by the author are of a decidedly interesting and important character and show that so far as land lines are concerned, nothing stands in the way of doubling the distance of transmission already successfully accomplished, except the cost, which in that case would entail an eight-fold increase with copper wires. In how far the substitution of a bi-metallic wire would modify this estimate remains to be seen, and it will probably not be long before we will have some practical demonstration on this point. But there is another point dwelt on by Mr. Dunbar which merits attention and which is here brought out for the first time, and that is, the poor regulating qualities of the transmitter induction coil and its effects on the transmission. Much has already been done to adapt the induction coil to better telephonic working but evidently much more still remains. In view of the fact, according to Mr. Dunbar, that the coil on the New York and Chicago line actually furnishes a difference of potential of only two or three volts it seems pertinent to inquire whether better results might not be obtainable with the use of very low resistance storage batteries used directly without the intervention of the induction coil. We are well aware of the steadying action of the induction coil on the telephonic current impulses transmitted, and its influence in maintaining and even enhancing the sharpness of the curves, but it does not seem improbable that an equivalent effect might be obtained by employing other means than the non-regulation induction coil. These questions and many more will without doubt occupy the attention of investigators and inventors in the near future.

NO GOOD BLOCK SIGNALS.

It is rather a curious coincidence that just as the New York Central should get its fine new interlocking and block signal system into operation all the way from Manhattan Island to Niagara Falls, the Delaware, Lackawanna & Western Road should have a frightful accident, in the fog, due entirely and solely to the absence of a block system. The New York Central, with a magnificent disregard of mere expense, has put in no fewer than 1,633 levers with 108 signal bridges, and 60 signal towers. Yet President Sloan of the D., L. & W. has the infinite presumption or marvelous ignorance to rise and say that no block signal system can be depended on and that no system is perfect; ergo, railroads must depend on tired men and little red flags. Either Mr. Sloan impeaches the New York management or he impeaches himself by such statements. He can take his choice. The New York Central has at least the approval of all electricians and railroad men, and their opinions will have some weight with the public. It is the duty of any conscientious management of a road to reduce the chances of accident to a minimum, and to this end it must use every possible appliance of safety, even if it be expensive and even if it be a trifle short of absolute, inerrant infallibility. All Mr. Sloan has to do is to get the best.

POWER UTILIZATION SCHEMES.

The great and eminently feasible project of power transmission at Niagara is finding many rivals and imitations of a more or less visionary nature. As the discussion at the Institute meeting on Wednesday last showed, polyphase current power work is already being developing in a healthy manner, but the pace is hardly fast enough for those who want something big. Of course in days when such vast engineering works as the Manchester Canal, with its thirty-five miles costing $80,000,000, are carried through successfully, there is a ready faith in enterprises merely because they are big, and of that class the scheme of which we make note in this issue for the electrical utilization of the currents in the Irish Sea, by means of a huge causeway with flood gates, is perhaps the most conspicuous. We invite attention to the scheme not because of its feasibility, but because of the curious problems involved in such an attempt and because of the very curious results of all kinds that might follow.

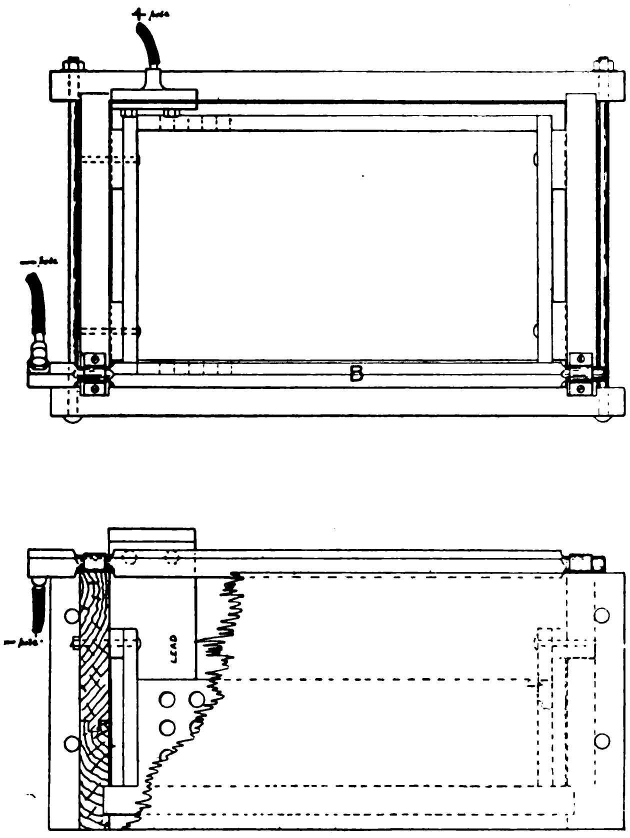
THE ELECTRIC LIQUID METAL HEATING PROCESS.[1]

BY GEORGE D. BURTON.

THE speaker stated that the process consisted in immersing the metal, or that portion to be heated, in a liquid, and passing through both an electric current of such a character as to cause the formation of an incandescent gas envelope at and below the surface of the solution and around the metal. The liquid best suited to the purpose he had found to be a solution of carbonate of soda and borax, composed of ten parts of soda and one of borax, having a specific gravity of 1.25 at 74 degrees Fahrenheit. This does not injure the material heated, but on the contrary, improves it, when the parts are afterward subjected to pressure.

A receptacle, composed of wood, earthenware or other insulating material, shown in Fig. 1, 2 and 3, contains the liquid, and a plate of lead is placed in the bath and serves as an anode, being connected, by means of a conductor, with the positive pole of a direct current generator of either 110, 220, or 500 volts, and from 6 amperes upward, varying according to the size of piece it is desired to heat. The size of the piece to be heated governs the amount of current consumed, and acts as the regulator, there being no other means of regulation employed. The receptacle may be provided with a lining of lead, if desired, and made to act as one pole. It also can be made of iron, or other metal, and made to serve in a like capacity. The negative pole in this case, would form a rest outside of the receptacle for the piece to be heated. That portion of the piece which is submerged in the bath will commence to heat as soon as it touches the bath, the circuit being closed through the anode and bath. An envelope of incandescent gas is instantly formed around the submerged portion of the metal and constitutes a voltaic arc surrounding the metal on all portions below the surface and separating it from the solution. When the workman observes that the piece has attained the proper heat, it is subjected to the forging or welding operation.

Bars of different sizes may be heated in the same bath up to the capacity of the circuit conveying the current. The passage of the current into the solution seems to transform it from a high tension and low volume to a current of large volume and low tension. Two bars may be held in contact and one receive current from the other. An incandescent gas envelope will be formed around these portions which are submerged below the surface of the solution, and the bars may be welded together in the bath by simply bringing the pieces in contact with each other.



FIGS. 1 AND 2.—PLAN AND LOGITUDINAL SECTION OF TANK.

Experiment has shown that when the working circuit is constant at 220 volts and the specific gravity of the liquid is at 1.15 and small pieces are to be heated, the size of a four penny nail, the amperage recorded will be five and the voltage will remain constant at 220, and, as the size of piece to be heated is increased the voltage will decrease and the amperage increase. In heating a piece three inches long and one inch square, the voltage will be reduced from 220 to 180, and the amperage will be increased to 98, showing that the piece governs the current required to heat it. A transformation of the current takes place in the tank when the piece is immersed, and shows a consumption of a trifle over 23 h. p. for 40 seconds for this size, when the liquid has a specific gravity of 1.15. The operator can hold the upper ends of the bars in his hand unprotected, as the current only passes through the lower portion between the rest, which form the negative terminal, and the solution, the bar taking off from the line more or less current, according to the volume required to effect the heating.

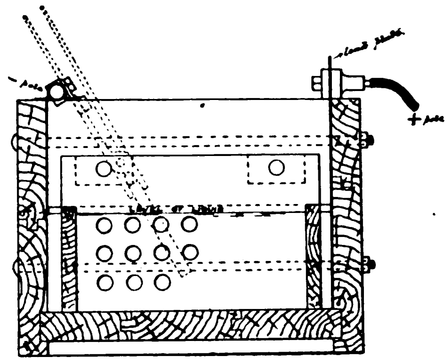


FIG. 3.—VERTICAL SECTION OF TANK.

In general practice automatic clamping devices are used which are connected to the negative pole. This pole, which is a substitute for the support, is fastened near the edge of the tank containing the liquid, and, while the workman is forging or welding one or more pieces, other pieces are being heated, the bath performing all the functions usually required about an ordinary forge.

Among the many advantages derived from the use of this system is its employment in connection with apparatus already installed for the purpose of electric lighting. A large percentage of the manufacturing establishments use an electric light plant. During the day, this apparatus, which remains idle, could be utilized for producing current sufficient to operate this liquid heating process, which can be installed without additional expense, except for the tank, wires and switch, thus affording an apparatus capable of continuous use, heating metals during the day and producing light at night.

THE THEORY AND DESIGN OF THE CLOSED COIL CONSTANT CURRENT DYNAMO.[1]—I.

BY PROF. HENRY S. CARHART.

THE speaker stated that it was not his purpose to draw any comparisons whatever between opened and closed-coil armatures; the former, he said, is entitled to that consideration which long continued and satisfactory service in public and private illumination had earned for it, but the latter is making its way into public favor, and it has certain peculiarities which make it an interesting subject for study. If he were to draw attention in this paper to comparisons between dynamos of different type, it would be between those for [illegible]t potential and those designed for constant current, both [illegible]osed-coil armatures. For in almost every particular the la[illegible] is diametrically opposite to the former.

He then called attention to a number of points of dissimilarity between the two types, assuming that the speed be constant in both cases.

THE NEUTRAL PLANE INDEPENDENT OF THE PLANE OF COMMUTATION.

By neutral plane is meant a plane passing through the axis of the armature and so situated with reference of the poles of the field magnet that when a coil of the revolving armature is carried across it the E. M. F. generated changes direction. This plane intersects the armature in a straight line, but it may broaden out more or less into a surface of small lateral dimensions.

The plane of commutation is a plane passing through the armature axis and the points of contact of the brushes on the commutator. It is the plane joining the poles of the armature considered as an electro-magnet. This latter plane, of course, shifts with the brushes, since the poles of the armature are the points at which the current enters and leaves the armature, and these are necessarily the points or surfaces of contact of the brushes with the commutator, assuming that the connections from the armature to the commutator run directly out parallel to the shaft. To state the proposition now under discussion in the form of a question, Does the neutral plane shift when the brushes are shifted forward or backward? If we were to make answer from the assumption that the resultant of two impressed magnetizations or magnetomotive forces may be obtained in the same manner as the resultant of two forces by means of the triangle of forces, we should probably conclude that the neutral plane rotates forward with a forward movement of the brushes. But experiment along several different lines shows that this conclusion is erroneous. If we were to apply to the solution of this problem the principles derived from constant potential machines we should be forced to the conclusion that, to maintain sparkless commutation at the brushes, the lead of the brushes beyond the neutral plane should be constant, since the current remains constant; and therefore that any attempt to govern for constant current by rocking the brushes must be attended by destructive sparking, unless at the same time the field is greatly modified. But these conclusions are also erroneous. We must therefore first establish the facts and then make a theory to fit them.

---

[1] Abstract of a lecture delivered before the Franklin Institute, Philadelphia, Jan. 17, 1894.

[1] Abstract of a lecture delivered before Electrical Section of the Franklin Institute Tuesday Dec. 26, 1893.

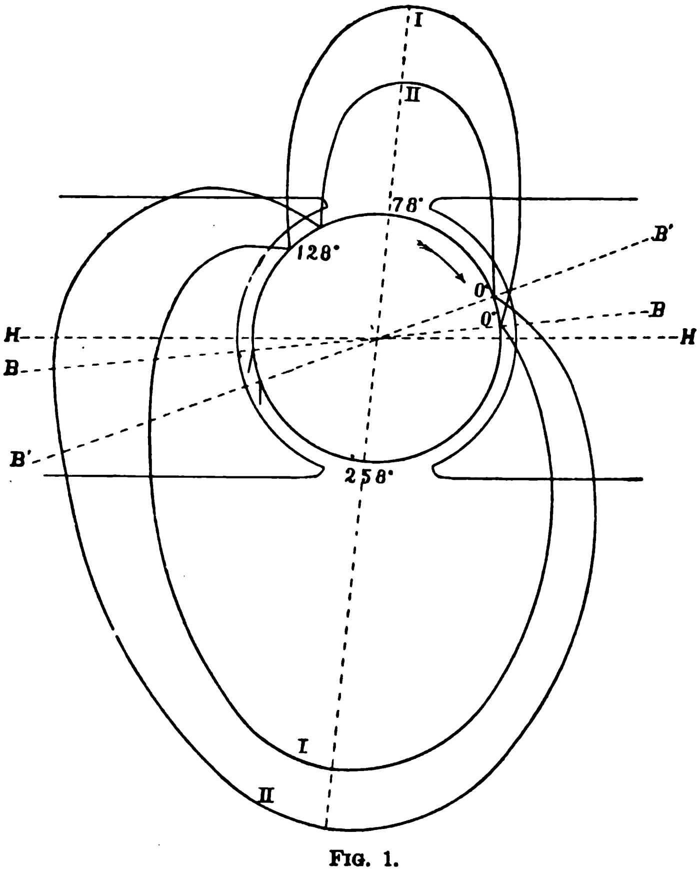

FIG. 1.

The fixed position of the neutral plane I have determined on a ten-light machine in two different ways.

First Method.—Four turns of No. 16 silk covered magnet wire were wound around the armature ring as an exploring coil. One end of this coil was soldered to a copper band or ring fastened on the commutator and insulated from it by several thicknesses of mica. The other end was soldered to a piece of brass let into a fibre collar placed around the commutator. One extra brush was fastened to one of the main brush holders and rested on the copper band. The other extra brush rested on the fibre collar and could be attached to any point of a circular scale made concentric with the commutator. A twisted cord ran from these two brushes to a telephone at some distance. When the dynamo was running, the movable brush, which rested on the fibre and made contact with the brass strip every revolution, was moved around the circle till a minimum sound was heard in the telephone. The exploring coil was then on the neutral plane at the instant when the brush made contact with the strip. Motion of the brush either way caused the sound to increase in loudness. The position of the exploring coil for minimum sound was to be found about 5 degrees in advance of the normal plane intermediate between the pole pieces; and its position did not change from full load to no load as far as could be detected by this method.

Second Method.—To the brush holders was attached an insulating ring slotted on the periphery at every ten degrees on a milling machine. It was made as nearly concentric with the commutator as possible. A third brush holder was placed in the successive slots, and the potential difference between it and one main brush was measured in its several positions. These measurements gave the integrated P. D. between the main brush and successive points on the commutator all the way round the circle and back to the starting point. This was done with no load or nearly short-circuit, with a load equivalent to three lamps, and finally with a load equivalent to nine lamps, the current being ten amperes in each case. The results in the first two cases are plotted round a circle in Fig. 1. Positive values, or those in which the potential of the third brush was higher than that of the main positive brush, are set off outside the circle in the upper part of the figure; while negative values are set off outside in the lower section of the diagram. The direction of rotation is clockwise. With no load the highest positive potential was about 78 degrees behind the positive brush. From this point it fell again, and at 128 degrees it was the same as that of the positive brush. For all the coils between 0 degrees and 128 degrees the integrated positive and negative E. M. F.'s. exactly equal each other. The neutral plane falls evidently 78 degrees behind the brush, or the brushes may be said to have a lead of 78 degrees with no increase in sparking. A negative maximum occurred at about 260 degrees and the P. D. between the positive and negative maxima was 644 volts. The same P. D. was found by direct measurement when two extra brushes were set at these points.

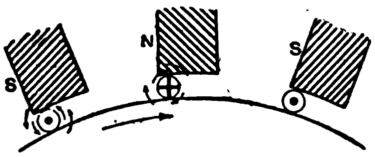
With a load equivalent to three lamps the brushes were rocked back 15 degrees to bring the current to ten amperes. Hence the zero of this curve begins 15 degrees back from the zero of the first curve. Again the observations are plotted and the positive maximum falls at the same place on the circle and therefore at the same place on the commutator. The two maximum points are about 65 degrees and 245 degrees from the positive brush and the two potential differences are 163 and 456 volts. Their sum this time is 624 volts, a little less than with no load. With the highest load carried the brushes were rocked backward about 50 degrees further and the lead was then about 15 degrees. The extreme P. D. obtainable this time did not exceed 600 volts. So far as can be discovered from these curves the neutral plane remains fixed, while the brushes move round the commutator to adjust to a constant current. I find no evidence in them that the forward movement of the brushes to control the current causes the neutral plane to move with them. As the brushes advance with a diminishing external load they put between them and the neutral plane an increasing number of armature turns generating counter E. M. F.; and it is a striking fact that, when the field coils are not cut out, the back turns on the armature cut down the P. D. between the brushes not by a counter magnetomotive force apparently, but by counter electromotive force; for the maximum P. D. to be found on the commutator is no less on no load than on full load, showing that at least as many lines of force traverse the armature core with the brushes far forward and with many back armature turns as with the brushes in the position for the maximum load and with the back turns reduced to a minimum.

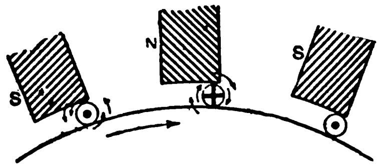
THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.—VI.

BY PROF. GEORGE FORBES.

MR. GISBERT KAPP said there was one point which struck him on reading the Paper for the first time, where the author was discussing the merits of the number of phases, whether they should have a single phase or two or three phases. When he (Mr. Kapp) was in America in the summer he had a long talk with Prof. Thomson upon this subject. He was very hazy at the time, he must confess, and Prof. Thomson tried to convince him that three phases would require less copper than two. He could not see it then, but he had since studied it, and read all that Dobrowolski and others had written on the subject, and at last he could see light. The result of his investigation was this: Suppose they found the copper in the line weighed 100 tons when a continuous current was employed. If they now worked a different line with the same length and the same efficiency of transmission and the same stress on the insulators with an alternating current, they would double the copper, which would now weigh 200 tons. If they used two phases with four wires they would again require 200 tons; but if they thought to save copper by using only three wires and working two-phases they would require 290 tons, so that the system which Prof. Forbes recommended as the most economical in copper was actually the worst. If they now had three wires, and worked at three-phases, they would use 150 tons only. Two-phase working with three wires was out of the competition altogether; it was too expensive. As regards the motors, he had again the misfortune to differ from Prof. Forbes. The latter thought the low-frequency motor would be more efficient, and at the end of his Paper a calculation was given to show that the losses in the high frequency motor were 42 per cent. greater than in the low frequency. He quite agreed with the 42 per cent., but he was afraid Prof. Forbes had overlooked the fact that with the high frequency they would have to supply two and a half times the electromotive force, and it would give two and a half times the power, and, consequently, what appeared to be an increase in the loss of 42 per cent. became actually a gain of 33 per cent., so that on his own showing the high frequency was the more efficient. One reason which Prof. Forbes has given for the use of low frequency, and which had appealed to him (Mr. Kapp) very strongly, was that you could make a synchronizing motor out of any dynamo. If they wanted to rig up a motor quickly they could go and buy a dynamo and set it to work. But when he began to consider what had to be done he saw that it was not so simple. They had to put on two contact rings to begin with. Dynamos were cut very fine nowadays; makers did not give extra room for fancy fittings. Therefore they had to send it out to be fitted with these things by a maker. Supposing they had done this, how were they going to start it? Being a single-phase motor, it would not start by itself, and they must put down a little Tesla motor, or some other, to start it. And if they did that they might as well use the Tesla motor a little larger and run their factory from it. He would like to point out that single and multiphase alternate-current motors were on the market and were very good. The only reason that the impression prevailed in England that they were not to be had, that they were not reliable, and only experimental, was that they placed too much credit on what appeared in the electrical papers. He was afraid the papers were treating them rather badly in this respect. It was the fashion amongst them to cry down multiphase and alternate-current work. He could quite symphathize with the editors; it was an unfortunate thing that they had to take up new subjects and study them in order to write intelligently about them. The ordinary alternating current was bad enough, but when you came to three phases it was really too bad. But they should not cry down these things; let them state what the facts were. He had tested such a motor made by the Oerlikon Company, with the following results: the machine gave on the brake 862 watts, and it ran at a speed of 1,800. The frequency varied from 60 to 67; the commercial efficiency was 60 per cent.; the power factor was 74 per cent.; and at starting the current to produce a torque equal to that at the full output of 1¼ h. p. was 2¼ times the normal working current. It was rather inconvenient to have such a large current at starting, but by a very ingenious arrangement, now used all over the Continent, the mains did not feel this large current. There was an auto-transformer with a switch handle, which, at the expense of pressure, gave the extra current which went into the motors, and it worked beautifully. The weight of that machine was under 1cwt. per horse-power. There seemed to him to be very strong reasons against the adoption of low frequencies as regards motors, and perhaps not so great, but still sufficient, reasons as regards the transformers; one very strong reason was the cost of the alternator. He had studied the design of Prof. Forbes's alternator very carefully, and he might say at once that he was very pleased to be able to agree with him that it was about the best machine that could be made for the job.

Prof. Silvanus Thompson said that the Paper bristled with points, but he would confine his remarks to one or two. In the first place some rules concerning parallel working were given, or rather some remarks were made about the knowledge, or want of knowledge, upon that which constituted the successful design of machines for working in parallel. Prof. Forbes said: "The rules which govern the construction of machines which shall work well in parallel are not very clearly understood. The only fact which has been perfectly established in practice is that the lower the frequency the more efficient and sure is the parallel working." He, too, felt disposed to dispute this point. He would not dwell upon it—he simply disputed it; it had not yet been established; it might be true, but it had not been established. But he did venture to think that this was not the only fact bearing upon the question of the construction or the design of machines for parallel running. In the first place they knew perfectly well that machines would not run well in parallel if they had weak field magnets, if they had armatures that, with the output that the machine was designed for, would perturb or interfere with the magnetism of the field in any serious way. Further, they knew that they did not get easy working between two alternators of distincly different types. In this case, if the two alternators were so designed, whether in the placing of their coils, or the shape of their pole-pieces, or the relative positions of coil and pole-pieces, so that the curves of their induction were widely different, one giving a form nearly like a sine curve, and the other giving a curve like a saw-tooth curve, they would not run in parallel. These were points that really were known, and bore largely on the question of design. Further, he would like to point out that they sometimes spoke of the self-induction in the armature, and of the reaction of the armature, as though they were the same sort of thing. There was no doubt whatever that an armature which had no iron in it, or in close proximity to it, would have less self-induction and armature reaction than an armature that had much iron in it, and that iron in close proximity to the coils. But they might have an armature which had much self-induction without necessarily very much armature reaction. It depended upon how the iron was disposed near the armature coils with respect to the approach to the polar parts, and the thing which was disastrous in the design of an alternator for these purposes was the putting of iron into the armature in such a way that the iron acted violently on the magnetism, and pulled it about so that the field became an unsteady one. All this, of course, was contained in those wonderful equations on the action of alternate-current machines which Dr. Hopkinson published about 1884. He (Prof. Thompson) was perfectly well aware that the whole theory of alternate working and parallel running could be dug up from those equations. But it was more to the point if they inquired what was the physical action which went on and made it easy or dificult for two machines to run in parallel when they were placed on the same circuit; and the physical effect was really easy to follow out if described by means of a diagram. If they took one of the ordinary types of alternator, say, for example, the Westinghouse (see diagram). Suppose the armature core to be rotating right-handedly, and they had the wires on the outside, the tendency would be to generate currents which would come toward them as the wire was passing the S pole, and to go away from them as the wire was passing the N pole. That was to say, the electromotive forces, everything being supposed to be symmetrical, would be at their maxima in those coils, and would die away to nothing exactly half-way between the poles. Suppose they had two such machines, exactly alike in phase with one another. Their electromotive forces were at a maximum at that particular instant, and if there was no lag in the current, no self-induction, they would have the currents also at a maximum at the particular point. Now, suppose they had those two machines coupled together in parallel, the electromotive forces were equal if other things were equal, and there was no tendency for one machine to send a current through the other one either way. Now suppose one was a little behind and the other a little ahead, then the electromotive forces would not necessarily be equal. The consequence would be that the current produced by the two through one another, would throw a load on the leading machine tending to bring it back, and a load tending to bring up the lagging machine. But now suppose that the current in the wires was capable, by reason of the disposition of the iron or anything else, of producing considerable reaction. Now for the receding current, the tendency was to exercise a magnetizing force around it which would strengthen the field in front of it, and weaken it behind. As a matter of fact, the question of strengthening the field in front of it, or weakening the field behind it, strengthening the field as a whole, depended upon whether the strengthening or weakening was a maximum when the coil was in front of the pole of the alternator or not. If the maximum was reached when the wire was behind the middle position it considerably strengthened the field, but if the maximum occurred when the wire was in front of the middle position it would weaken the field. The one that was ahead of the other would weaken its field, while the other one would strengthen its field. These two reactions, the one of strengthening, the other of weakening, precisely tended to defeat the tendency of the two machines to get back into parallel; that was to say, the back armature reaction would of itself tend to prevent the synchronism to parallel.





THE TELEPHONE IN GERMANY.

According to the *Zeitschrift für Electrotechnik*, the number of telephone stations in Germany, which was 1,504 in 1881, had increased at the beginning of this year to 68,558, of which Berlin had 17,424, with over 20,400 miles of lines. The interurban service is also increasing rapidly, and there were at the beginning of the year 316 long-distance telephones, with 14,280 miles of line, the longest direct line being that between Berlin and Breslau, nearly 200 miles.

LEGAL NOTES.

EDISON ELECTRIC LIGHT COMPANY v. DAVIS ELECTRICAL WORKS IN THE COURT OF APPEALS.—REPAIR OF LAMPS.

IT will be remembered that a few weeks ago Judge Colt, of the United States Circuit Court, District of Massachusetts, granted to the Edison Company an injunction against the Davis Electrical Works, of Springfield, Mass., for repairing incandescent lamps. The Davis Company at once appealed from this decision, and on Thursday, the 18th inst., a hearing was given before the United States Circuit Court of Appeals, District of Massachusetts, before Judges Putnam, Nelson and Webb. Messrs. Fish and Richardson acting for the plaintiffs, and ex-Judge Lowell of Boston and Mr. J. L. Roberts of Boston, for the defendants.

In opening the case Mr. ROBERTS, referred to the argument of the defendants, in saying that the cheapness of the lamp precluded it from any necessity for repairs, and that it was intended for the scrap heap when the carbon burned out. He combated this idea and said any company had a perfect right to repair its lamps, as they might and did burn out frequently before the guaranteed number of hours had expired. He then proceeded to ridicule the idea that the Edison Company's claim that when the Davis Company opened a lamp for repairs they destroyed the Edison vacuum, or vacuous space. The vacuous space was simply the shell of the lamp, containing nothing, and he did not think the Edison Company could claim the air, though they appeared to claim everything else. He stated that it was not true, when the defendants claimed that after the Davis Company repaired a lamp, they had a *new vacuum* (such a claim was ridiculous) a new globe and a new carbon. Not a piece of glass (saving the little tip on the bottom of the lamp) is taken away and not a piece is added, We have, he said, everything in the lamp to be repaired that was there originally, except the carbon,—the leading-in wires, the copper wires, the cap, the glass, everything is just as it was, except that we put in a new carbon to replace the one burned out. Judge Colt had allowed in his decision, that if the lamp were opened from the socket end and a new carbon put in, as in the original Sawyer-Man lamp, it would not infringe, and he asked the Court what the difference was if the Davis Company opened the lamp at the other end and put in a new carbon. Mr. Roberts, then, with the aid of a regular glass-blower's bench and the assistance of a workman, showed the Judges the precise operation of repairing a lamp as done by the Davis Company, and also by way of contrast the extra labor necessary in making a new lamp. He then went on to cite cases where the Courts had allowed parts of machinery to be repaired, as in ploughs where the tips wear out, planing machines where the cutters wear out, and others.

MR. FISH, then argued for the plaintiffs and commenced by saying that it was not possible for the Judges to judge intelligently without fuller knowledge of the Edison patent, and the state of the art prior to Edison's discovery. He claimed that the Edison invention was radically new, and many scientists had said that it was impossible to subdivide the electric light, until Edison showed them how. He then went on to explain the nature of Edison's lamp, the multiple arc system of distribution, Sawyer-Man experiments with carbons of rod, the introduction of nitrogen, the disintegration of the carbons, the discovery of Edison that a high resistance filament of small radiating surface was necessary, the great discovery of the air-washing effect, and all the necessary steps leading up to Edison's invention. "During all these years," he said, "no one ever tried to repair lamps; that process did not commence until after suits were commenced against infringers, and it was done simply to evade the patent. The Edison lamp distinctly took the place of the old lamps which were made to be repaired, and was made *as a whole*, each part having a definite relation to the other part, and was distinctly made in such a manner, that it was intended to be thrown away, after being burned up, and no one ever attempted to do anything else until this litigation arose. Mr. Fish also then cited cases where repairs were lawful, but claimed that these machines were so made, that it was intended from the first that the worn out parts should be repaired, and were totally distinct from the case in point, whereas the incandescent lamp was made as a whole and not intended for repair. In repairing the incandescent lamps, he maintained that the combination of the second claim of the Edison patent was broken;—the vacuous space disappeared, there was left no vacuum, no all-glass receiver, no carbons, nothing but the leading-in-wires, and he claimed the lamp when repaired was really and practically a new lamp. "How," he said, "is this like restoring knives, or repairing broken gears, or burned out grates in furnaces." "No," he claimed, "it is totally different." The question is "Is the identity of the machine maintained?" Then he went on to explain to the Court that even the voltage of the lamp repaired might be changed, nay, must be changed, as he claimed that it was impossible to replace a carbon of exactly the same voltage as the one originally in the lamp. He also claimed that the cost of repairing lamps was just about the same as the cost of manufacturing new lamps, and that therefore the repairing of lamps was entirely unnecessary. Mr. Fish then went on to explain to the Court that the plaintiffs were under contract with more than ninety licensees, who had the exclusive right to sell lamps in certain territories, and whom they were bound to protect. "The patent may expire in November, 1894," he said. "It will expire then as the law now stands, and in these last days of the life of the patent," he prayed that the injunction be granted, on the ground that the defendants by their claims were actually enjoying the protection of the Courts, which had maintained the Edison patent, and prevented them (the defendants) from making new lamps.

EX-JUDGE LOWELL, afterwards addressed the Court, and disputed the claim made by Mr. Fish that no repairs were made in lamps until after the commencement of litigation. The Davis Company did both, but stopped making new lamps, very soon after the first suits for infringement were brought, without the action of the Courts, as they were convinced that they would infringe the Edison patent, by making new lamps, as had been decided by the Courts. It was not a question of ease or difficulty of manufacture, or cost of repairing as compared with the manufacture of new lamps; it was whether the carbon was temporary or not. In a combination patent, every element is of equal value, he claimed, and if anyone could get along without one element of the combination, he would not infringe the combination patent. He claimed that preliminary injunctions were just as bad as final injunctions, in their effect on the company enjoined, and are sometimes refused for the same reason that Mr. Fish advanced for the granting of the injunction, namely, for the reason that the patent is about to expire. Judge Lowell then brought up an interesting point of law as to whether the Court of Appeals could reverse the decision of the lower Court, and the Judges allowed the plaintiffs ten days in which to file a brief relating to this point.

TERMS OF THE NOVAK STAY OF INJUNCTION.—EDISON ELECTRIC LIGHT CO. vs. WARING ELECTRIC CO.

THE terms of the stay recently granted by Judge Shipman in the "Novak" lamp case run as follows:

"The operation of the injunction shall be stayed until the 23d of January, or on such a day thereafter as the court of appeals shall first assemble and that this stay shall then "ipso facto" terminate unless the defendants have perfected their appeal and said case is ready to be called for argument in its due order as a preferred case on the calendar on that day and the defendants then stand ready to argue the same. In which case this stay shall continue until said appeal is decided by the appellate court. The above stay is granted on the condition that the defendants on or before Tuesday, January 16, 1894, file a good and sufficient bond in the sum of $10,000 with satisfactory securities to pay to the complainants any damages or profits to which they may be entitled because of the continuance of the manufacture by the defendants of the lamps alleged to infringe said patents in suit during the period covered by said stay."

A special dispatch of Jan. 18 from Hartford, Conn., says:—The Waring Electric Company of Manchester has filed a bond of $10,000, pending the appeal in the suit of the Edison Electric Light Company and others. The bond was executed by President Chapman. Clerk Marvin of the United States Court forwarded to Clerk Shields of the United States Circuit Court of Appeals, New York, all the papers, exhibits, etc., in the suit. The case will be argued Jan. 23.

EDISON ELECTRIC LIGHT CO. vs. E. G. BERNARD CO.—EDISON CIRCUIT PATENT LITIGATION.

In the United States Circuit Court at Albany, last week, Judge Coxe heard argument of counsel for and against the motion for a preliminary injunction in the action of the Edison Electric Light Company against the E. G. Bernard Company of Troy, N. Y., for infringement of the Edison feeder patent of 1882, in the use of a system of electrical distribution in the plant being installed at the Watervliet arsenal. Argument was concluded Thursday and decision was reserved. Judge Coxe also refused to issue a restraining order against the defendants in a suit between the same parties under several other patents, and gave the defendants three weeks in which to file answering affidavits. George A. Mosher of Troy appeared as attorney for the Bernard Company. The last case is a suit over an alleged infringement of the Bernard Company on six or seven electric lighting arrangements which the Edison Company claims to have originated.

The most important dispute is under what is known as the three-wire patent. The Edison Company petitioned the court to grant an order restraining the Bernard Company from using this patent. Mr. Bernard stated that the arrangement is under the patent of the Siemens & Halske Company of Berlin which antedates the Edison patents from two to five years. Judge Coxe has as yet rendered no decision in the matter of the request for a preliminary injunction against the Bernard Company from using the Edison feeder patent of 1882.

PROF. ROWLAND WINS HIS SUIT AGAINST THE CATARACT CONSTRUCTION CO.

THE suit of Prof. H. A. Rowland against the Cataract Construction Co. for $30,000, as a fee for his services in connection with expert work preliminary to the selection of plans and apparatus for the Niagara transmission was brought to a close on Jan. 20. Prof. Rowland's original bill was for $10,000. The company sent him a check for $3,500. He then brought suit for $30,000, based on a per diem charge of $150. The jury gave him a verdict for $9,000, making $5,500 in addition to the sum already paid. The case will be appealed. It was heard before Judge Shipman, with John S. Wise for the plaintiff and Joseph H. Choate for defendant. Many distinguished witnesses were called on both sides, including Frank J. Sprague, Dr. Louis Duncan, Wm. Stanley, Jr., Prof. George Forbes, Dr. W. W. Jaques, Prof. Barker, Dr. Coleman Sellers. The case attracted a good deal of attention. Mr. Choate tried without much success to belittle Prof. Rowland, but made the most of a remark in a private letter of the plaintiff that he was one of the first physicists in the world. It came out that Lord Kelvin and Dr. Hopkinson had only received $2,500 each for their services.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the meeting of the Council of the Institute held January 17, the following associate members were elected:

Adams, Comfort A., Jr., Instructor in Electrical Engineering, Harvard University, 21 Stoughton Hall, Cambridge, Mass.; Bethell, U. N., Acting General Manager, The Metropolitan Telephone & Telegraph Co , 18 Cortlandt st., N. Y. City; Broadnax, Francis, Engineer, Safety Insulated Wire and Cable Co., 50 Broadway, New York City; Broich, Joseph, Superintendent and Electrician, with F. Pearce, 418 8th ave., Brooklyn, N. Y.; Ende, Sigfried H., Colonnade Hotel, 39 Lafayette Place, New York City; Flanagan, Thomas Francis, Supt. and Electrician, Portsmouth Gas Light Co., Portsmouth, N. H.; Flint, Bertram P., Electrical and Mechanical Engineer, with Chas. H. Davis, 120 Broadway, New York City; Knox, James Mason, Student in Electrical Engineering, Columbia College, School of Mines, New York City; Meredith, Wynn, Asst. Superintendent Operating, Electrical Dept., Midwinter Fair, San Francisco, Cal.; Osterberg, Max, Student in Electrical Engineering, Columbia College, 232 East 62d st., New York City; Selden, R. L., Jr., Deep River, Conn.; Sever, George F., Instructor in Electrical Engineering, Columbia College, 121 East 30th st., New York City; Smith, Charles Henry, Assistant Electrician, South Eastern Tariff Association, Atlanta, Ga.; Sprout, Sidney, Electrical Department, Midwinter Fair, San Francisco, Cal.; Wardlaw, George A., Assistant Engineer, People's Light and Power Co., Doolittle House, Oswego, N. Y. Total 15.

The following associate members were transferred to full membership: Emmet, W. L. R., Electrical Engineer, General Electric Co., New York City; Keith, Nathaniel S., Electrical Engineer, San Francisco, Cal.; Adams, Alton D., Worcester, Mass.; McCluer, C. E., Supt. First District, Southern Bell Telephone and Telegraph Co., Richmond, Va.; Jackson, J. P. Assistant Professor of Electrical Engineering, Penn. State College, State College, Pa. Total 5.

A report was made from Dr. F. B. Herzog, chairman of the Committee on revision of the rules recommending a few minor changes in the rules governing elections. Owing to the lateness of the hour, its consideration went over to the next meeting.

During the evening session of the 17th, Dr. Louis Bell presented an admirable paper on "The Practical Properties of Polyphase Apparatus," which was discussed by Messrs. Stanley, Steinmetz, Mailloux and others. The following report was presented by the Committee on Units and Standards:

Your Committee on "Units and Standards" begs to recommend to the Institute the provisional adoption of :—

The term "gilbert" for the C. G. S. unit of magnetomotive force, the same being produced by 0.7958 ampere turn approximately.

The term "weber" for the C. G. S. magnetic unit of flux sometimes described as the C. G. S line of flux.

The term "oersted" for the C. G. S. unit of reluctance

The term "gauss" for the C. G. S. unit of flux density, or one weber per normal square centimetre.

The Committee, it will be remembered, in its previous report, dated June 20, 1891, advocated that the above terms should be accorded to magnitudes in conformity with the "practical" electromagnetic system, and therefore following in natural order and extension from the volt, ohm, ampere and other units in universal use.

As, however, so important a series of new unit magnitudes could only meet with general recognition and favor under the authorization of an International Electrical Congress, which authorization has been withheld at the recent Congress at Chicago, and since objections have been raised to those magnitudes, your Committee considers that the urgent need for names specifying the principal quantities dealt with in magnetic circuits can best be met with general favor, by adopting for those names the fundamental unit magnitudes of the international C. G. S. system after the precedents already established in the cases of the C. G. S. units of force and work, entitled respectively the "dyne" and "erg."

F. B. Crocker, W. E. Geyer, G. A. Hamilton ; A. E. Kennelly, Chairman.

The report of the Committee on being put to vote, was not adopted.

ANNUAL MEETING OF THE NORTHWESTERN ELECTRICAL ASSOCIATION.

THE annual meeting of the Northwestern Electrical Association was held at Milwaukee on January 17 and following days. A brief but excellent programme of papers was discussed. The names of those in attendance are as follows :

Herman Andrae, L. V. Gibbs. M. H. Johnson, W. Goltz. Mayor H. C. Koch, H. D. Goodwin, O. D. Kleinsteuber, James Motley, S. G. Coleman, R F. Kountz, M. L. Stevenson, O. M. Rau, Milwaukee, Wis.; F. Overbaugh, H. D. Latimer. Geo. Mayo, W. D. Ball. D. S Terry, A. C. Bunce, W. J. Ferris, W. C. Wheaton, W. W. Low, S. F. B. Morse, G. S. Whyte, Fred. De Land, W Forman Collins, F. N. Boyer, P. J. McFadden, Chicago: W. B. Baker, J. P. Lord, Waupaca, Wis.; Pliny Norcross, Janesville, Wis.; C. C. Paige, Oshkosh, Wis.; E. L. Dubell, Sheboygan, Wis ; H C. Thom, Madison, Wis.; John Shulte, Manitowoc, Wis.; John Wiley, Hancock, Wis.; Carroll Collins, Green Bay, Wis.; M. L. Stevenson, Cleveland, Ohio; W. H. Thorpe, Beaver Dam; J. Earle, Kaukauna, Wis ; T. G. Grier, J. A. Berkley, Little Falls, Minnesota; C. A. Spencer, Centralia, Wis., G. L. Cole, Beloit, Wis.: H. Amundson, La Crosse, Wis.; E. Engrebreton, Whitewater, Wis.; M. A. Burt, Baraboo, Wis.; C. D. Johnson, Tomah, Wis.; T. F. Grover, Wawautosa, Wis.; J. H. Trever, Antigo, Wis.; J. A. Andrews, Hudson, Wis.: G. F. Merrill, Ashland, Wis.; D. C. Jackson, Madison, Wis.; Geo. Grimm, Jefferson, Wis.; E. K. Patton, Boston.

The officers elected for the current year are as follows :

President, C. C. Paige; 1st vice-president. W. B. Baker; 2d vice-president, E. L. Debell; secretary, H. C. Thom; treasurer, G. F. Merrill; directors, W. Goltz, Pliny Norcross, John Shulte.

THE ELECTRICAL WORKERS' LECTURES.

THE UNIVERSITY EXTENSION LECTURES on Electricity arranged and undertaken by the Electrical Workers of this city, under the supervision of Columbia College, have proved an instantaneous success. The course opened at Cooper Union on Monday, January 15, when Mr. C. O Mailloux delivered an excellent lecture on "Batteries," illustrated with practical batteries and examples. The attendance cannot have fallen far short of 500. A large number of persons were unable to get into the hall, and standing room was not to be had. The lecture was followed with the most intelligent interest and with a ready appreciation on the part of the audience of its important points. The lecture to follow on Monday evening (Jan. 22) by Dr. Louis Bell on "Alternating Current Dynamos and Motors" promises to prove not less attractive and instructive. The trade organization which has thus lent its powerful support to educational work among its own members and the public is entitled to all praise.

THE FRANKLIN ELECTRICAL SOCIETY.

A RECEPTION and banquet were given by the Franklin Electrical Society, on Saturday evening, Jan. 6, at the Columbia, this city, in commemoration of Benjamin Franklin. The hall was decorated with the Society's colors, and all those who were present, voted it a great success. Mr. W. W. Ker, toast master, introduced the various speakers of the evening, among whom were Mr. E. V. Lallier, president, Mr. Max Mayer and Mr. Arthur Hammerschlag. Mr. Newton Harrison read a very able and interesting "Eulogy on Benjamin Franklin"; and Mr. Louis Wasself entertained the guests with an amusing paper on "Electrical Terms and Phases."

REVIVAL OF THE DRAWBAUGH TELEPHONE.

AN ordinance has been introduced in the Philadelphia Common Council granting permission to the Drawbaugh Telephone and Telegraph Company of Philadelphia, which was recently organized with a capital stock of $3,000,000, to construct and operate a system of wires and cables within the city limits. This action is the beginning of an effort to introduce a rival telephone service upon the expiration on January 30, of the Bell Company receiver patents.

ERRATUM.

IN the article entitled "The Telephone Patent Litigation," begun in our issue of Jan. 17, an error crept in regarding the number of the Phelps patent (page 45, eighteen lines from the top of first column). The number should read 220,209, instead of 222,201, which refers to the Phelps support switch patent.

LETTERS TO THE EDITOR.

ELECTRIC LIGHTING AND INSURANCE RATES.

The writer has been engaged for some time in ascertaining how many fires have been charged against the electric lighting interest in this city since the beginning of the filing of reports as to the cause and origin of fires, and having ascertained that electric lighting has had less fires assigned to it than any other, he deemed that it might be of interest to the readers of THE ELECTRICAL ENGINEER to give a list of fires as charged to the different methods of illumination, viz., kerosene oil, gas and electricity; and also a list of those fires charged against matches and general causes, making five specific headings against which fires are charged in this city.

	1888	1889	1890	1891	1892	1893
Kerosene Oil.....	181	174	144	248	294	371
Gas..............	62	110	116	151	200	194
Matches..........	31	65	90	116	193	187
Electric.........	9	33	23	20	34	31
General	1075	1472	1650	1849	2118	2103

In looking over the list you will notice that kerosene heads the list (outside of the general causes), gas coming second, matches third, and electricity fourth. The writer would invite your attention and that of your readers to the fact that when the cause and origin of a fire is attributed to kerosene oil or gas, 99 per cent. of the charges are correct, inasmuch as it is possible to show that kerosene oil or gas have caused the fires for which they are charged, as any fire originating from either of these causes is so evident that no doubt is left in the minds of the Fire Patrol or Fire Department as to the origin. In the case of matches there is, we must admit, considerable guess work, and quite a number of fires are charged to matches that occur from unknown causes; but as relating to the charges against electric lighting as having been the origin of fire in any particular case, it is very rarely indeed that it can be proved indisputably that it was due to electricity. The writer knows of several instances within the past year, where fires have been attributed to electric light wires where the origin of the fire very plainly indicated that it arose from improperly placed [illegible] wires."

About a year ago it was brought to the attention of the writer that the insurance people intended or desired to issue a ruling that on all buildings using electric lighting as a means of illumination an extra premium of 25c. on each $100 of insurance should and would be charged over and above their regular rates; that is, if the party were paying 50 cents per $100 he would be charged 75 cents if he were to use electric lighting as a means of illumination. The basis upon which the insurance people claim to have arrived at this decision was the fact that for some time past they had had a large number of heavy losses on a certain class of risks, that had theretofore not caused them losses, and that therefore they concluded that the cause and origin of fire must be from electric light wires and apparatus; and consequently they argue that all electric light privileges should be saddled with a 25-cent additional rate. It is very doubtful whether this rule will ever be enforced, as it will be almost impossible for the insurance interests in any way consistently to show that electric lighting has been the cause of any great losses, and those losses that have been sustained the insurance people are to be partially blamed for, as well as the electric lighting people. I make this assertion on the fact that the insurance people have not properly looked after their own interests, or in other words, they have not retained properly instructed and experienced inspectors at remunerative salaries and thereby insured their own insurance. The writer takes the stand that of all people, insurance companies should believe in insurance, and show their belief by employing experienced and practical men; but if they expect to hire experienced men for the munificent salary of $100 per month, to go out through the country and dictate rules and regulations to men who are capable and are in fact drawing salaries of from $200 to $500 per month, then the insurance people show their weakness, and it is owing to this weakness that they, possibly, and I might say probably, have met with a great many losses that they would not have met with if they had taken hold of the subject in a proper and consistent manner.

It is but fair to state, however, that the insurance people were led to believe from the beginning, by the people controlling the electric lighting industries in this country, that electricity was absolutely safe, no qualifying remarks being made in a great many cases by well known representatives of the leading companies, that there was a difference and distinction between good and bad work. As a great many of us know from past experiene, agents of the large companies sold a great many of their plants by stating that anyone could manage and install electric light apparatus and lights, and that there was absolutely no danger from fire; and further digressed from the truth by stating that incandescent lamps gave off *no* heat, not even qualifying this by saying, no dangerous amount of heat.

One of the troubles that did, and does still, exist between the insurance and electric lighting interests, is the lack of harmony in rulings made by the insurance inspectors. It is impossible, as we can readily understand, to formulate a set of rules that will apply in all cases, but it is possible on the part of the insurance people, and also on the part of the electric light people, to have the work looked after by experienced and intelligent men, who can come together so that the interests, instead of clashing, will harmonize; and it is as absolutely essential for the insurance interests to cultivate harmony as it is for the electric light people, and in fact, I think the writer is safe in predicting that if the insurance people would cultivate it to a greater extent with responsible electric light contracting firms and companies, it would be of great advantage to their interests in the near future, inasmuch as there is no question that electric light as a means and method of illumination, in 99 cases out of 100, is far safer, when properly installed and relied upon to the entire omission of all other methods of illumination, than any other method known at the present day.

PHOENIX.

NEW YORK, JAN. 19, 1894.

OBITUARY.

GEORGE BARTLETT PRESCOTT.

WE regret to announce the death of Mr. G. B. Prescott in this city at the age of 64. He was the son of Mark Hollis and Priscilla (Bartlett) Prescott, and was born in Kingston, N. H., September 16, 1830. He came of old fashioned New England stock on both sides. During his boyhood, the family removed from Kingston, successively locating in Plaistow, Haverhill and other places, and finally in Portland, Me., where the elder Prescott became engaged in mercantile business. It was in this city that young Prescott completed his studies. After leaving school in 1850, he engaged in the telegraphic business as an operator, and was employed in 1850 and 1851 in the Boston office of the Merchants' Line, which was then working the Bain chemical system between that city and New York. Soon afterwards he entered the service of the Commercial or "House" line in the same city, where his marked ability as an operator and electrician soon raised him to the position of superintendent of that line, and also of the local system known as the "Marine Lines" extending from Boston to Cape Cod and Cape Ann. In 1859, a general consolidation of the competing telegraph lines in New England occurred, after which Mr. Presscott was appointed to the superintendency of a district comprising most of the lines in western New England, with headquarters at Springfield. Before his removal from Boston, Mr. Prescott had contributed to the *Commercial Bulletin* of that city, a series of articles descriptive of the various systems of telegraphy then in use. These attracted considerable attention, and with other kindred matter were afterwards published in book form by Ticknor & Fields, in 1860, meeting with such success that a second and enlarged edition was called for within a few years.

In the course of the controversy respecting the proposed establishment of a government telegraph, which raged with much vehemence in 1868-69, Mr. Prescott took a prominent part in opposition to the scheme. One of his statistical articles published in a local newspaper presented his views of the matter in such a forcible way that the attention of President William Orton was attracted by it, which led to the removal of the author to New York, and to his employment in the general office of the Western Union Company, in more extended services of the same character. When the office of Electrician of the company was established, Mr. Prescott was chosen to fill the position.

Mr. Prescott was married December 9, 1857, to Eliza C., daughter of Israel W. Parsons of Springfield, Mass., a descendant of the celebrated Governor Wadsworth of Connecticut, by whose orders the Colonial charter was spirited away, just as the usurper Andros was about to seize it, and hidden in the hollow of the historic tree familiar to schoolboy students as the Charter Oak.

Mr. Prescott was the author of a number of works on telegraphy and allied subjects, among the best known of which are perhaps his "History, Theory and Practice of the Electric Telegraph," 1860; "Electricity and the Electric Telegraph," 1876; "Speaking Telephone and Talking Phonograph," 1878; and "Dynamo Electric Machines," most of which have passed through several editions. Though Mr. Prescott's works have achieved a somewhat wide popularity, their excellence has been due in a much greater measure to his skill and industry as a compiler, than to any features of marked originality either in subject or treatment which may be said to have characterized them.

DEATH OF HEINRICH HERTZ.

WE have received, as we go to press, the news of the death of Prof. Heinrich Hertz, at Bonn, at the early age of 36. This news of his death will be received with profound sorrow and regret by American physicists and electricians.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 2, 1894

Accumulators :—

Secondary Battery, W. C. Lockwood, New York, 512,253. Filed Aug. 6, 1892.

The electrodes are made by depositing metallic pins in a spongy state from a solution of chloride of sodium and chloride of tin by electrolytic action.

Alarms and Signals :—

Electric Alarm for Cane Feeders, A. F. Slangerup, New Orleans, La., 511,866. Filed Apl 28, 1893.

Electrically Controlled Railway Signal, F. McBrien, Newark, N. J., 512,050. Filed July 27, 1893.

An electrical block system for steam railways.

Electrically Controlled Railway Signal, F. McBrien, Newark, N. J., 512,051. Filed Sept. 25, 1893.

Similar to No. 512,050.

Electrically Controlled Railway Signal, J. Wayland, Newark, N. J., 512,077. Filed Oct. 5, 1893.

An electric block system for steam railways.

Electric Call, P. M. Randall, Concord, N. H., 512,217. Filed May 6, 1893.

Conductors, Conduits and Insulators :—

Electric Connection, H. Sanche, Detroit, Mich. Reissue, 11.398. Filed June 24, 1890.

Consists of a terminal piece for each wire and a turn buckle connecting the two terminal pieces.

Electrical Connection, H. Sanche, Detroit, Mich. Reissue, 11,397. Filed June 24, 1890.

Consists of a binding post having a number of terminal clamps and a jam nut holding them all together.

Section Insulator, H. M. Brockbank, Brooklyn, N. Y., 511,928. Filed Aug. 21, 1893.

Employs an insulating member separating the conducting members, and a conductor from each of the latter extending along a surface of the insulating member.

Wire Covering Machine, W. H. Avis, Toronto, Can., 512,146. Filed June 7, 1893.

Distribution :—

Storage Battery System of Distribution, J. Trumpy, Hagen, Germany, 511,821. Filed Aug. 1, 1893.

Has for its object to maintain a constant potential between the terminals so as to secure a uniform action of the translating devices in the circuits.

Storage Battery System of Distribution, J. Trumpy, Hagen, Germany, 511,822. Filed Aug. 1, 1893.

Provides automatic means for including a greater or less number of cells in the circuit as circumstances demand.

Electric Circuit Controller, R. Callender, Brantford, Can., 511,973. Filed Apl. 24, 1893.

Provides means for automatically controlling a circuit either as to the length of time it shall remain active or inactive or as to the length of time between beginning and completing the act of opening or closing the circuit.

Electrical Transmission of Power, Nikola Tesla, 511,915. Filed May 15, 1888.

A method of operating motors having independent energizing circuits consisting in passing an alternating current thorough one of the energizing circuits and inducing thereby a current in the other energizing circuit.

Regulator for Continuous Current Arc Light Circuits, D. Higham, Boston, Mass., 512,027. Filed May 14, 1892.

Employs means for producing in a branch circuit current waves differing in phase from the current waves in the main circuit and adapted to act upon the controlling device.

Transmission of Rapidly Alternating Electric Currents, W. H. Eckert, New York, 512,102. Filed Oct. 11, 1893.

The method consists in developing a series of alternating impulses and transmitting them over a conductor of bimetallic wire consisting of iron or steel combined with copper. (See THE ELECTRICAL ENGINEER, Jan. 10th).

Dynamos and Motors :—

Electric Motor, W. A. Crowdus, Chicago, Ill., 511,758. Filed Oct. 11, 1892.

A small easily constructed motor for use in connection with sewing machines, etc.

Electric Generator, N. Tesla, New York, 511,916. Filed Aug. 19, 1893.

Claim 1 follows :

The combination with the piston or equivalent element of an engine which is free to reciprocate under the action thereon of steam or a gas under pressure, of the moving conductor or element of an electric generater in direct mechanical connection therewith. (See THE ELECTRICAL ENGINEER, Jan. 10.)

Regulator for Dynamo Electric Machines, C. E. Scribner, Chicago, Ill, 512,227. Filed Dec. 29, 1887.

The method consists in changing coils of the field magnets from a shunt to a series relation with the working circuit to change the strength of the magnets.

Galvanic and Thermo-Electric Batteries :—

Cartridge Shell Battery, J. J. Pearson, Brooklyn, N. Y., 512,055. Filed Jan. 25, 1893.

A small sealed battery employing an ordinary cartridge shell for its outer casing.

Measurement :—

Ammeter and Voltmeter, J. Perry and C. E. Holland, London, Eng., 511,791. Filed April 6, 1893.

Has for its object to adapt the Ayrton & Perry magnifying spring ammeters and voltmeters to use upon a switch board in any position by giving them a vertical dial.

Electric Indicator, A. H. Hoyt, Manchester, N. H., 512,250. Filed March 15, 1893.

Has for its object to provide a device by which the movement of the needle can be checked and the reading made immediately after the current is applied.

Miscellaneous :—

Method of Removing Tin from Tin Plate Scrap, H. L. Hollis, Chicago, Ill., 511,774. Filed Jan. 13, 1892.

Consists in connecting the scrap with the positive pole of a source of electricity and removing the tin coating by electrolysis.

Electro Hydrocarbon Engine, L. C. Mann, Gladbrook, Iowa, 511,855. Filed Nov. 15, 1892.

Electric Clock, F. L. Gregory, Niagara Falls, N. Y., 511,946. Filed Apl. 19, 1892.

Electric Current Regulator, A. B. Jones, Cleveland, O., 512,115. Filed June 10, 1891.

A regulator for electrical dental tools.

Process of Purification and Decoloration of Saccharine Solutions, P. H. Vander Weyde and O. Lugo, New York, 512,133. Filed July 24, 1893.

Articles Coated With Metallic Alloys, S. O. Cowper-Coles, London, Eng., 512,160. Filed Nov. 25, 1892.

Relates to the electric deposition of certain specified alloys.

Process for Manufacturing Sugar, O. Lugo, New York, 512,200. Filed Nov. 10, 1893.

Electric Stop Motion for Warping Machines, Clayton Denn, J. Cocker and Chas. Denn, Philadelphia, Pa., 512,018. Filed Feb. 6, 1893.

Railways and Appliances :—

Trolley, W. F. Duncker, Steelton, Pa., 511,763. Filed Aug. 26, 1893.

Claim 2 follows :

A trolley having a pulley and provided at opposite sides of the same with separate outwardly tapering conical bodies provided with spiral grooves.

Trolley Mechanism for Electrically Propelled Vehicles, C. H. Veeder, Lynn, Mass., 511,824. Filed Nov. 23, 1892.

A construction of the trolley pole and connections especially adaped to electric mining locomotives.

Trolley Wire Support, C. T. Lee, Boston, Mass., 511.858. Filed Apl. 15, 1893.

Consists of an ear provided with metallic strips temporarily secured to the ear by solder and sufficiently long to be bent around the conductor while it is being permanently secured to the ear.

Electric Locomotive for Elevated Tracks, C. H. Roberts, Hartwell, O., 511,862. Filed Oct. 29. 1891.

An electric over-head railway adapted especially for logging purposes.

Trolley Catcher, G. E. Gay & J. H. Parsons, Augusta, Me., 511,941. Filed Feb. 28, 1893.

A spring attached to the trolley cord, normally held out of action but released by the tightening of the cord which occurs when the trolley leaves the wire, and actuating mechanism for winding up the cord and thus drawing down the trolley cord.

Electric Locomotive, E. M. Bentley, Boston, Mass., 511,988. Filed Oct. 24, 1891.

Relates especially to a flexible support for the motor upon the truck and means for transmitting power to the axle.

Overhead Trolley Wire Switch, G. W. Mac Kenzie, M. B. Sloan & T. C. Sloan, Beaver, Pa., 512,201. Filed Dec. 30, 1892.

Consists of a pivoted bridge piece operated by the trolley wheel of a passing car.

Switches and Cut-Outs :—

Electric Switch, J. L. Hinds, Syracuse, N. Y., 511,889. Filed May 16, 1892.

Relates to special features in the construction of jack knife switches.

Push Button, C. D. Hunking, New York, 511,953. Filed Jan. 6, 1893.

Claim :

A push button or circuit closer, comprising circuit terminals, a transparent opening, a pivoted index needle in or below the same, and an electro-magnet in the circuit of the terminals for operating the needle.

Telegraphs :—

Self Closing Telegraph Key, H. E. Moss, Kansas City, Mo., 511,787. Filed Aug. 21. 1893.

Telephones and Apparatus :—

Telephone Exchange System, R. Callender, Brantford, Can., 511,874. Filed May 12, 1893.

An automatic exchange apparatus and method of operation whereby any subscriber may obtain control of one section of the switching apparatus instantaneously, and to the exclusion of all other subscribers from the use of that particular section for a brief space of time sufficient to effect the desired connection, and then through the mechanism thus actuated to automatically disconnect the section of switching mechanism used and leave it for the use of any other subscriber, while he (the first named subscriber) continues his conversation unmolested with the subscriber called, and at the end of that conversation restores his line, and the line of the subscriber to whom he is talking, to normal condition.

Telephone Exchange System, R. Callender, Brantford, Can., 511,875. Filed Aug. 13, 1892.

Similar in its object to No 511,874.

Telephone Transmitter, S. C. Drew, Boston, Mass., 511.882. Filed Jan. 23, 1893.

Employs a diaphragm and an electrode placed in an electric circuit and a magnet arranged to be directly influenced by the vibrations of the diaphragm and by its changes in form to vary the pressure upon the electrode.

Registering Apparatus for Telephones, A. R. Duperu, San Francisco, Cal., 511,883. Filed Nov. 17, 1892.

Composite Telephonic and Multiple Telegraphic Transmission, F. A. Pickernell, Newark, N. J., 512,214. Filed Aug. 25, 1893.

The main telegraphic line serves as one side of a two wire telephone circuit.

THE NEW YORK POLICE TELEGRAPH SYSTEM.

A SUMMARY of the work performed in the New York Bureau of Police Telegraph for 1893, as given out by the Superintendent, Mr. Brennan, shows that the total number of miscellaneous messages transmitted over the police telegraph and telephone lines for police and other departments were 113,954; general alarm messages, comprising general orders of the Board of Police, Superintendent of Police, inspectors, etc., 224,364; dead animals reported over wires, 35,000.

During the year eighty miles of electric wires for the police telegraph and telephone systems were put under ground, and fifteen miles of police wires were transferred from pole lines, so as to allow the Board of Electrical Control to remove poles.

It is intended to equip all the other police stations, police courts, and public hospitals with telephones connecting directly with police headquarters, with underground wires.

HONORS FOR MR. PREECE.

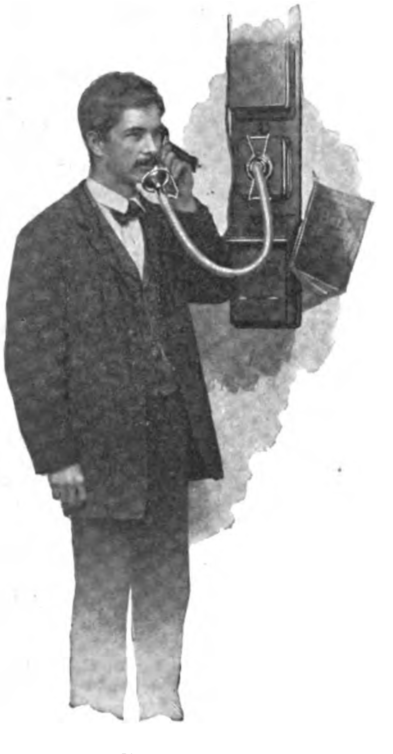
The hosts of friends of Mr. W. H. Preece, F. R. S., in this country will be delighted to learn that the Queen has included his name in the list of New Year's honors by making him a Companion of the Bath, thus recognizing his merit and honoring the profession of which Mr. Preece is so useful and distinguished a member.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE WEBER TELEPHONE ATTACHMENT.

A DEVICE for facilitating the use of wall telephones by persons of any height; obviating the necessity of stooping or standing on tip toes, as the case may be, has been introduced by Messrs. Weber & Brother, of 2,209 and 2,211 North Front street, Philadelphia, and is clearly shown in the accompanying illustration. It consists merely of a flexible tube one end of which is attached to the transmitter by a spring clip. At the other end is the ear-piece and another clip which holds the receiver at the proper distance from the mouth when in use. One may thus stand in a natural attitude, or even sit, and at the same time have an uninterrupted view of his surroundings. The attachment is said to have a very soothing influence upon the user of telephones and to enable him to roar you as softly as any sucking dove.



THE WEBER TELEPHONE ATTACHMENT.

THE QUEEN ELECTRODYNAMOMETERS.

QUEEN & Co., INC., Philadelphia, make a special form of electrodynamometer which they have supplied largely to central stations and manufacturing concerns, for use as a standard ammeter in measuring both direct and alternating currents. The fact that instruments built upon this plan are capable of very exact calibration which does not change, renders them reliable and efficient where other forms cannot be employed.

This is particularly the case in alternating work. The series of ammeters which Queen & Co. manufacture cover a range of from two tenths amp. to five hundred amperes.

INCREASED EDISON EARNINGS IN NEW YORK CITY.

THE EDISON ELECTRIC ILLUMINATING COMPANY reports for the calendar year 1893:

Gross earnings	$1,193,338	Inc.	$250,763
Operating expenses	527,311	"	141,817
Net earnings	$666,027	Inc.	$108,946
Other income	28,221	"	7,775
Total income	$694,248	Inc.	$116,722
Legal expenses and taxes	112,570	"	10,181
Net earnings	$581,678	Inc.	$106,541

ACTIVITY OF THE LA ROCHE ELECTRIC WORKS.

THE La Roche Electrical Works, Philadelphia, have installed the following plants within the last month in their own vicinity: Duncan, Hood & Co,, 400 lights; M. C. Curdy Bros., 500; R. H. Foster Works, 1,500; Hotel Emery, 200; T. Devlin & Co., 500; Allegheny Woolen Mills, 400. They have also sold plants for 1000 lights to the Westboro, Mass., Electric Light & Power Co.; Biloxi. Miss., Light and Power Co., 1000; Quincy, Mass. Electric Light and Power Co., 1300; Buckingham, N. C., 500. This is a fine list for dull times. The La Roche Works have also sold motors aggregating 150 h. p., with machinery, etc., of proportionate amount. The company are working night and day as they have now on hand to fill at once orders for nearly 8,000 lights of dynamo capacity and 75 h. p. of motors. Among the newer work just contracted for may be mentioned the Wernersville Insane Asylum plant of 2,000 lights.

The company held its annual meeting last week, when the statements presented gave evidence that for the La Roche Works at least the year had been a very successful one and that the outlook for 1894 was very bright. The company have just taken 15 additional men on, in order to keep from falling behind with the work now in hand.

ACTIVITY OF THE ELECTRIC APPLIANCE CO.

THE success of the new "Mogul" lamp is said to be nothing short of phenomenal. The orders that the factory are receiving are already taxing their capacity. It begins to look as though the "Mogul" was the coming lamp for large interior lighting, such as halls, theatres, churches, etc. In fact a number of contracts for this kind of work have already been made. The Electric Appliance Company, of Chicago, as western agents for the New York & Ohio Co., are carrying a stock of the lamps in Chicago and making large sales.

The Electric Appliance Company report that the interest manifested in the new Washington arc lamp for alternating and direct current constant potential circuits is becoming very general and inquiries and orders are coming in from all parts of the country.

METROPOLITAN ELECTRIC CO.

The following notice to the trade has just been issued by the Metropolitan Electric Co. of 186–188 Fifth Avenue, Chicago :—

> We have been transacting our business heretofore under disadvantages (on account of the necessary separation of our sales and warerooms from our offices) owing to leases existing when this company bought out the Enterprise Electric Company, which are satisfied.
>
> We have now leased a new store and warerooms that will accommodate these interests and give us more direct supervision over our affairs, with the additional advantage of increased space which will permit us to carry larger stocks of staple articles; and exhibit our specialties, insuring our customers more prompt attention than we have been able thus far to give.
>
> Please make a note of our new address, which will be permanent, 186–188 Fifth avenue, Chicago.
>
> We shall be glad to have you call upon us in an official capacity, or otherwise.
>
> Yours very truly,
> Metropolitan Electric Company,
> Wm. H. McKinlock,
> President.

THE HOWARD INCANDESCENT ARC LAMP IN HARTFORD.

WE have received a batch of testimonials from the Connecticut Royal Arc Co., as to the operation of the Howard incandescent arc lamps placed by them in the city of Hartford, in stores and offices. All the users speak of them in the highest terms, as might have been expected, dwelling in several cases also on the freedom from danger of fire.

THE BROWN PUG DOG.

ONE of the most original designs in calendars is that issued for 1894 by the Brown Electric Co., Summer and Federal streets, Boston, Mass. It represents a pug dog, who will at command sit up on a desk and present to the person interested the business card of the Brown Company, which is held in the teeth of the dog. The calendar for the year is in plain sight and the whole get up of the device is certainly novel.

MR. JOSÉ ELIGIO MOSQUERA, of Havana, Cuba, informs us that he has removed his offices and stores to No. 88 Calle del Obispo that city, where he will continue to keep on hand a large variety of electrical house, telephone, telegraph and similar supplies. He will also devote special attention to electric light and railway apparatus, and all details relating to electrical installations generally. Mr. Mosquera invites correspondence on all matters pertaining to the above.

THE WALKER MFG. CO.'S ELECTRICAL DEPARTMENT.

Since the announcement that the Walker Manufacturing Company had decided to add an electrical department to its immense plant, for the manufacture of street railroad dynamos, motors and other electrical transmission machinery, work has progressed rapidly. The first machines to be placed on the market are now nearing completion, and within a short time the company will be in active business in this line of work.

It was predicted at the time of the announcement that the Walker people would prove an unusually strong factor in the electrical field, and this prophecy is borne out by the fact that business has already been offered the company, both from Eastern and Western roads. Judging from recent reports, there appears to be no doubt in the minds of those in any way interested, of the immediate and unqualified success of the new machines. The closest attention has been paid to mechanical detail. The improvements suggested and already carried out, are considered by experts to be a distinct advance.

The "Wheel-type" idea has been followed in the designs for generators, and this plan will prevail throughout. So far it has been impossible to obtain details of construction, as the company's officers are not yet ready to give out specific information.

WALLACE ELECTRIC COMPANY.

The Wallace Electric Co. of 104 Michigan avenue, Chicago, has issued the following important announcement:—

> We take pleasure in informing our friends and the trade that the Wallace Electric Company has been organized for the purpose of conducting a business in electrical goods as manufacturers and manufacturers' agents.
>
> Our line embraces alternating current generators, motors, meters, transformers, etc.
>
> Wires and cables for all electrical purposes.
>
> Incandescent and arc lamps, measuring and indicating instruments, switches, etc.
>
> Also a full line of electrical street railway appliances and supplies and a few carefully selected specialties.
>
> The officers and management of the Company are well known to the trade. Our General Manager, Mr. J. B. Wallace, has been actively identified with electrical industries from the earliest experimental stages of electric lighting in this country. Mr. Wm. S. Hine, our President, has had a large experience in this business through his connection with the U. S. Electric Lighting Co. and the Westinghouse Electric and Mfg. Co. as General District Agent. Mr. Max A. Berg, Secretary of the Company, is well known as the former Manager of the Street Railway Dept. of the Ansonia Electric Co., and Mr. M. M. Wood, whose special devices are rapidly becoming the standard for Street Railway Construction, will be our Electrical Engineer in this department.
>
> We are not Electrical Supply Dealers, but as Manufacturers and Manufacturers' Agents, are in a position to sell directly to large consumers and the trade at manufacturers' prices and without an intervening profit.
>
> Catalogues, price lists, etc., are in press and will be mailed on application.
>
> We are thoroughly equipped to promptly and satisfactorily handle your business and solicit your orders.

THE COLUMBIA INCANDESCENT LAMP.

President J. H. Rhotehamel, of the Columbia Incandescent Lamp Co., St. Louis, reports that the recent reduction in price of their lamps has overflowed their factory with orders. They have been compelled to operate overtime and are now considerably behind. He says: "There is no question that the users of incandescent lamps in the United States are beginning to appreciate the fight we have made for an open market; and the most substantial evidence we have of this is our orders from all sections o country."

BERLIN IRON BRIDGE CO.

The new works of the Stanley Electric Mfg. Co., at Pittsfield, Mass., will be entirely of iron, designed and built by the Berlin Iron Bridge Co., of East Berlin, Conn.

The Berlin Iron Bridge Co., are putting the roof on a building for the United Sates Government, at Fort Wadsworth, N. Y. The building is 41 feet wide and 231 feet long, the roof being made entirely of iron,—iron trusses covered with corrugated iron.

HOW THE STUDENTS LIKE IT.

A student at one of the leading technological institutes writes: "I take pleasure in enclosing my subscription for the coming year to The Electrical Engineer. as I have found it the finest in the land."

NEW ENGLAND NOTES.

Our New England Office extends its thanks for beautiful calendars to the W. S. Hill Electric Company, the Hawks Electric Company, the Pettingell Andrews Company, the Brown Electric Company, A. & J. M. Anderson, and many others who were kind enough to send them. Yet there is room.

The Page Belting Co. of Concord, N. H., have made a decided hit by publishing in diploma form their award at the World's Fair, accompanied by a facsimile of the St. Gaudens medal which is now creating such a sensation in sewing circles and the U. S. Senate because of the nudity of a male figure on one side of it.

Messrs. A. and J. M. Anderson, of Boston, in sending out their New Year's cards, which consists of a four-page circular showing cuts of their various railway appliances, together with a circular letter or two and a memorandum of an official test of their "Brooklyn Strain Insulator," have inclosed a very handsome calendar for 1894. The engraving is a work of art, making a picture pleasing to the eye, while the calendar proper is most satisfactory and useful.

NEW YORK NOTES.

Mr. A. B. Lawrence, 225 Pearl street, sends us a very showy and pretty calendar of the celebrated Shultz belting. Engineers and superintendents can get copies of it for the asking and a 2-cent postage stamp.

Messrs. Bogle & Scott, importers and grocers, of 87 and 89 Park Place, have installed in their new building at 120 Hudson street, New York, a 60-light Belknap dynamo which will be run by a well-known make of gas engine.

Mr. Wm. H. McKinlock, president of the Metropolitan Electric Company, Chicago, has been called to New York to close a contract for a full line of specialities, which the company are now in a position to handle advantageously in their commodious store and warerooms, 186 and 188 Fifth ave.

The Cowles Electric Smelting & Aluminum Co. of Lockport, N. Y. authorize and request us to contradict the report that they are consolidating with the Pittsburgh Reduction Co. or have any intention of so doing. They do not expect to remove to Niagara Falls and their Lockport works are in active operation as usual turning out aluminum and its alloys.

The Reward for Inventors.—Mr. Edward P. Thompson, 3 to 7 Beekman St., New York, reports patent searches in electric railway systems, which would naturally suggest that inventors are competing for the $50,000 prize decreed by the Metropolitan Traction Co. He has done so much in this direction just lately that he feels competent to furnish inventors with the whole history of electric railways of all types.

The Abendroth & Root Mfg. Co., 28 Cliff street, are quite pleased at having secured the contract for 4,000 h. p. of boilers from the Cincinnati Street Railway Co. This will be the complete boiler equipment in two power houses, and part of the equipment in a third. The company also report having secured the services of Mr. P. McLaren, one of the oldest and most successful representative salesmen in the boiler trade. Their outlook was never better than to day.

The Consolidated Car Heating Co. of Albany has begun suit in the United States Circuit Court against the Chicago & West Michigan Railway for infringement of the Sewall coupler patents. The alleged infringement consists of using an imitation of the Sewall Steam Coupler recently put upon the market. This railway is the first to continue the use of the imitation coupler after notification, and the Consolidated Car-Heating Co. at once determined to take action to protect the patents issued to Messrs. D. D. and J. H. Sewall.

PHILADELPHIA NOTES.

The Altoona Manufacturing Company, of Altoona, Pa., builders of the M. A. Green engines, have recently appointed T. T. Burchfield, No. 55 North 7th St., Philadelphia, Pa., as their representative in that city.

Spaulding & Metcalf have removed to their now store 532 Arch street, where they will carry a more complete line of mill and electrical supplies. Their business is growing rapidly and 1894 promises to be a very prosperous year for them.

Mr. Chas. Blizard, general sales agent, Electric Storage Battery Co., of Philadelphia, is at present in Chicago, and will probably remain there for some weeks looking up prospective business. He will possibly arrange for permanent operations in the West. Pending these arrangements he has taken temporary offices in Chicago, 302 Owings Building.

The Main Belting Co., of Philadelphia, have issued a gilt-edged pocket memorandum book, with celluloid covers, bound with leather. The name and address of the Company, and a "Group of Leviathans" are in possession of the front cover, while the back is occupied by a calendar for the year. There are contained in the book a price list of belts, some general instructions as to their handling, and a few remarks calculated to instruct the user as to how to get the most work from his belting.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XVII. JANUARY 31, 1894. No. 300.

BI-METALLIC TELEPHONIC CONDUCTORS AND THEIR RELATION TO RESONANCE ON LONG DISTANCE CIRCUITS.

BY F. W. DUNBAR.

IN an interesting article appearing in THE ELECTRICAL ENGINEER of Jan. 10,[1] the possible advantages of a composite or bimetallic conductor for telephonic purposes are brought forward. It has been the universal experience that a plain iron or steel conductor is unsuited for telephonic transmission over long distances. Not only is the volume of the transmitted sound less over such circuits than over the standard copper circuits, even if the weight per mile be increased sufficiently to secure an equal conductivity, but also the quality of the transmission is inferior. Were it not for this second reason it would at first thought appear possible to advantageously use simple iron or steel circuits in place of copper for distances exceeding several hundred miles. For, as is commonly recognized, on copper circuits of such a length the value of the current at the receiving end may be increased by the addition of the proper amount of distributed self-induction, or retardation If then an iron wire were substituted of equal conductivity to the copper, and consequently weighing about six times as much, it would seem possible to increase the value of the current at the receiving end, if the increased self induction of the iron were of the proper amount.

The value of the self-induction necessary to secure a maximum current at the distant end is given by $L = \frac{C R^2 l^2}{16}$ in henrys per mile, where

C = capacity in farads to ground per mile,
R = resistance in ohms per mile,
l = length of metallic circuit in miles.

This is an approximate equation true when the rate of alternation is within the range of the telephonic vibrations and upon lines exceeding several hundred miles in length; that is upon those lines where resonance is possible. This yields for a metallic circuit of 2,000 miles (or a distance of 1,000 miles, corresponding closely to the Chicago line) with No. 8 B. W. G. copper wires 30 feet above the ground $\frac{.017 \times 4.84 \times 4 \times 10^6}{10^6 \times 16} = .0204$ henry per mile. In practice these wires have but about .00165 henry per mile, or less than a tenth of the value necessary to secure the maximum possible current.

The value of the inductance of a No. 000 B. W. G. iron wire in place of the No. 8 copper would be, assuming a value of 150 for the inductivity of the iron, $75 + 2 \log_e \frac{d}{r} = 83$ cm. per cm. or .0123 henry per mile. This is the value of μ given by Mr. Kennelly and substantiated by the experiments of Lord Rayleigh. Thus the circuit if built of No. 000 iron would come much nearer to yielding the amount of inductance necessary to secure a maximum current at the distant end. As a matter of fact any nearer approach would be attended with but a very slight increase in the current.

The increased size of the iron wire would have increased the capacity over the copper wire in the ratio of

$$\frac{\log \frac{4h}{d}}{\log \frac{4h}{d} - \log \frac{.425}{.165}} = 1.117;$$

where h is the height of the wire in cms. above ground and d is the diameter of the copper wire in cms. The No. 8 copper wire has a capacity of .017 microfarad per mile, hence the No. 000 iron will have a capacity of .019 microfarad per mile.

The value of the current at 160 cycles per second at the distant end of the circuit when the sine of the phase is unity is for No. 8 copper wire

$$\frac{2E\sqrt{\frac{17}{10^6}}\; e^{\sqrt{\frac{17}{2}}\sqrt{(4.84+2.56)^{\frac{1}{2}}-1.6}}}{\sqrt[4]{4.84+2.56}\; e^{2\sqrt{\frac{17}{2}}\sqrt{(4.84+2.56)^{\frac{1}{2}}-1.6}}-1} = E \times .000244$$

ampere, and for the iron wire

$$\frac{2E\sqrt{\frac{19}{10^6}}\; e^{\sqrt{\frac{19}{2}}\sqrt{(4.+151.29)^{\frac{1}{2}}-12.8}}}{\sqrt[4]{4+151.29}\; e^{2\sqrt{\frac{19}{2}}\sqrt{(4.+151.29)^{\frac{1}{2}}-12.8}}-1} = E \times .000798$$

ampere.

Thus, were simple iron wires weighing six times as much as the copper, used in place of the copper, the resulting current would apparently be increased over 200 per cent.; a result that is not in accordance with all inferences to be drawn from actual observations.

But as Maxwell and many subsequent writers have shown, the true resistance which a conductor offers to an alternating current is greater than that resistance which it offers to a uniform current. This statement is entirely distinct from the increase in apparent resistance, due to the self induction of the circuit itself, and commonly termed the impedance, $\sqrt{R^2 + L^2 \omega^2}$. The increase spoken of is an actual increase in the resistance of the conductor itself and causes a greater energy dissipation in the form of heat.

It is caused by the unequal densities which the current assumes throughout the cross-section of the conductor and increases in amount as the density becomes less and less uniform. As an alternating current can only establish itself by continually overcoming and reversing its own field of self induction, and as its own self induction is a function of the distribution of the current throughout the cross-section of the conductor, it will naturally assume that distribution which yields the lowest self-induction, or which offers the minimum opposition to its change. The equation of the self-induction per unit of length is for a uniform distribution $L = \frac{\mu}{2} + 2 \log_e \frac{d}{r}$, where μ represents the inductivity of the conductor and air is assumed as the dielectric. The first term follows naturally from the consideration that the lines of force contained by the conductor itself cut on the average but one half the total current when the distribution is uniform, as assumed. If however we assume the distribution to be an entirely surface distribution then the first term of the self-induction $\left(\frac{\mu}{2}\right)$ entirely disappears.

---

[1] Bi-Metallic Wires for Telephone Conductors.

Thus, an alternating current will seek a distribution which decreases in density toward the core of the conductor and hence the true resistance of that conductor will be increased and its true self induction decreased.

The magnitude of these changes depends upon the possible decrement of self induction secured by means of this change in the distribution and hence varies with the permeability of the conductor. As μ is approximately unity for copper, $\frac{\mu}{2}$ will form but a small portion of the total self-induction of a copper circuit and consequently the increase in resistance and decrease in self induction will be negligible until excessive rates of alternations and diameters of conductor are reached.

But as the term $\frac{\mu}{2}$ forms the principle part of the self-induction of iron wire circuits the true resistance and self-induction will be considerably altered for telephonic rates.

The true resistance per unit length (cm.) is given by the series developed by Lord Rayleigh.

$$R_1 = R\left[1 + \frac{1}{12}\left(\frac{\omega^2\ \mu^2}{R^2}\right) - \frac{1}{180}\left(\frac{\omega^4\ \mu^4}{R^4}\right) + \ .\ .\ \right]$$

For an iron wire as large as No. 000 B. W. G. the term $\left(\frac{\omega\,\mu}{R}\right)$, at even 160 alternations per second, too greatly exceeds unity to be readily developed. We can however approximate its value from the values of those sizes which the series will readily develop.

Ohms per mile.	Percentage increase in resistance @ 160 ~	
	Calculated.	Exterpolated.
64.	1.18	
32.	4.58	
16.	16.23	
8.	approx. 45.	
4.		90
No. 000 2.		160

Thus the iron wire assumed to have a resistance of two ohms per mile has really about 5.2 ohms per mile at 160 alterations per second. Also, as seen, the true resistance is different for every rate of alternation, increasing at low rates with the square of the rate and at all time increasing rapidly with the rate. At 320 alternations the true resistance would be approximately 7.5 ohms.

Thus the apparent increase in current at the distant end by the substitution of iron wires in place of copper disappears, for the true resistance is greater and the true self-induction less, than those values used in the calculation, and both of these factors tend to rapidly decrease the value of the receiving current.

But the mere fact of the increase in resistance with an increase in the rate of alternation would be sufficient in itself to debar the use of simple iron circuits for telephonic transmission; for as the higher overtones will be present with diminishing intensity the articulation must necessarily be poor and will grow worse as the line is increased in length. But the bi-metallic conductor which Mr. Eckert proposes has a heavy copper deposit upon an iron core. Therefore its true resistance would be but little altered by an increase in the rate of alternation, and we should expect it to give practically as good articulation as a pure copper conductor. Also as the copper sheath forms the principal conductor for the telephonic current we should expect a volume of transmission equal to that secured by a pure copper conductor of the same conductivity, or to that secured if he should neglect to put in the iron core.

Mr. Eckert's point that a single bi-metallic conductor has an efficiency in volume and articulation equal to that secured by two all-copper metallic conductors of equal conductivity per unit length and used as a closed metallic circuit, is undoubtedly true. It is equally true with reference to a single all-copper conductor.

The addition of the "return" wire in the metallic circuit was not made either to increase the volume nor improve the quality of the transmission; both remain practically unchanged; but the earth currents which are always present to a greater or less extent, and which increase in intensity with an increase in distance, together with the inability to prevent cross-talk between parallel grounded circuits were the causes which necessitated the addition of the "return" wire.

Had Mr. Eckert reversed the position of his metals and used a conductor with a copper core and an iron sheath he would have placed his iron where it would be useful; for then he would have secured a copper conductor possessing all the advantages of an increased retardation and none of the disadvantages of a pure iron conductor, *if the ratio between the iron and copper is of the proper value.*

The equation for the self-induction of such a circuit is

$$L = \tfrac{1}{2} + 2\log_e\frac{d}{r} + 2\,\mu\log_e\frac{r_1}{r}$$

where r_1 and r are the radii of the sheath and core respectively and d is the distance between the conductors. $\mu = 150$ as before.

The problem is to put on an iron sheath just sufficient to make $L = 20.4$ henrys per mile. $2\log_e\frac{d}{r} = 10.00$; hence $\log_e\frac{r_1}{r} = \frac{117}{300} = .39$ or $\frac{r_1}{r} = 1.48$, hence $r_1 = .244$.

Therefore, if an iron sheath .079 thick were added to the copper conductors under discussion the inductance would be just sufficiently increased to bring the circuit into resonance and yield the maximum possible current at the distant end.

The ratio between the currents at the transmitting and receiving end of the line is $\frac{2\,e^{\frac{pl}{2}}}{e^{pl}+1}$.

When the capacity and self-induction are present in the proper proportions to bring the line in resonance the exponent $\frac{pl}{2}$ has a value unity, and the ratio becomes $\frac{2\,e}{e^2+1} = .64$.

Hence, when a circuit containing distributed capacity and self-induction is brought into resonance and the current at the distant end thus rendered a maximum, there is still a considerable loss upon the line.

This is, of course, due to the short-circuiting effect of the capacity of the line and was admirably pointed out by Dr. Pupin in his lecture before the New York Electrical Society January 16, 1893.

This loss may be still farther reduced by increasing again the self-induction of the line and when the self-induction has an infinite value the loss will be zero—so also will the current be at all points of the circuit.

This is the mistake that many writers too well known to require mentioning have made. They have aimed at securing a minimum loss upon the line, which is entirely different from bringing the line into resonance and thus rendering a maximum current at the distant end.

The interesting point is that the percentage loss upon the line (36 per cent.) is independent of the length of the circuit. This however does not mean that the *current* at the distant end is independent of the length of circuit.

The bringing of a line into resonance increases its "resiliency"—stiffens it up, as it were. It can no longer receive the same amount of current at the transmitting end for a given impressed E. M. F. but the decreased amount which it does receive, it transmits with perfect resonance and with a uniform loss of 36 per cent.

The point has already been made in my article appearing in THE ELECTRICAL ENGINEER of January 10, 1894, page 29, equation (11), that if a circuit containing distributed capacity and self induction be brought into resonance for any wave length within the range of telephonic vibrations, it will be perfectly resonant to any other. This is distinctly different from the laws of localized capacity and self induction and is the salvation of long distance telephony. For if pains be taken to bring the circuit into resonance, no matter what its length may be, the articulation will suffer no loss during transmission.

One other point in the resonance of circuits is important and instructive. The value of the current at the distant end of the circuit secured when the line is in resonance is always greater than that current which could be secured by an equal impressed E. M. F. were the line devoid of capacity and self-induction, and thus followed Ohm's law with *no* loss upon the line.

In conclusion then we would seem justified, in saying that were an iron sleeve .08 inch thick (or even .04 inch would yield practically identical results) added to the No. 8 B. W. G. copper wire between New York and Chicago, the circuit would be brought into resonance and the current at the receiving end would be but 36 per cent. weaker than at the transmitting end. This would bring Chicago practically 700 miles nearer New York, and would allow commercial conversation to be carried on by means of anything from the original Reis transmitter to the latest form of long distance instruments.

A more practical consideration however is, that had about one-third the amount of copper been put in the circuits between New York and Chicago, the value of a second third been placed in an iron sheath and the remaining third been allowed to repose in the pockets of the investing public, our business men of to-day who now have to surrender nine whole dollars for every five minutes conversation, would be getting more for their money and a more satisfactory article at that.

INFLUENCE OF COLD ON MAGNETS AND ELECTRIC DISCHARGE IN VACUO.

Prof. Dewar is making steady progress in his wonderful discoveries as to the effects of low temperature. He gave the results of his more recent experiments in a lecture before the Royal Institution, London. The table was covered with many flasks of liquefied air enveloped in carbonic acid snow. He said he had proved that at absolute zero all metals have the same degree of conductivity to electricity, however much they may differ at higher temperatures. Prof. Gladstone's theory of refractive indices of gases had been perfectly confirmed. He found that a low temperature greatly increased the strength of metals. Iron at — 180° centigrade had twice the cohesive power it possesses at an ordinary temperature.

A fully saturated magnet was found to have its power greatly increased by a reduction to — 180° centigrade. Intense cold has a strange effect on color. Professor Dewar sponged a scarlet card painted with iodine with liquefied air, and the brilliant scarlet changed to orange, but recovered its original hue immediately after it became warm again. Many brilliant experiments were made by sending electric discharges through exhausted glass globes. All the well-known phenomena of phosphorescence ceased as soon as intense cold was applied. The electricity tried to pass by any route rather than through the globe. What did this mean? asked Professor Dewar. Obviously that something was now frozen out which had before enabled electricity to pass across the vacuous space.

THE COPPER-ZINC ACCUMULATOR.—II.

BY

D Paul Schoop

The explanation of what constitutes the chemical part of the Lalande cell, given in Part I, will be often referred to later on, since about the same reactions occur during the discharge of the Desmazures and of the Phillips-Entz secondary battery. Let us confess at once, that most likely the chemical or electro-chemical processes during the discharge of Lalande's battery are far from being as here set forth. The *tendencies* of each reaction, pointed out separately above, may be working all at the same time, each tendency contributing a certain percentage to the total amount of molecular strain which brings forth the final result.

Lalande has no doubt given a good deal of consideration to the question of electrically regenerating his discharged battery, but has never claimed to have performed it. He proposed, to "revive" or regenerate one part of the battery, the porous, metallic copper, by exposing it to the air, whereby oxygen is absorbed by the copper. It depends upon how finely divided or porous the spongy copper is, at what temperature it is exposed to the air, and whether the caustic potash remaining in the spongy mass has been more or less carefully washed out—whether more or less oxygen is taken up by the copper; or in other words, how far the regeneration is carried on. By washing the spongy copper of the discharged Lalande cell with distilled water, drying the wet material to drive out all the water, and finally heating it to about 300 degrees C., the regeneration is perfected and by placing this product again in the battery, the same amount of current may be again delivered from it, provided there is still zinc and caustic-potash in abundance.

Instead of regenerating the oxidized copper in this way, it can be done electrically. But it seems doubtful at first sight, whether this will be as cheap a way as the one just described. Besides, the electric method is not at all so simple. If a current is passed through the discharged Lalande cell in opposite direction to the discharge current, it will be found that the porous copper takes up oxygen and is changed into suboxide of copper, of a reddish or yellowish color, according to the nature of the reaction. But as soon as there is a trace of the higher oxidized black oxide of copper formed, the liquid near the copper side will acquire a pure blue color and, on closer investigation, will be found to contain copper.

The electrolytic liquid therefore *dissolves* part of the substance, formed by regenerating the copper anode. On the zinc plate, a very spongy, grey deposit will be seen, mainly at the line where the zinc plate cuts the surface of the liquid, or, if the plate be entirely submerged in the electrolyte, at its edges. This spongy substance is by no means pure zinc, but it contains a suboxide of zinc, mixed with more or less metallic zinc or, perhaps, also a compound of zinc and hydrogen. Therefore the regeneration of the zinc is not carried on by the electric current, in a regular and smooth way; it depends on the density of the current, the temperature of the cell, the composition of the electrolyte, and on a good many other points besides, how the deposit at the zinc plate is formed. Further on these points will be examined more closely; it may be mentioned here briefly, that as soon as a trace of the blue copper containing liquid reaches the zinc plate, a black deposit of finely divided copper is immediately observed on the zinc. At this stage local action is set up between the trace of copper and the zinc plate, causing the zinc to oxidize and dissolve in the alkaline liquid, while gaseous hydrogen escapes freely from the deposited copper.[1]

The Desmazures Battery. With a view to facilitating the electrical regeneration of the Lalande battery, Mr. Desmazures has given it an entirely different construction and has been forced to alter every single part of it correspondingly. The anode or the copper part is made by compressing finely divided copper—as obtained for instance by mixing precipitated oxide of copper with zinc powder and pouring this mixture into a solution of caustic soda, or as obtained by certain galvanic reactions—on a network of copper-wire. The pressure is about 1,000 atmospheres.

In this way, a plate of porous copper is obtained, about 3 mm. thick, and of sufficient mechanical strength to stand all the handling and shocks of practical use. The specific gravity of this copper plate, although it is pretty firm and hard, does not exceed 4.1 (about one-half of the specific gravity of the solid copper) and absorbs with great facility the bodies deposited by the galvanic reactions on its surface. The plate is surrounded by a frame and provided with a proper connection and then put in an envelope of parchment paper. A grid of insulating material, such as whiting or similar substance, insoluble in the alkaline liquid, is put on both sides of the plate and again an envelope of parchment paper is applied around the whole structure. In this way, the total thickness of the anode is about 7 millimetres.

The cathode, or that electrode at which the zinc is deposited, consists of three pieces of steel wire network, held together by an outer frame of sheet steel and a connection piece on top of the plate, which is rivetted to the steel network. Plugs of insulating material are attached to the plate, in order to keep it at uniform distance from the anode. Instead of insulating plugs, a grid of ebonite may be laid on each side of the cathode, so that the thickness of this part amounts to about 8 or 9 millimetres.

The box is made of sheet steel of 1 mm. thickness. The copper plate and the steel wire plates are placed alternately in the box, and the plates pressed tightly together. The connections are made by screwing all the copper connectors together and the same is done with all the steel connectors. The box is provided with an air-tight cover of sheet steel, through which the two poles of the cell enter. A little valve for the outlet of gases is also fixed on the cover.

The electrolyte consists of a concentrated solution of caustic-potash with a certain percentage of zinc dissolved in it and containing also some mercury. Its specific gravity is about 1.6; the liquid is colorless and without any odor. It is covered with paraffine oil, to prevent the absorption of carbonic acid from the air. The addition of mercury to the liquid greatly facilitates the proper deposition of zinc and suppresses also part of the local action between the deposited zinc and the liquid.

It is claimed by the inventor of this battery that its efficiency is even superior to that of any type of the lead accumulator. No current is lost during the charging of the battery, since no gas is developed even by overcharging. The internal resistance of the cell is given as 0.35 ohm per square-decimetre surface of plates (average). The efficiency in watt hours is given as 80 per cent. under normal conditions. The reliability, durability and convenience in handling this battery are stated to be superior to that of a lead cell, while the output of electric energy per unit of weight is claimed to be at least 1½ times as great as that of the best and lightest lead cell.

It is important to keep this copper-zinc accumulator free from contamination with ammonia, nitric acid, chlorine, or any like substances, liable to attack the copper or steel in the cell.

THE ELECTRO-MAGNET; or JOSEPH HENRY'S PLACE IN THE HISTORY OF THE ELECTRO-MAGNETIC TELEGRAPH.—IV.

BY

Mary A. Henry

Still brooding over the theory of Ampere, Henry was not content. The current was still led, although in a less degree, in an oblique direction, and not at right angles to the length of the iron bar. Sitting one evening at home in his study, lost in a deep revery, although a friend was with him, the idea came to him that he could obtain the condition the theory required by winding the wire backward and forward in several layers around the iron core.

> **"The successive spirals of wire, coiling first in one direction then in the other, would tend to produce a resultant action of the current at right angles to the core, and that furthermore in the great number of revolutions thus obtained the current would act on a greater number of molecules of the bar and so excite greater magnetism."**

He sprang to his feet, and striking his hand upon the table near him exclaimed: "To-morrow I will make an experiment which in its result will astonish the world." "When the conception," he said, "came into my brain, I was so pleased with it I could not help rising to my feet and giving it my hearty approbation!" (If this seems at variance with Henry's well-known and great modesty it must be remembered that it was an involuntary expression of delight, uttered only in the presence of a very intimate friend. Even modesty could not blind his eyes to the value of his researches in their bearing on the telegraph, which at this time, as later, he fully recognized). He made the experiment the next day, and to his delight and encouragement success again rewarded him.

He tested his theory on the magnet we have just described as lifting fourteen pounds. Over the wire, which was already closely wound on the iron core, he wound another insulated wire, in such a way as to give the effect of a long continuous wire wound upon itself. He says:

> **"A second wire of the same length as the first was wound over it, and the ends soldered to the zinc and copper in such a manner that the galvanic current might circulate in the same direction, or, in other words, that the two wires might act as one; the effect by this addition was doubled, as the horse-shoe, with the same plates before used, now supported 28 lbs. With a pair of plates, 4 inches by 6 inches, it lifted 89 lbs., or more than *fifty times its own weight*."**

Where was Sturgeon's magnet now, lifting only its nine pounds with its battery of one hundred and thirty plates, in comparison with this magnet of Henry's sustaining fifty times its own weight under the influence of only a single pair of plates? Fig. 1.

"The same principle," Henry says "was extended by employing a still longer insulated wire, and winding several strata of this over the first, care being taken to insure the insulation between each stratum, by a covering of silk ribbon. By this arrangement the rod was surrounded by a compound helix, formed of a long wire of many coils, instead of a single helix of a few coils."

> **"In the arrangements of Arago and Sturgeon the several turns of wire were not precisely at right angles to the axis of the rod as they should be to produce the effect required by the theory, but slightly oblique, and therefore each tended to develop a separate magnetism not coincident with the axis of the bar. But in winding the wire upon and over itself the obliquity of the several turns**

---

[1] **Professor H. S. Carhart, in his book, "Primary Batteries," gives a splendid description with illustrations of three different types of the Lalande battery, and most careful and scientific tests of the Edison-Lalande type. The perusal of Professor Carhart's book is highly recommended to all interested in this subject.**

compensated each other, and the resultant action was at right angles to the bar. The arrangement then introduced by myself was superior to those of Arago and Sturgeon, first, in the greater multiplicity of turns of wire, and, second, in the better application of these turns to the development of magnetism. The power of the instrument with the same amount of galvanic force was by this arrangement several times increased."

Was there a limit to the process; could the magnet already so strong continue to increase in power as more and more wire was wound in this way upon it? Henry found, after a certain length of wire had been coiled upon the iron, that the power diminished with the further increase of the number of turns. This was due "to the increased resistance which the longer wire offered to the conduction of the electricity." Had a limit indeed come to the power of the hitherto willing magnet to respond to the ever increasing demands of the young philosopher? No; Henry, undaunted, conceived a method of producing still greater power. He says:

> "Two methods of improvement suggested themselves. The first consisted, not in increasing the length of the coil, but in using a number of separate coils on the same piece of iron. By this arrangement the resistance to the conduction of the electricity was diminished and a greater quantity made to circulate around the iron from the battery. The second method of producing a similar result consisted in increasing the number of elements of the battery, or in other words, the projectile force of the electricity, which enabled it to pass through an increased number of turns of wire, and thus, by increasing the length of the wire, to develop the maximum power of the iron."[2]

In order to test the first method "a number of compound helices were placed on the same bar, their ends left projecting and so numbered, that they could be all united into one helix, or variously combined into sets of lesser length." So there came into being another magnet, shown in Fig. 2. The magnetic effect was greatly increased. We quote again from Henry:

> "These experiments conclusively prove that a great development of magnetism could be effected by a very small galvanic element; and also that the power of the coil was materially increased by multiplying the number of wires, without increasing the length of each.
>
> "The multiplication of the wires increases the power in two ways; first, by conducting a greater quantity of galvanism, and secondly, by giving it a more proper direction; for since the action of a galvanic current is directly at right angles to the axis of a magnetic needle, by using several shorter wires we can wind one on each inch of the length of the bar to be magnetized, so that the magnetism of each inch will be developed by a separate wire; in this way the action of each particular coil becomes very nearly at right angles to the axis of the bar, and consequently the effect is the greatest possible. This principle is of much greater importance when large bars are used. The advantage of a greater conducting power from using several wires might, in a less degree, be obtained by substituting for them one large wire of equal sectional area, but in this case the obliquity of the spiral would be much greater and consequently the magnetic action less; besides this, the effect seems to depend in some degree on the number of turns, which is much increased by using a number of small wires. (Several small wires conduct more common electricity from the machine than one large wire of equal sectional area: the same is probably the case though in a less degree in galvanism)"

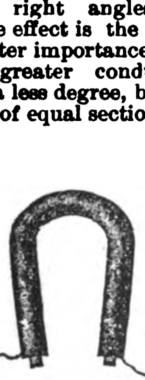


FIG. 1.—HENRY'S "INTENSITY" MAGNET.

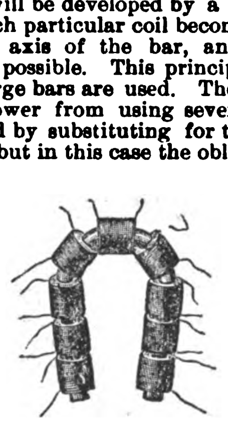

FIG. 2.—HENRY'S "QUANTITY" MAGNET.

In Henry's cabinet were now two distinctly different magnets, one with a long continuous coil of fine wire, wound back and forth on itself; the other with a number of short thick wires; the latter much the stronger. He called the one the "*Intensity*" the other the "*Quantity*" magnet. We will let him tell why he thus designated them.

> "From a series of experiments with this and other magnets it was proved, that, in order to produce the greatest amount of magnetism from a battery of a single cup, a number of helices is required; but when a compound battery is used, then one long wire must be employed, making many turns around the iron, the length of wire, and consequently the number of turns, being commensurate with the projectile power of the battery.

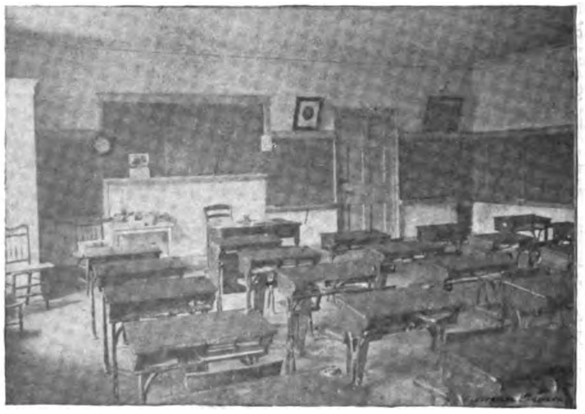

FIG. 3.—ROOM IN ALBANY ACADEMY, ORIGINALLY OCCUPIED BY HENRY.

> "In describing the results of my experiments, the terms *intensity* and *quantity* magnets were introduced, to avoid circumlocution, and were intended to be used merely in a technical sense. By the *intensity* magnet I designated a piece of soft iron, so surrounded with wire that its magnetic power could be called into operation by an *intensity* battery, and by a *quantity* magnet, a piece of iron so surrounded by a number of separate coils, that its magnetism could be fully developed by a *quantity* battery. I was the first to point out this connection of the two kinds of the battery with the two forms of the magnet in my paper in *Silliman's Journal*, January, 1831, and clearly to state that when magnetism was to be developed by means of a compound battery, one long coil was to be employed, and when the maximum effect was to be produced by a single battery a number of single strands were to be used."

The Institute was not insensible to the value of Henry's contribution to science and art, as the young man appeared again and again before the society, each time with magnets more powerful. These were received with enthusiasm and the fame passed beyond Albany to give their maker distinction.

Let us glance at the room that Henry occupied while making these experiments. An item recorded in one of the books of the Academy, Sept. 8, 1826, when Henry entered the Institution as a professor, tells us which room was assigned him, a room which he retained until the latter part of the year 1829: "*Resolved* that Prof. Henry be allowed the use of the South West Room in the third story of the Academy during the pleasure of the Board." This was Henry's work room, school room, lecture room. A long table extended across one side, and from this a series of long benches, rising in tiers one above the other filled the room. The illustration we give, Fig. 3, is from a photograph of the room as it is now, still used as a school room by the Academy.

AN ELECTRIC FREIGHT SERVICE BETWEEN ALBANY AND TROY, N. Y.

The express cars to be used by the Albany City railway company in carrying merchandise between Albany and Troy are equipped with motors and are ready to be placed in use on the road. The company have secured the building at the corner of Broadway and Nineteenth street, West Troy, for a depot, and as soon as an office shall be fitted in the building at the corner of State and Dean streets, Albany, the express line will be put in operation. It is expected the placing of the cars on the road will lead to a lively rate war with the owners of express wagons between Albany and Troy. The cars will commence running about April 1.

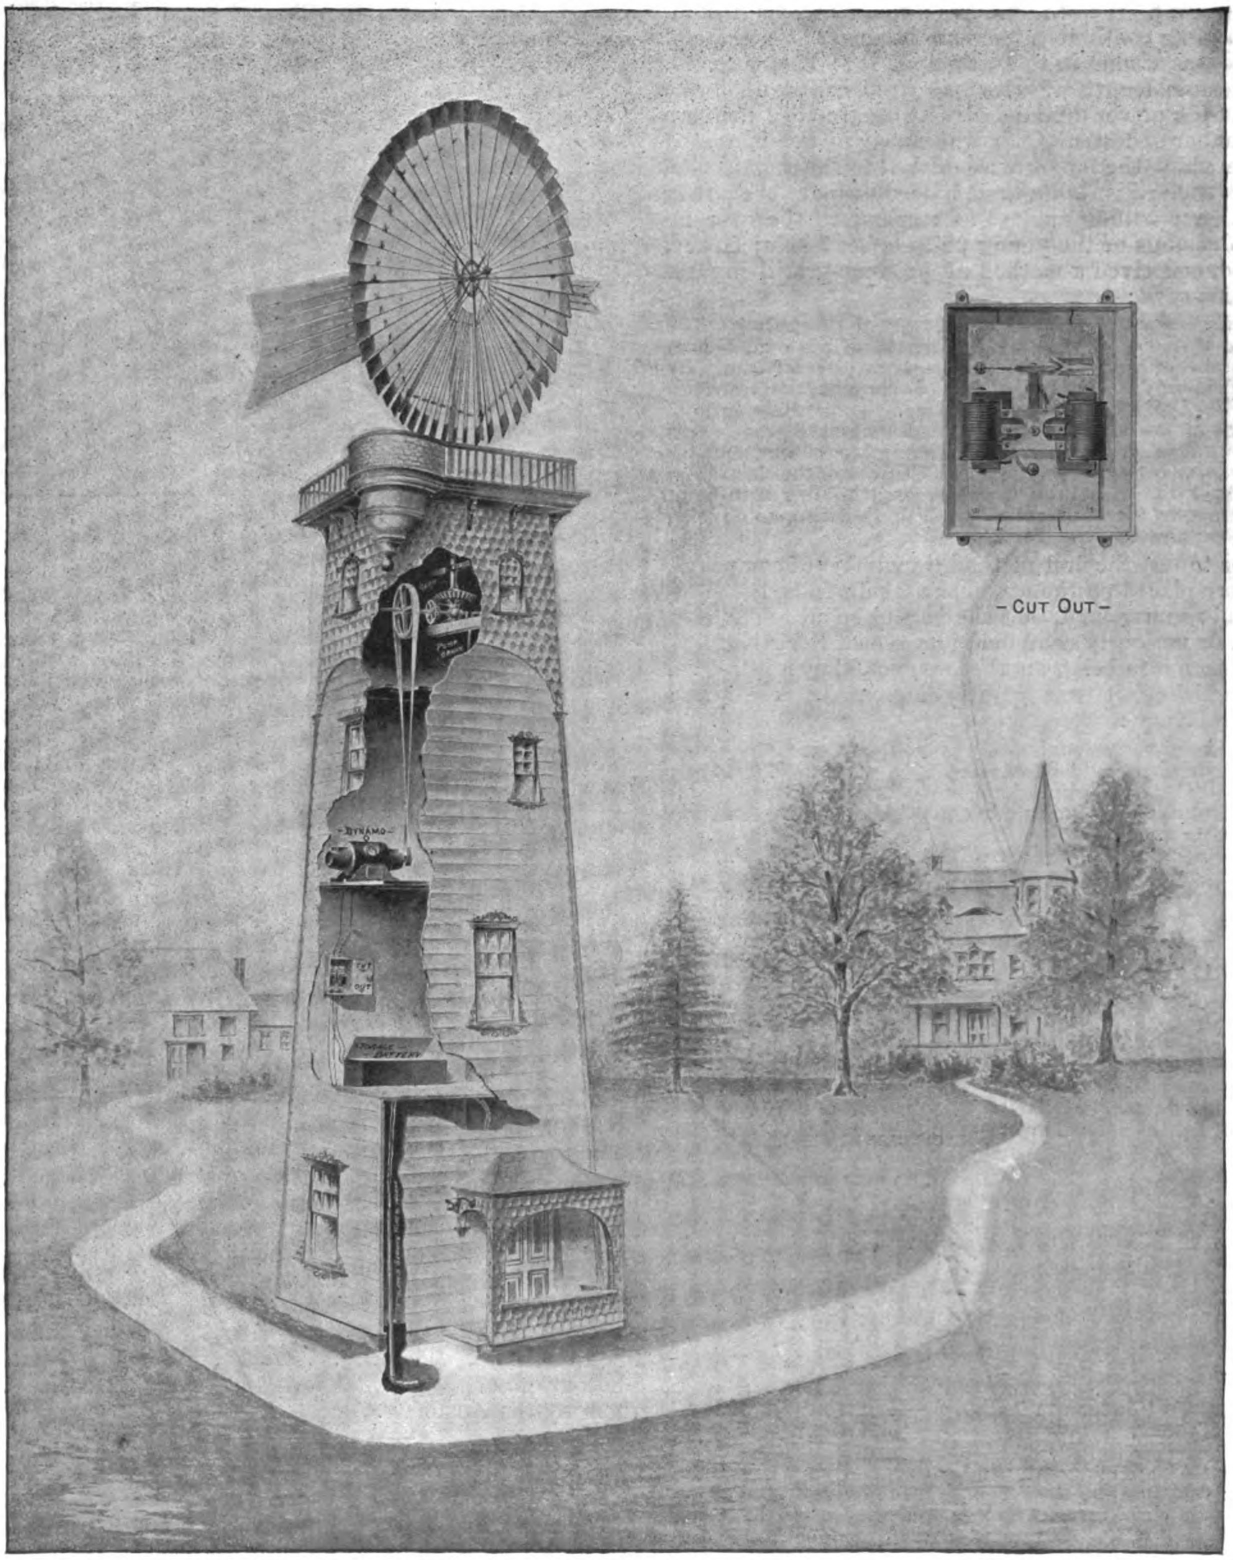
THE LEWIS SYSTEM OF ELECTRIC LIGHTING BY WINDMILLS.

In our issue of Jan. 17 we described the Lewis system of lighting railway cars in which special provision had been made to insure proper working for all rates of speed at which a train moves. Evidently the conditions here involved, so far as variation of speed is concerned, are identical with those obtaining in the operation of windmills, and hence it was but a step, and a very easy one, to adopt the Lewis arrangement to the storage of current generated by wind-power. The problem, indeed, was considerably simplified inasmuch as the arrangement which had to be made in the case of the car lighting system to allow for the reversing of the car's motion, became entirely negligible in the case of the windmill, the motion of which is always in the same direction.

In order to test the practicability of the system, the Lewis Electric Company have installed such a generating plant



The Lewis System of Electric Lighting by Windmills.

in one of the windmills at the works of Mr. A. J. Corcoran, Jersey City, N. J., the well-known builder of windmills, and during a recent visit of the writer to these works the operation of the system was demonstrated to its fullest advantage. The simplicity of the plan is well shown in the accompanying engraving which illustrates such a plant in all its details. The dynamo driven by belt from the main gear, charges a set of storage batteries. It is so designed that throughout the wide variations of speed of the windmill it maintains the potential constant. The automatic switch, which constitutes the only auxiliary apparatus in the entire system, is so arranged as to close the circuit to the battery when the dynamo speed is such as to generate an E. M. F. equal to the counter E. M. F. of the battery. At this point the cells begin to be charged and as soon as the dynamo pressure falls below the required potential, the cut-out acts so as to prevent the battery from discharging through the dynamo. The switch is so designed that it opens and closes the circuit when the current itself is at zero, and hence no sparking occurs at the contact points, while the brushes on the dynamo remain fixed under all conditions of working.

The Corcoran mill at Jersey City has a diameter of 18 feet and at a speed of 20 miles an hour is capable of delivering 3 h. p. The dynamo is driven by belt in the manner shown, having a maximum current capacity of 35 amperes at 35 volts and is cut into action when the speed is 600 rev. per minute, that is, when an 8-mile breeze is blowing. The machine is of the iron-clad type, entirely enclosed and occupies a floor space of only 30 inches square and 15 inches high.

The plant, though merely an experimental one, has operated without a single mishap from the start and the storage cells furnish current for 24 incandescent lamps distributed through the work shops.

The smoothness of working and the evident reliability of the entire arrangement leave little room for doubt that we shall see a wide application of this system.

THE TESLA CONDENSER-MAGNET.

In electric apparatus or systems in which alternating currents are employed, the self-induction of the coils or conductors in many cases operates disadvantageously by giving rise to false currents which often reduce the commercial efficiency of the apparatus or operate detrimentally in other respects.

The effects of such self-induction, as is well known, can be neutralized by proportioning to a proper degree the capacity of the circuit with relation to the self-induction and frequency of the currents. This has been accomplished heretofore by the use of condensers applied as separate instruments. In order to avoid the employment of condensers, which involve additional expense, Mr. Nikola Tesla has devised a method of constructing the coils themselves so as to accomplish the same object as the condensers.

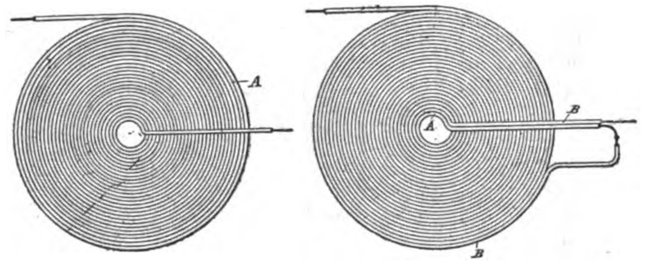
Mr. Tesla had found some years ago that in every coil there exists a certain relation between its self-induction and capacity that permits a current of given frequency and potential to pass through it with no other opposition than that of ohmic resistance, or, in other words, as though it possessed no self-induction. This is due to the mutual relations existing between the special character of the current and the self-induction and capacity of the coil, the latter quantity being just capable of neutralizing the self-induction for that frequency.

It is well known that the higher the frequency or potential difference of the current, the smaller the capacity required to counteract the self-induction; hence, in any coil, however small the capacity, it may be sufficient for the purpose stated if the proper conditions in other respects be secured. In the ordinary coils the difference of potential between adjacent turns or spires is very small, so that while they are in a sense condensers, they possess but very small capacity and the relations between the two quantities, self-induction and capacity, are not such as under any ordinary conditions satisfy the requirements contemplated by Mr. Tesla, because the capacity relatively to the self-induction is very small.

In order to attain his object and to properly increase the capacity of any given coil, Mr. Tesla winds it in such a way as to secure a greater difference of potential between its adjacent turns, and since the energy stored in the coil —considering the latter as a condenser—is proportional to the square of the potential difference between its adjacent convolutions, it is evident that in this way he may secure, by a proper disposition of these convolutions, a greatly increased capacity for a given increase in potential difference between the turns. The accompanying drawings show the general nature of the plan which he has adopted for carrying out this idea

Fig. 1 is a diagram of a coil wound in the ordinary manner, while Fig. 2 shows the winding designed to secure the objects Mr. Tesla is aiming at.

In Fig. 1, A designates any coil the convolutions of which are wound insulated in the usual way. Let it be assumed that the terminals of this coil show a potential difference of 100 volts, and that there are 1,000 convolutions; then considering any two contiguous points on adjacent convolutions let it be assumed that there will exist between them a potential difference of one-tenth of a volt.



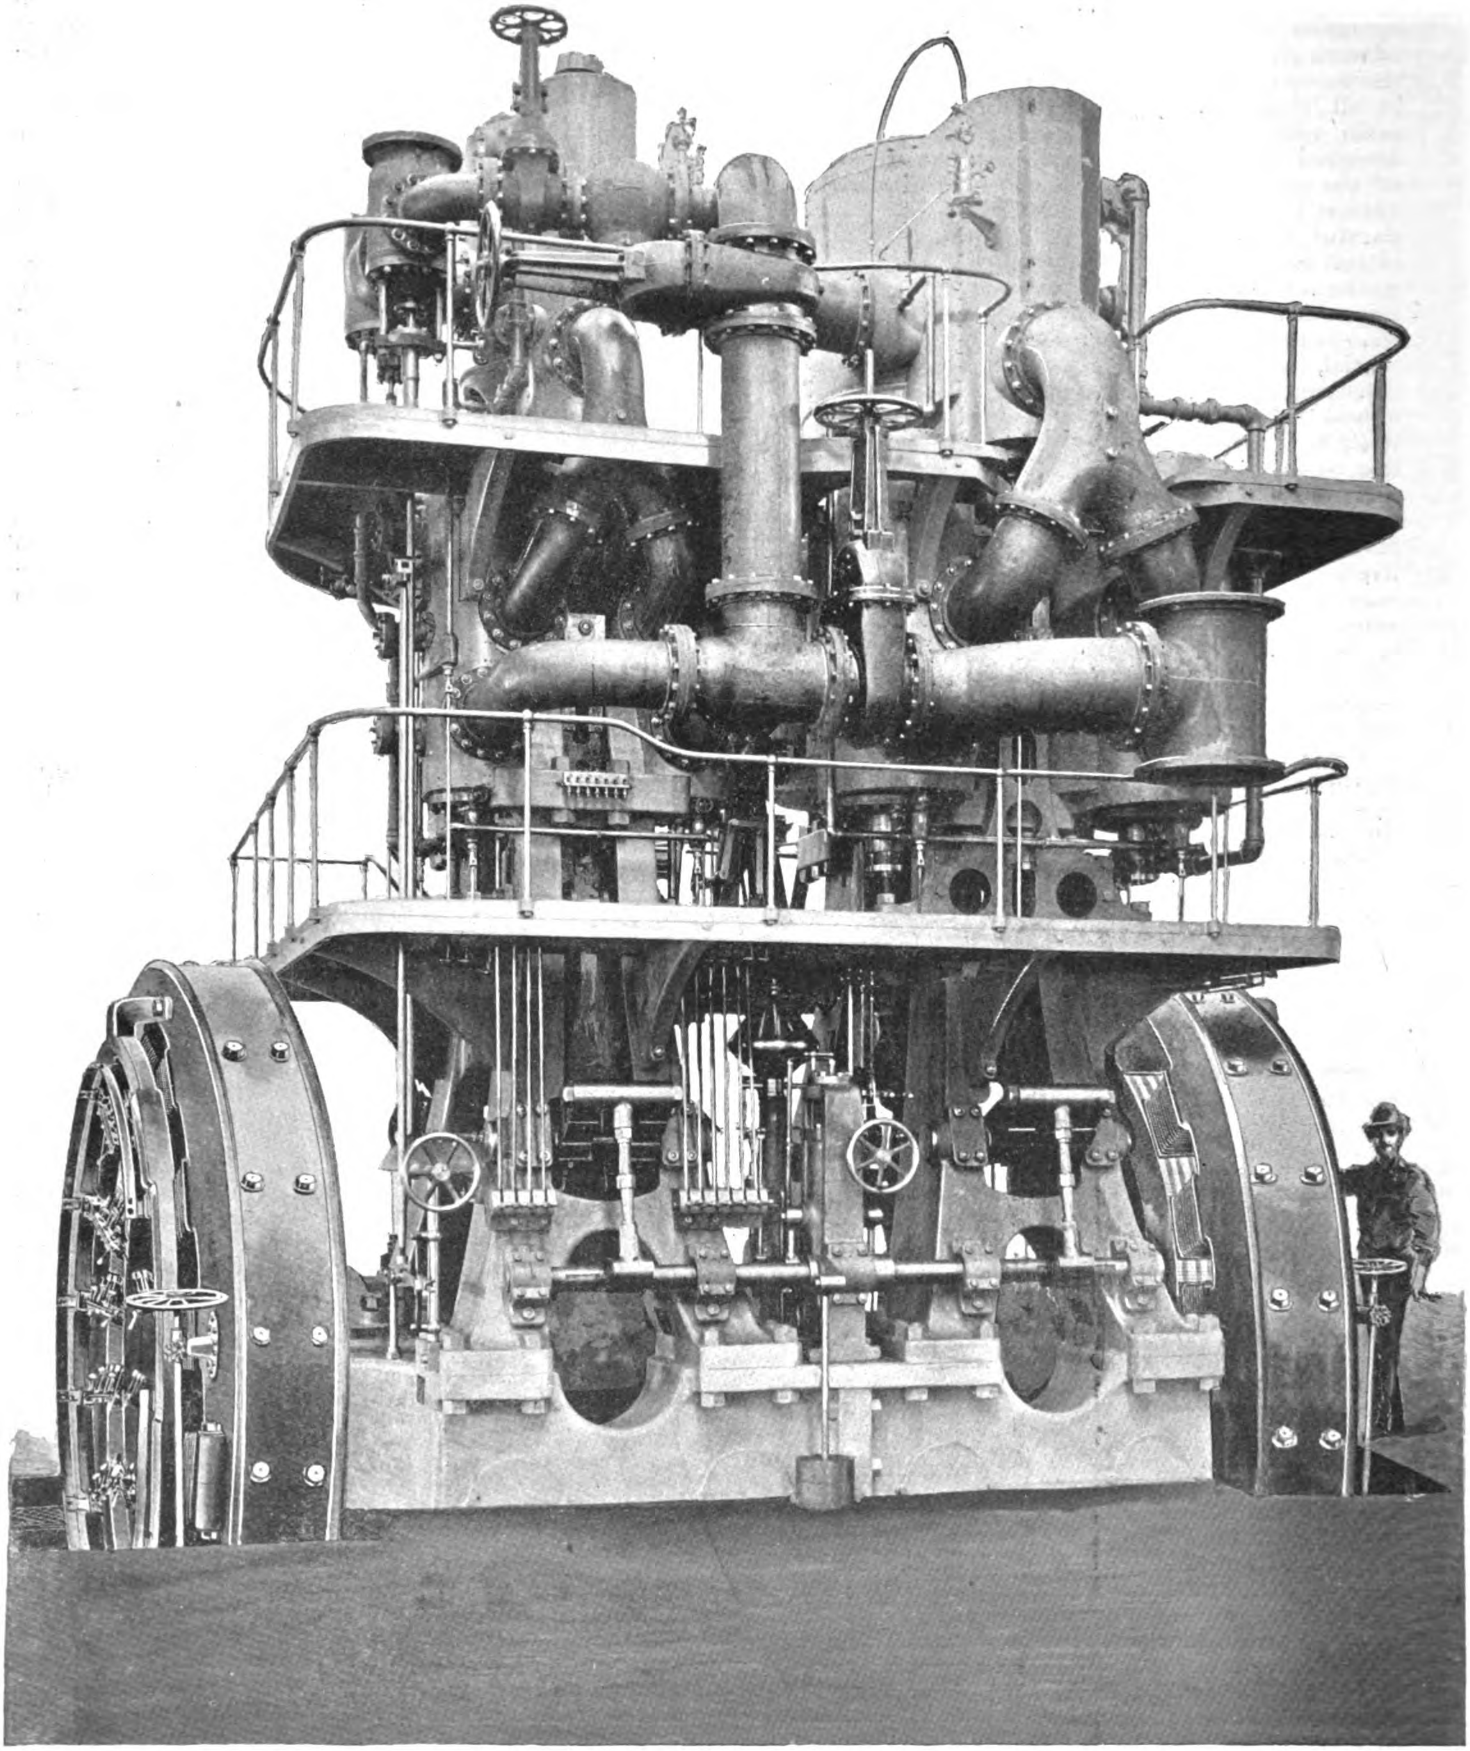
FIGS. 1 AND 2.—THE TESLA CONDENSER-MAGNET.

If now, as shown in Fig. 2, a conductor B be wound parallel with the conductor A and insulated from it, and the end of A be connected with the starting point of B, the aggregate length of the two conductors being such that the assumed number of convolutions or turns is the same, viz., 1,000, then the potential difference between any two adjacent points in A and B will be 50 volts, and as the capacity effect is proportional to the square of this difference, the energy stored in the coil as a whole will now be 250,000 times as great.

Based on this principle, any given coil may be wound either in whole or in part, not only in the exact manner illustrated, but in a great variety of ways, so as to secure between adjacent convolutions such potential difference as will give the proper capacity to neutralize the self-induction for any given current that may be employed. Capacity secured in this particular way possesses an additional advantage in that it is evenly distributed, a consideration of the greatest importance in many cases, and the results both as to efficiency and economy are more readily and easily obtained as the size of the coils, the potential difference, or frequency of the currents are increased.

THE TROLLEY AND INSURANCE.

The New York Board of Fire Underwriters' special committee on electrical hazards called upon Mayor Gilroy recently and protested against the introduction of the trolley upon Manhattan Island, also warning the Mayor that if the trolley was introduced the inevitable result would be an increase in fire insurance rates.



THE NEW VAN VLECK ENGINE AND GENERAL ELECTRIC GENERATORS IN THE ELM STREET EDISON STATION.

THE VAN VLECK 3,000 H. P. ENGINE.

The latest addition to the engineering features of the Edison Electric Illuminating Co. of New York is a very interesting engine of large size which has recently been put in operation at the Elm Street Station. The engine has cylinders 26, 37, 52 and 72 inches in diameter, with a common 36-inch stroke. Its speed is 90 revolutions, and with 200 to 210 pounds pressure it will develop from 2,500 to 3,000 h. p. The engine was built by The Dickson Mfg. Co., of Scranton, Pa. and is directly connected to a pair of 800 K. W. multipolar dynamos, one at each end of the engine. The armatures are placed directly on the overhanging ends of the engine shaft and no "outboard bearings" are employed.

The dynamos were constructed by the General Electric Company, and are the largest low tension direct current machines yet built; and although each machine has only half the capacity of the famous 1,500 K. W. General Electric railroad generators, they compare favorably with the railroad generators in point of size, the diameter over the field ring being 14 feet, and that over the armature 10 feet. The dynamos are of the common external field type with Gramme wound armature, and the commutator is a part of the bar windings on the armature face. Experience has shown that this type of machine is most satisfactory and specially adapted to the practice of omitting the outboard bearings, which are most undesirable when space is limited. They are also in the way when it becomes necessary to remove an armature. The armatures weigh about 24 tons each and alone serve as fly wheels for the engine.

The engine possesses many of the characteristics of the former engines built by the Dickson Company on what is known as the Van Vleck disconnective type. Its essential difference is, however, that it is a two-crank tandem quadruple engine instead of a three-crank triple engine. The selecting of the two-crank design, in lieu of the three crank, was induced principally by the desire to economize in floor space, and the result attained is most noteworthy in that the area occupied by the engine base, including the overhanging bearings, gives about 10 h. p. per square foot. The engine bed itself, exclusive of the projecting bearings, is 14 feet 6 inches long and 13 feet 8 inches wide.

On the other hand, the large 2,500 h. p. quadruple expansion engine, which recently attracted so much attention at the World's Fair, occupied a floor space about 37 feet by 40 feet, and gave therefore only about 1⅓ h. p. per square foot. The World's Fair engine also required a much greater area for the belts to extend over to drive the independent dynamos, whereas in the case of the engine illustrated there are no belts, and both the dynamos only occupy an additional area of 160 square feet.

It is claimed by Mr. Van Vleck, that engines will become more and more compact when engineers realize more fully, that a compact engine can be built at no greater cost and will be just as economical to operate as the engine that occupies several times as much space as is necessary.

In the case of the engine and generator here shown, a very large amount of building and real estate investment is saved and the capacity of the station is very nearly doubled by employing a two-crank instead of a three-crank engine.

The engine, as will be seen, consists of two sets of tandem cylinders mounted on the customary marine A-frames; the "high" and "first medium" cylinders comprise the left hand engine, and the "second medium" and "low" cylinders the right. The piping is so arranged that either the right or left engine can be operated without the other. When the "high" left-hand engine is used alone it exhausts past the "low" or right hand engine; but when the "low engine" is used only, it is supplied with steam past the "high engine," through a reducing valve.

The steam chests are on the engine front, as is the case with all the Van Vleck engines, making a very short engine facilitating the operation of the valves. The "high" and "second medium" cylinders are provided with one valve, and the "first medium" and "low" cylinders with two valves, the lower of which are not placed directly under the upper ones, but on each side so that they can be removed without in the least interfering with the upper valves. This feature is the invention of Mr. J. W. Sargent, M. E., and is a very valuable departure in the construction of inverted cylinder tandem engines.

The valves are all of the well known piston type and are double-ported. They are operated by a well designed Joy valve gear, controlled by a hydraulic governor, which regulates the steam for all four cylinders, and is so arranged that the speed of the engine can be varied while the engine is running. The cylinders are all provided with "liners," and are steam jacketed. The cylinders are also provided with suitable relief, drip and starting valves, which are all controlled by levers placed at the front. The cylinder covers and the piston heads are of cast steel of the marine cone design, which is considered a great advance over the ponderous cast iron piston heads which are still used so much on land.

The engine is provided with a screw and a lever throttle valve, the two placed in series in the main steam supply. The main shaft is of hammered steel and is bored hollow, both through the shaft and crank pins. The shaft is 18 inches at the ends and 16 inches in the centre. It is built in two halves and coupled in the middle. The crank pins are 16 inches in diameter and 18 inches long and are forged solid with the crank blocks. The cranks are provided with counterweights.

The main shaft journals are constructed so that the lower boxes can be removed without lifting up the shaft. The end bearings are 40 inches long, and the two centre bearings are 20 inches long, the employment of the Joy valve gear giving great length of bearings for a given length of shaft. The length of the shaft over all is 28 feet 5 inches.

The height of the engine from the floor line, is 25 feet, and, as will be noted, the engine is provided with two tiers of platform. A very complete system of oil pipes and oil tanks is provided, so as to reduce the labor of oiling as much as possible. The engine can be operated by one engineer and one oiler, and the dynamos need only the occasional attention of a dynamo man. The production of 1,600 kilowatts can therefore be carried on at a very low cost, compared with the old fashioned method of employing numerous small machines.

Most of the important details of the engine were laid out by Mr. J. W. Sargent from the specifications and advice of Mr. John Van Vleck, in consultation with Mr. H. J. Smith and other members of the Illuminating Company's staff. The drip piping, starting valves, and some other details, were worked out by Mr. R. W. Rowley of the Dickson Mfg. Co.

There are installed in the Elm Street Station, two 1250–1500 h. p. triple engines, and two 625 h. p. triple engines on the Van Vleck three-crank type. Three of the 625-engines are also installed at the Twenty-sixth Street Station, and one at the Schenectady Works of the General Electric Company.

The steam piping for the engines at the Elm Street Station has been designed and constructed with great care for a working pressure of 225 lbs. per square inch. It is probably the heaviest piping in the country, and a complete new line of valves and fittings has been especially developed for it, as the ordinary valves and fittings have been found to give a good deal of trouble when subjected to modern high pressure requirements; the adoption of high pressure having been dictated not only from economy, but for the placing of great power in a small space.

OBITUARY.

HEINRICH HERTZ.

The brief mention made in our last issue, of the death of Heinrich Hertz, on Jan. 6, will have called forth feelings of sorrow and regret among all who have followed the later progress in electrical research and application. At the age of 36, Hertz has been removed from a field of activity which he has stamped indelibly with his genius and with which his name will always be connected as a pioneer.

Hertz was born at Hamburg and up to his twenty first year he had devoted himself entirely to engineering, graduating at Berlin, where he shortly afterward took up the study of physics under Helmholtz and Kirchhoff. His abilities were early recognized by Helmholtz, whose assistant he became and with whom he remained until 1883 when he became "privat-dozent" at the University of Kiel. In 1885 he was offered the professorship of physics at the Technische Hochschule at Karlsruhe, and in 1889 he succeeded the celebrated Clausius in the chair of physics at the University of Bonn,—no small honor indeed, and especially in Germany, for a man of 32.

Although his work was by no means confined to the electrical field it is on his electrical investigations that his great fame is founded. His first work to attract general attention was an investigation into the effect of the ultra-violet rays on the electric discharge, published in 1886. In the year following he took up a series of investigations the outcome of which was the wonderful experiments that at once made his name famous and that offered the long sought for experimental demonstration of the wave lengths, and the speed of propagation, of electric vibrations, and their identity with luminous vibrations.

It is rare, indeed, that a work so fundamental in character as that of Hertz has found the immediate and universal acceptance which was accorded to it, but the logic of Hertz's arguments and the experimental proofs left no room for doubt or hesitancy. Great as has been the influence of his work in the short period which has elapsed since its promulgation, the importance of its ultimate results can scarcely be overestimated.

PERSONAL.

MR. J. M. MOFFATT, E. E., formerly in charge of Western Union quads and of subway tests, from "195," is now the electrical engineer of the Erie and Wyoming Valley Railroad Company, with his headquarters at Dunmore, Pa. He has charge of all their telegraph, telephone and electric light and power work, for which his long experience and wide reading eminently fit him.

ELECTRIC WINDMILL PLANTS.

THE utilization of what are termed the waste forces of nature is steadily pushing itself to the front, and engineers have been compelled to study applications which were scarcely even contemplated ten years ago. The ready means which electricity places in the hands of the engineer have not been overlooked and as soon as the storage battery became a commercially available apparatus a new impetus was given to the realization of long-meditated schemes. The first of these ideas to be taken up seriously was the transmission of the powers of water falls, the progress in which presents a remarkable record, of which our readers have been kept well informed. These powers, from their uniform and steady nature, afforded a favorable opportunity, but the intermittent powers of nature such as the rising and falling tides, the waves, and especially the wind, have up to the present absorbed the attention of but a few isolated workers, or indeed enthusiasts, and schemes for their utilization have been looked upon by engineers as more in the nature of fads, than as legitimate engineering work worthy of close and serious investigation.

Leaving out of consideration the utilization of the tides and waves, it seems worth while to inquire whether the power of the wind cannot be employed for the generation of electric current?

We venture to say that few have ever stopped to consider the great and rapidly increasing number of windmills now in operation and the work they are doing, principally in elevating water for drainage, irrigation, and domestic purposes. Their number in this country alone runs into the tens of thousands, and the size and powers called for are constantly increasing.

Among the very few who have taken up the utilization of wind power for electrical generation are Mr. C. F. Brush, of Cleveland, Ohio, and Prof. Blyth, in England, the former of whom, especially, has fitted up quite an elaborate plant. It must be evident however, that if this method of operation is to come into general use it must be reduced to the simplest possible arrangement, and to lack of this important feature of simplicity may be attributed the reluctance hitherto manifested by manufacturers as well as users to embark in this work. The three elements upon which success in this field depends, that is, the windmill, the dynamo and the storage battery, will be conceded to have all arrived at that stage which is called commercial, so that there can be no further question as to reliability. The only other factor then is the wind itself and on this point also sufficient data are at hand to base calculations upon. While the maximum and the minimum rate, of course, vary during different hours of the day and with the locality, an average rate of 7½ miles per hour can be depended upon in the United States. Near the sea coast and in elevated localities the average rate is much higher and it is in such situations that we shall probably see the first attempts made to apply the plan. The simplicity of the methods embodied in the Lewis system, described elsewhere in this issue, will go far towards bringing about a trial of this method by many who have long looked for an outfit of this kind that did not require the services of an expert mechanic and electrician.

A NEW PHASE IN INCANDESCENT LAMP LITIGATION.—THE BEGINNING OF THE END?

If the framers of Section 4887 of the Revised Statutes—now so familiar to our readers—had taxed their brains to imagine all possible consequences of that absurd provision, they would certainly never have hit upon the state of affairs created by Judge Ricks's opinion of last week, dissolving the injunction upon the Buckeye Electric Company, granted last July in the suit of the Edison Electric Light Company (General Electric Company). The decision is printed in full elsewhere in this issue. It sets the Buckeye company free at once; it seems not to be appealable, but may go to a final hearing of the suit before Judge Ricks some time in the future, with small, if any, likelihood of a different outcome. The Court did not pass upon the question of the expiration of the United States patent November 10, 1893—the end of the term of the English patent—nor did it consider the legality of the action of the Patent Office in affixing to the patent, upon the petition of Edison and the Edison company, in 1883, the correction reciting previous foreign patents and limiting the term of the domestic patent by that of the foreign patent having the shortest time to run; but, says Judge Ricks: "*Whether the Patent Office was authorized by law or not to make such official correction, the petitioners unquestionably had the legal power to voluntarily fix a limit upon the duration of their own patent.*" Further, the Judge says:

> "But the public, and those interested in the duration of the patent, had the right to accept complainants' statements as to the date of those foreign patents, and to act accordingly."
>
> "The application for the Edison Patent was filed Nov. 4, 1879, and the patent was granted Jan. 27, 1880, so that by the admissions of their petition the British Patent was both applied for and granted between those dates and expired between Nov. 10, 1893 and Jan. 27, 1894. The complainants cannot object because the defendant acted upon those representations. If complainants had taken no action whatever, but had relied upon their legal rights as they might be subsequently defined, the public would have acquired no advantages by the proceedings now under consideration. The defendant would have acted at its own peril, and have had no claim such as they now assert. The complainants' conduct and public declaration of the facts concerning their patent are binding upon them, and they cannot now be heard to say that they were made in doubt as to their legal rights, and made in such uncertain terms as to put the defendant upon examination as to the facts and the law, and to be bound by its proper interpretation of them."

The Court thus holds that, whether the Edison patent had or had not any legal existence after November 10, 1893, as against the Buckeye company it is of no avail after that date, the defendant having taken the voluntary act of the complainants, limiting their monopoly by that date, in good faith, and having acted upon it in planning their business and increasing their investment of capital in the manufacture of incandescent lamps.

It is difficult to see why the same reasoning will not apply in the cases of other lamp manufacturers, many of whom are in a position similar to that of the Buckeye company in respect to the merits of the question determined by Judge Ricks. The Buckeye Electric Company has been the first to bring that question to an issue in court. It has thus freed its own hands and established a precedent that may reasonably be expected to benefit all other lamp makers, to say nothing of its indirect benefit to all branches of electrical industry related to electric lighting.

The Electrical Engineer likes to see meritorious patents and obvious rights maintained at all times, but has never entertained the opinion that the suppression of all incandescent lamp making, except that of the Edison company and its successors, would be just or equitable under the circumstances of the Edison patent. We have before directed attention to the *obiter dictum* of Judge Wallace, July 31, 1891, on the occasion of settling the terms of the decree in the case of the United States Electric Lighting Company. Referring to the vagueness of the patent,

> His Honor said he thought that the greatest cloud that hung over the patent was in its claims—in the language of the patent itself. He did not much blame any infringer for assuming that he could go on and make any sort of an incandescent lamp without fear of that patent. . .

That remark of the Court, nearly three years ago, doubtless fairly represented the opinion of the patent held by the people who had put their money and brains into the manufacture of lamps in competition with the Edison company. Moreover, the long term of years which the Edison company suffered to pass without action in enforcing their claims created a presumption against the patent.

The effect of Judge Ricks's opinion is to declare the Edison patent inoperative after November 10, 1893, not because under Section 4887 it expired on that date, but because its owners said it would, and solemnly notified the public, over ten years ago, that the patent would expire then and allowed that notice to stand nearly ten years.

Section 4887 cuts a figure at every stage of the proceedings taken by the Edison people—in filing their petition of 1883 to the Patent Office, requesting the limitation of the patent, and in their petition of last March for the cancellation of their former action—while the decision of Judge Ricks is quite outside of any interpretation of that inconvenient and troublesome statute.

ELECTRICAL "PRIVATE VIEWS."

The workings of no kind of public service are so little understood by the public, even in these days when everything is written up in popular form, as those employing electricity. This is notably the case with the telephone exchange service. Misconceptions are very common as to the apparatus and employees that come in between the parties to telephonic conversations. Any intelligent effort to remove some of these misconceptions is to be applauded, and an interesting example comes to hand in the novel policy recently inaugurated by the management of The Metropolitan Telephone & Telegraph Company in inviting its subscribers and their friends to view the new central office in Broad St., New York. A few days after the exchange was opened a general invitation was issued to the Broad street subscribers. During the two afternoons appointed nearly 500 telephone users made a tour of inspection under the guidance of the company's staff. The usefulness of such an object lesson was abundantly illustrated by the comments of the visitors, most of whom were entirely unprepared to encounter such a display of highly finished and intricate apparatus, or such a numerous and industrious operating force. Many subscribers resolved on the spot, after watching an operator handle half a dozen calls in ten seconds, never to swear at "central" again, and some even declared that they would cease grumbling about the rates, so obvious did it appear that there really were other items in the cost of telephone service besides the set of instruments at the subscriber's station.

THE TELEPHONE PATENT SITUATION.—III.

The telephone receiver being free and a non-infringing transmitter possible, how may the the telephone be supported on its hook without infringing one or more of the telephone switch patents? There are more than one hundred patents on telephone switches, a large proportion of which are upon automatic switches and supports. The Bell company has had seventeen years' possession of the telephone field in which, leisurely and carefully, to make experiments, take out patents of its own and purchase the patents of others at practically its own price. In no department of the art, perhaps, has the company shown greater skill and better judgment than in the protection of the automatic telephone support. The most famous of the support patents, if not the most inclusive, is that of Hilborne L. Roosevelt, dated May 27, 1879, and numbered 215,837. This patent covers broadly the class of telephone supports by which the relations of circuits are changed through the action of the weight of the receiver when upon its support, against a spring—the circuit being in one condition when the telephone is in use and in another when it is hung up. The claims of this patent are as follows:

1. The combination, with a telephone, of a circuit closing or changing portion and screws or points, the circuit-closing portion being arranged to be placed in contact with one screw-point through the influence of the telephone when not being used, and to be placed in contact with the other screw or point when the spring is freed from the influence of the telephone, substantially as described.

2. The combination of a spring-switch, connecting-wire connected therewith, and a transmitting-instrument suspended thereto, substantially in the manner described, whereby the raising of the transmitting-instrument causes the spring-switch to make or break or alter the electric circuit.

3. The combination of a spring-switch and connecting-wire connected therewith, and a transmitting-instrument suspended thereto, combined and connected together, substantially as herein described, whereby a circuit is made through a signaling-instrument when the weight of the transmitting-instrument is on the switch, while the circuit is closed through the transmitting-instrument itself when its weight is removed from the switch.

4. A transmitting-instrument hung on a spring-switch, which spring-switch has two points, the lower one dead, the upper one making a contact with the ground, combined with another transmitting-instrument suspended on a similar switch, which switch has its lower point connected with a signaling-instrument, and its upper point connected to the transmitting-instrument, substantially as described.

5. The combination of a suspended transmitting-instrument, spring-switch, and connecting-cord independent of the connecting-wires, whereby the weight of the transmitting-instrument is taken from the wires, substantially as described.

6. The combination of two telephones, connecting-wire, and battery, and two spring-switches, connected and combined substantially as described, whereby when the weight of the telephones rests on the spring-switches a through-circuit is made by means of the battery through the signaling-instrument, while when the telephones are raised a circuit is made through the telephones and the battery is cut out.

7. The combination of a connecting-wire carrying an electric circuit, and attached to the spring-switch having contact-points, and a transmitting-instrument suspended to said spring-switch, connected and combined substantially as described, whereby the weight of the transmitting-instrument upon the switch causes the switch to complete a circuit through itself, and to a ground or a signaling instrument, while when the transmitting-instrument is raised a circuit is made through said transmitting-instrument.

8. A telephone having two connecting conducting-cords and one suspending non-conducting cord, the said non-conducting cord being shorter than the two conducting-cords, whereby the weight of the telephone is taken from the conducting-cords and rests upon the non-conducting cord, substantially as required.

The patent of which the claims are quoted above has but two years to run from May 27, 1894—or in other words, it will expire on May 27, 1896. In the most important claims of this patent—the first, second, third and fourth—the term "transmitting instrument" is employed instead of "telephone" in all but the first claim. The intention of the patent, however, is entirely clear and it is doubtful whether splitting hairs on the part of those who would infringe or evade the patent on this ground would be successful before a Court. The next important and broad patent upon telephone support switches is that of Geo. M. Phelps, of December 2, 1879, numbered 222,201. It will be noticed that while there are only three claims, no words are wasted, and the claims cover absolutely all that class of telephone supports in which a circuit-changing telephone switch is operated positively in both directions by the removal from, and replacement of, the telephone in its support. There are many subsequent patents subsidiary to this one just as there are many patents subsidiary to Roosevelt's. The following are the claims in full of the Phelps patent:

1. A circuit-changing telephone switch-lever actuated positively in both directions by the removal from or replacement of the telephone in its support, substantially as hereinbefore set forth.

2. The combination, substantially as hereinbefore set forth, of the telephone supporting hook, the pivoted forked switch-lever, and the circuit-changing switch-pieces or contact-springs mounted thereon.

3. The improved telephone-switch hereinbefore described, consisting of the combination of the supporting-hook, the pivoted forked switch-lever, its contact-springs, and the circuit-wires, whereby the circuit-changing is positively controlled by the removal from or replacement of the telephone in its support.

The next stroke of genius on the part of the Bell Company—or rather Western Electric Company—in the matter of supports was in securing control of the patent of Ezra T. Gilliland, of May 31, 1881, No. 242,195. After the patents of Roosevelt and Phelps there seemed to be only one important variety of hook to be covered, and that was the fixed hook in which the telephone when supported was shunted out of circuit by the mere contact of the eye carried by the receiver with its support when hung thereon. The claims of this patent, however, do not seem to be quite so inclusive as those of its two predecessors. There are forms of hook support not covered by these claims, which, it would seem, might as well have been included as not. The claims are as follows:

1. A telephone apparatus comprising, in combination with a telephone and its support, one or more contact-pieces carried by the telephone and electrical connections, as indicated, whereby, when the telephone is on its support, the current passes through the latter without passing through the telephone, substantially as described.

2. The combination of a telephone, an eye or equivalent device carried by the telephone and electrically connected with one or both the binding-posts, and a supporting hook or pin, substantially as described.

3. The combination of an electrical circuit, a transmitter, a hand-telephone, a support for the hand-telephone, a contact-piece carried by the telephone, and electrical connections, substantially as described, whereby the hanging of said telephone on its support cuts both itself and the transmitter out of the circuit, as set forth.

4. A telephone provided with an eye or equivalent device electrically connected with one or both binding-posts, as set forth.

It will be noticed that a telephone carrying a contact piece which is not in electrical connection with either of the binding posts is clear of the second and fourth claims. Again, if the telephone so arranged hangs upon its support in such a manner that the current is divided, say, equally between the support and the telephone, the device is also obviously clear of the first claim, which definitely specifies that when the telephone is on its support the current passes through the latter without passing through the telephone. In order to be clear of the remaining hook patents, however, the transmitter used must employ no induction coil for the reason that the device would then fall under the shadow of the great patent of Thomas A. Watson, of January 9, 1883, No. 270,522, the claims of which are as follows:

1. In combination with suitable contact-points and springs electrically connected with the *call-circuit* and the primary and secondary circuits of a transmitter, the latter circuit including the hand-telephone, a lever electrically connected with the main line in a telephone-circuit, substantially as described, to bring in the hand-telephone and transmitter and *break the call-circuit*, or to cut out the hand-telephone and transmitter and establish the *call-circuit*, accordingly as the lever is moved in one direction or the other.

2. In combination with suitable contact-points and springs

electrically connected with the call-circuit and the primary and secondary circuits of a transmitter, the latter including a hand-telephone, a lever electrically connected with the main line and provided with a hook to support the hand-telephone, and a spring tending to overcome the weight of the hand-telephone, substantially as described, to bring in the hand telephone and transmitter and break the call-circuit, or to cut out the hand-telephone and transmitter and establish the call-circuit, accordingly as the hand-telephone is removed from or hung upon said hook.

3. In combination with suitable stops connected with the primary and secondary circuits of a transmitter, the latter including the circuit through the hand-telephone, a lever electrically connected with the main line and adapted to support the hand-telephone, and provided with a spring tending to overcome the weight of the hand-telephone, substantially as described, to complete the local circuit through the transmitter, and at the same time connect with the main line the secondary circuit through the transmitter and hand-telephone by taking the hand-telephone from the hook.

4. In combination with a magneto-generator, a main-line telephone-circuit and a shunt-circuit passing through the magneto-generator, the push-button U to break the shunt-circuit, substantially as described.

5. A switch-lever and contacts for connecting with the line-wire either a telephonic circuit or a call-circuit, according to the position of the switch-lever, in combination with the magneto-generator, its shunt and push-button, the said magneto-generator being connected with the call-circuit, substantially as described.

6. In a telephonic circuit, the spring-hook D, adapted to support the weight of the hand-telephone, in combination with the contact-springs s^1, s^2, and s^3, connected with the transmitter hand-telephone and a signaling-circuit, substantially as described, for the purpose specified.

7. In a telephonic circuit, the spring-hook D, adapted to support the weight of the hand-telephone, in combination with contact-springs s^1 s^3 and their connections, substantially as described, to automatically establish the primary local circuit through the transmitter, and at the same time bring into the main line the circuit through the hand-telephone and the secondary circuit through the transmitter by taking the telephone from the hook.

8. A switch-lever connected with the main line of a telephonic circuit and movable in either direction, in combination with the contact-springs, s^1 s^2 s^3, the transmitter, the hand-telephone, a signaling-circuit and suitable connecting-wires, substantially as described.

This patent, especially in connection with those of Roosevelt, Phelps and Gilliland, has been responsible for many sleepless nights to many inventors. The first claim of the Watson patent would seem to be especially productive of insomnia. The specifications and drawings would indicate that an automatic switch only was intended to be covered, yet in the first claim the inventor seems absent-mindedly not to have mentioned the fact. Those inventors and manufacturers who are preparing to go into the telephone business and who propose to use magneto call-bells may profitably direct their attention to the 4th and 5th claims of this patent.

In connection with the subject of support patents, a good story is told of an enthusiastic inventor who called recently at the office of an electrical journal, asking the opinion of one of the staff upon his invention. The newspaper man complimented the inventor upon his ingenuity but observed, "I see that you use an automatic gravity switch which, if placed upon the market, will infringe the Roosevelt patent; I would suggest that you change your device so that it will be clear of this patent and also of the other patents upon telephone supports." "Very good," the inventor replied, "I shall do so; this evening I shall take up the matter and think it over." "If you can spare the time," suggested the newspaper man, "you might think it over a little to-morrow evening also."

NOTE.—In the first section of this article [ELECTRICAL ENGINEER January 17, p. 45] Phelps's telephone patent was referred to as No. 222,201, Dec. 2, 1879. The reference should have read: No. 220,209, Sept. 30, 1879.

ELECTROLYTIC POLARITY TEST PAPER.

WE have received from Dr. Durand Woodman, analytical and technical chemist, No. 80 Beaver street, New York, some strips of electrolytic test paper for determining the polarity of electric circuits. The current from two or three Leclanché cells, or say, a a potential of about 4 volts up, is sufficient to produce a violet red color at the negative pole. Specimens of this paper can be obtained from Dr. Woodman.

SYSTEMATIC NOMENCLATURE.

A LETTER appearing in *Nature* by Prof. Geo. F. Fitzgerald and Mr. F. T. Trouton contains the following interesting remarks on the above subject.

If once for all some system of termination was settled upon (as in chemistry, for the increasing oxidation results, &c.), the coinage of words as fresh needs arose would proceed automatically on rational lines.

This might very well form the object of a special committee of the British Association.

Mr. Oliver Heaviside's system for electromagnetic matters has much to recommend itself for adoption, also, in general physics.

For example, after the plan (1) conduc*tion*, (2) conduc*tance*, (3) conduc*tivity*, we would have, in the case of radiant energy, (1) radia*tion*, (2) radia*tance*, (3) radia*tivity*.

The first is for reference in a general way to the phenomenon in question; the second refers to its amount in appropriate units in any individual case; while the third is suitable for expressing the peculiar action or factor in the phenomenon possessed by different *kinds* of bodies. Thus the radia*tance* from a hot kettle would be the total quantity of energy lost per second. The radia*tivity* would be the quantity of this per square centimetre.

With a view of examining the feasibility of this system, the following list is subjoined. Many of the words appear at first as if they would prove most awkward in practice, but remembering similar fears (which subsequently proved groundless) in electromagnetic matters, one is afraid to say they are due to more than unfamiliarity.

Phenomenon	Amount of	Coefficient of
Absorption	Absorbance	Absorbivity
Attrition	Attritance	Attritivity
Diffusion	Diffusance	Diffusivity
Emission	Emissance	Emissivity
Expansion	Expansance	Expansivity
Extension	Extensance	Extensivity
Friction	Frictance	Frictivity
Gravitation	Gravitance	Gravitivity
Heat	Heatance	Heativity
Inertia	Inertance	Inertivity
Polarization	Polarizance	Polarisivity
Reflection	Reflectance	Reflectivity
Refraction	Refractance	Refractivity
Rotation	Rotatance	Rotativity
Solution	Solutance	Solutivity

Special attention deserves to be called to inertance as a good name for mass, and inertivity for density, to rotatance for moment of momentum, and rotativity for moment of inertia.

"ON THE EDGE OF THE FUTURE"—THE VISION OF PROFESSOR HOUSTON.

As regards the future of electricity as an economical agent, Prof. Edwin J. Houston in the January *McClure's Magazine* says:

"In the nearer foreground I see a practical method for the production of electricity directly from the burning of coal. This achieved, there necessarily follows the universal adoption of the electric motor as a prime mover; the relegation of the steam engine to the scrap heap, and the almost immediate realization of the airship as a means of transportation.

"Assuming the cause of chemical affinity to lie in the unlike electric charges of the combining atoms, I see the practical realization of electric synthesis, whereby wholesome food products will be directly formed under the potency of electric affinities. I see, too, a marked advance in electro-therapeutics, whereby human life will be prolonged and its sufferings alleviated. Diagnosis and prognosis will be profoundly aided by exact electrical measurements of the various organs of the human body as regards their electromotive force and resistance. The electro-therapeutist of the future will employ electric charges and currents for restoring the normal charges and currents of the body, as well as for the stimulation of nervous or muscular tissues.

"Back of these achievements I discern a practical apparatus for seeing through a wire—i. e., a device for looking into a receiver at one end of a metallic wire and seeing therein a faithful reproduction of whatever optical images are impressed on a transmitter at the other end—even though thousands of miles intervene. I see the possible use of the step-down transformer for the preparation of a road bed or road surface by the vitrification, in situ, of clay or other suitable soil, by the intense heating power of enormous currents of electricity.

"These things I believe I see with fair distinctness. In the further background I faintly see, dimly outlined through the clouds, an apparatus for the automatic registration of unwritten, unspoken thought, and its accurate reproduction at any indefinite time afterward."

This dream of man's future is full of brightness.

MISCELLANEOUS.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.—VII.

BY PROF. GEORGE FORBES.

(*Discussion.*)

Mr. J. Swinburne said the first thing that struck him on reading the Paper was not a purely electrical question, but a commercial one, and that was, what was this power going to cost? What was it going to be sold at, who wanted it, and what were they going to do with it? The cost of the power was not given in the Paper. In time it must become public property, and he could not be asking Prof. Forbes any secret, because villages and cities were being built and factories started, and he hardly imagined the 'cute Yankee was ready to build villages and start factories without knowing what the power was going to cost. This was rather a curious question, and a rather surprising one when they went into it. In most industries the power used was quite a small proportion of the cost of running a factory, whatever it might be. In others, of course, it was a very large proportion. But in such cases, for instance, as flour milling, the cost of power was really a very small proportion, and it would hardly pay to remove a flour mill to a place where power could be had cheap from a place where labor was cheap. In other cases, such as tearing up wood pulp, of course the cost of power was a much more serious matter. But in dealing with very large power plants it generally came out, unless the load factor was very good indeed, that the cost of coal was not such a serious item as they might expect. Some time ago he worked out a scheme for transmitting power from the Midlands to London, and he found it was very largely a matter of interest, for he found that the interest upon capital was so enormous when compared with the cost of coal that the cost of coal was hardly a factor to be considered at all. There was also another important question in connection with this. They wanted to know who was going to use the power. The problem was entirely different according to whether they wanted to supply small users who required one tenth of a horse power, or to run printing machines in a district like Fetter-lane, with 2 or 3 H. P., or to drive aluminum works, where they would want hundreds or thousands of horse-power. The difficulty with medium powers was to start the motors. That did not come in with large powers; it was a small detail then. Referring to the extra output from a double current, there was something in that undoubtedly, and as a matter of interest he would like to mention that the question of the transmission of power for long distances by means of double alternating current was really before electrical engineers as early as 1887. He had nothing to do with it himself, so he had all the more pleasure in mentioning that at Messrs. Crompton's they had an inquiry for a large power transmission in Australia, and they discussed a method and decided that it should be alternating. Mr. R. B. Rogers, then his (Mr. Swinburne's) assistant, suggested that the right way to do it was by double current, winding the armature all over with wire. In fairness to Mr. Tesla and others he must say that he did not think Mr. Rogers realized that this double-current plant would be self-starting, but he quite realized other advantages. But the extra output, which was one of the features mentioned by Mr. Rogers, with a little illusory when they dealt with very large machines. The next thing he ought to remark was the very high infrequency which Prof. Forbes used, an infrequency of 0.04 sec. per period. He would like to add to what Mr. Mordey and others had said about transformers. Everybody who had done much practical designing would wish to protest against the large amount of general statement in the Paper "all other things being equal," and so on. The whole gist of the matter was in the "all other things being equal." In making a radical alteration such as that the whole comparison turned on the "other things." He protested also against the introduction into a scientific Paper of "well-known facts." Whenever an author said a thing was a well-known fact he was sure to be wrong. As to the flickering of lights, one rather important point ought to be threshed out. Helmholtz was the first, he believed, to investigate the frequency which worries the eye; whether Helmholtz quoted or investigated he was not sure. Helmholtz was concerned with the frequency that worried the ear, and went on from that to the frequency that worried the eye, which he found to be a frequency of 25. It must be borne in mind that the frequency of the flickering in the lamp was always double the frequency of the current, so that would mean, according to Helmholtz, that the eye would stand an alternate current frequency of 12½. It was very curious that Helmholtz's and Forbes's results did not agree. Prof. Forbes observed a flickering at a frequency of 48, or a frequency in the lamp of 96, whereas Helmholtz said the point of limit was 25, so that there was a very large discrepancy between the observations of electrical engineers and the observations of Helmholtz. As to capacity, Prof. Forbes took a great deal of trouble to eliminate capacity from his system. He (Mr. Swinburne) could not help thinking he was wrong there. As soon as Prof. Forbes had in all these triple and double-current motors he would find he had a whole lot of consuming devices on his circuit to take up lagging current. Capacity in the mains was very much like putting a redressed circuit round the field-magnets. Mr. Crompton and he went into the question of frequency some years ago, and they advocated about the same frequency as Prof. Forbes—about 20. But on looking into the matter they found they were wrong. In the first place, the transformers came out outrageous. In the second place, a point which Prof. Forbes had not mentioned, there was the heating of the field-magnets. If they were going to use very low frequency their pole-pieces would be very broad; the peripheral angle covered was large, and if the pole-pieces were not laminated they would get very hot. If they were laminated in the direction of movement they got over the difficulty of heating due to the Foucault currents in it, but they did not get over the difficulty of the enormous hysteresis loss, and he was not sure that this was not going to be a serious difficulty.

Mr. S. F. Walker said with reference to the winking of incandescent lamps, if they used thick filaments they could make the frequency as little as they pleased. He would like to know what the cost of the culvert which Prof. Forbes described was going to be. It appeared to him that town distribution would have to come to that. At present they buried their cables, and they could not be certain what was going to happen to them. Sooner or later faults would be generated; experience in connection with telegraph lines would bear that out. Therefore, he felt confident that sooner or later subways would have to be made for town work, and the conductors would have to be carried so that a man could walk upright and examine them. Of course, the subways might be used for a good many other things. The only question was one of cost, and it was important to know what that would be. The revolving parts in Prof. Forbes's dynamos were very heavy, and the speed seemed to him to be high. He had followed the designs for the bearings and so on very carefully. They could provide for the speed, for the centrifugal force, and the twisting strain on the spindle, which was a most important matter, but there was a big difficulty when they came to provide a steel spindle which was very large, as it would have to be to stand the enormous twisting strain; they could never be quite certain what they got inside. He believed he was correct in saying that, in this country, at any rate, all machines which had such heavy moving masses as this revolved at a very much lower speed, something like one-tenth.

Mr. Ferranti said it was well known that dynamo contractors and designers from all the world over had submitted plans to the Niagara Company. It seemed to him that it would be very hard to design a dynamo which was not in every way the best from the knowledge which the gentlemen of the Cataract Construction Company had had put before them. There were, however, several important features in which the dynamo proposed was novel. One of them was the method of insulating the coils. He had not heard of any other public proposition except that of Prof. Forbes for doing it in that way. It might be interesting to know that in the provisional specification of a patent he (Mr. Ferranti) had abandoned, occurred a passage describing a very similar arrangement. He let that drop, and he thought wisely so. He had had the pleasure lately, even since the last discussion, as well as before the Paper was read, of going round some of the works on the Continent, much as Prof. Forbes and the other engineers of the Cataract Construction had done. Although he thoroughly disagreed with the general design of the machine, he recognized some details of value in it, but these were embodied in the designs sent in by Mr. C. E. L. Brown, of Baden, perhaps the man who had done most towards high-pressure work and long-distance transmission. With regard to the cooling of the bearings, it was a very general practice amongst English and Continental engineers to circulate water continually in the jacket round the bearing, which of course was preferable to throwing water on from a hose according to marine practice, but in this case he should say it would be very effective if water were always left on. There should surely be enough water at Niagara to make this possible. He considered the exciting a large plant like that in series was anything but the best arrangement; he believed the old parallel method of exciting, had many points in its favor. The question of transforming up was in practice a very awkward one. It led to many objectionable results, and was especially bad where it was combined with other dynamos working direct on the circuit at high pressure. He believed it was contemplated to make those dynamos of higher pressure than 20,000 volts; then, he supposed, the old ones would have to be rewound, remodeled, or worked on this objectionable plan. There was, he thought, a very great difference, which might not appear at first sight, between designing dynamos and building them; in fact, a thing which one made one's ordinary daily business, was very different from getting together a collection of all the information which was available in the world, and, then, without any previous knowledge of dynamo design, and especially building, and more especially running, to design a machine which was hoped to fulfil great expectations. With regard to the next point, that of the construction of the line and the voltage to be used, as he understood it, it was proposed to use an electromotive force of 20,000 volts on the assumption that, as at Deptford, there had been used an electromotive force of 10,000 volts; 10,000 volts with one pole to earth, so the safety would be equally great with 20,000 volts, and both poles insulated. He thought this was a great fallacy. If they had two cables both insulated from earth and charged in this way, it was exceedingly unstable and dangerous. If they adopted the safest method of conveying electricity, namely, by concentric cables, then the outer conductor took the same potential as that of the earth. If the two cables were separate they were liable by any accident which might occur in practice to have one put to earth. Then they would have a reversal of strains, the whole theory of 20,000 volts being as easy as 10,000 being upset, and they would have conditions which they had not provided for. Taking this pressure of 20,000 volts, the question was how to insulate it. He read in the paper that a subway had been partly built to carry the cables. The first impression upon his mind, and also the last after carefully considering it, was that that subway would be a very hot place; 10,000 volts was quite alarming enough when it got out of control; 20,000 with big horse-power at the back would, he thought, be worse. He thought it was quite possible if any fault did occur in the subway it would cause a very serious state of affairs in the whole of that subway, or, at any rate, through a considerable portion of it, and it would probably lead to the complete breakdown of the system. Next they had the question of periodicity. He could not agree with the periodicity of 16⅔ per second, or even with a periodicity of 25. He was sure there must be a considerable amount of lighting to be done. Why should this lighting be sacrificed? Was there going to be a proportionate gain in the general working of the system by using such a low periodicity? He did not think there would be. He believed the system adopted by Ganz at Buda-Pesth was a more satisfactory one to work at, somewhere about 40. It certainly rendered both arc and incandescent lighting possible, and was somewhere about the happy medium. With regard to the higher periodicity which they had heard spoken of in connection with this Paper, there were enormous difficulties in working with it. It had been spoken of as though it really was not an important thing; but there were very serious effects. In the first place, the capacity effects were much worse where they had to deal with capacity at this high periodicity, and what was much worse than that again was the magnetic retardation due to the field excited round the conductors. This would be alluded to fully in a Paper shortly to be read, and he would not further touch upon it, except to say that it was a very grave difficulty. He ventured, however, to say that so high a periodicity as 100, or even 86, as at Deptford, would be fatal to an economical working of the system. They came now to a most interesting question—how was electricity to be transmitted to a very great distance, by what method was it going to be done? Was it going to be done by alternating currents or by continuous current? He must say he did not see the faintest chance of its being done with the continuous with the present knowledge; but, at the same time, he saw very grave difficulties in the way of doing it by alternating currents.

There was one side of the question which he thought was much more important to the Institution than the periodicity, or the electromotive force, or the design of the dynamo. It was the general principle upon which the Cataract Construction Company had obtained its information. They proceeded in an exceedingly clever way. They formed a Commission, asked the greatest scientists of the day to join them, got a room at the City and Guilds Institute at South Kensington, and gave the Commission power to offer prizes, very small ones, and used other means, in fact any means, by which they could draw and collect information. He had had the pleasure of meeting some of the people who had sent in specifications. He himself did not send any. Various schemes were sent in. There were those great scientists, men they would not think of questioning, to give the thing perfect legality, and everybody thought it was a good thing. The information was not sent in by amateurs, but by people who had to make their living by building dynamos or some such articles. One firm spent at least £1,000 in doing it, and they might take it that that money did not represent the whole cost nor the value of the brains of those able men who had been engaged in working out a scheme. Nothing sufficiently satisfactory having been obtained, what was the next step? The engineers of the company were sent round to the different works on the Continent to gain information, the Company knowing full well all the time that that information was not going to be used to the benefit of those who gave it, or be adequately recompensed. It was upon the information so obtained that the designs and schemes which had been put before the Institution had been got out; it was upon the work of the world, the electrical world, unrecompensed, that the undertaking would be carried out at Niagara. He did not blame Prof Forbes, but it had been beautifully worked out by the Company, and nearly everbody had fallen into the trap.

THE DESIGN OF SWITCH CONTACTS AND BREAKS.

I HAVE been searching for some time past for rules for the design of switch contacts and breaks to suit various currents but have found no articles as yet on this subject. Can any of your readers give me any information or references on this subject?

V.

THE THEORY AND DESIGN OF THE CLOSED COIL CONSTANT CURRENT DYNAMO.—II.

BY PROF. HENRY S. CARHART.

THREE METHODS OF GOVERNING.

Assuming still practically constant speed, we next inquire into the methods employed to maintain a constant current without appreciable sparking by rocking the brushes round the commutator cylinder.

In one machine the brushes are moved automatically by means of a small electric motor and at the same time field coils are successively cut out as the brushes rock forward with a light load. A pair of brushes is used on each side and they are kept at a fixed distance apart. By these combined means the machine can be run on short-circuit with normal current and without sparking.

Another system leaves the field coils constantly in circuit but employs two pairs of brushes and varies the angular distance between the members of each pair when the brushes are moved. The movement of the brushes is effected mechanically in response to any change in the main current till the current is brought back to the normal value. In these machines the spread of each pair of brushes, or what is sometimes called the overlap of the brushes, is lessened as they rock forward toward the polar centres. Very satisfactory results are secured in this way.

In the third class of machines only one pair of brushes is used which lap over about two or three commutator sections and the regulation of the current is effected solely by the movement of this one pair without change of overlap and without disturbance of the ampere turns on the field. The brushes are moved mechanically by means of an automatic regulating device. No less satisfactory results appear to be secured by this method than by the others, while the mechanism as a whole is somewhat simpler.

I have described these three methods for the purpose of pointing out their bearing on the theory and design of closed-coil Gramme rings for constant currents. The important question is not how to get the necessary E. M. F. with such a dynamo, but how to vary the E. M. F. in response to the varying demands of the external circuit, without injurious sparking at the brushes.

The E. M. F. is controlled in all three of these methods by rocking the brushes, and the other differences in the devices are made necessary for the supression of the sparking. This brings us to a consideration of the most intrinsically interesting topic of the paper, viz., the conditions necessary to suppress sparking and the features of design required to furnish them.

SUPRESSION OF SPARKING.

If we assume that the armature is well balanced electrically and magnetically and that the brushes have a proper bearing in contact with the smooth commutator, the conditions required to commute the current without sparking are known to be as follows: With a two pole dynamo, the current is divided through the armature, one half going from brush to brush through one side and the other half through the other side. Hence when an armature coil is carried past the brush it is transferred from the one circuit throughout the armature to the other, and at the same time the current through it reverses its direction. This constitutes the act of commutation. But the sudden decay of a current through a coil in one direction and its growth to an equal value in the other gives rise to an E. M. F. of self-induction opposing the change. This E. M. F. will prolong the flow of the current on one side of the brush and will oppose it rise on the other side. Hence if the coil is short-circuited by the brush lapping over the two consecutive commutator segments to which its ends are connected, even when the coil passes the neutral plane of the dynamo, the E. M. F. of self-induction produces a local current through this coil; and when the one end of the coil slips past the brush and becomes a part of the other half of the divided circuit the current which should reverse through it meets the opposing current and breaks over the gap to the brush with a spark. Hence the commutation must not take place at the neutral plane but in advance of it, and in a field where the induced E. M. F. in the coil shall be just sufficient to offset the self-induction, and in addition reverse the current in the coil while it is passing through the brush or pair of brushes, and cause it to grow to the normal value at the instant when one end of it passes out from under the brush. The induction from the field must be sufficient to bring the one current to zero and to set an opposite one of equal value flowing in the coil, during the time it is under the brush. Then the commutation will be sparkless.

Now if the current is kept constant in strength the field induction required to accomplish the results described is approximately the same, whether the coil is short-circuited at one angle or another in advance of the neutral plane. It would appear at first thought that, unless the induction in every part of the field from the neutral plane to a point nearly 90 degrees in advance of it is substantially uniform, terrific sparking must result when the brushes are shifted far forward to vary the electric pressure to suit the requirements of the circuit; for, if the induction is in excess of the requirements to accomplish the result described in the commuted coil, then the current will circulate through it during the short-circuit, and the rupture of this on leaving the brush will cause sparking. I have illustrated this action in the following manner: Separately excite the field magnets of a machine, which can run on short-circuit even, with a forward displacement of the brushes without sparking. Then, leaving the armature on open circuit, rock the brushes forward; the sparking will increase with each advance till it becomes terrific and endangers the machine. The induction to which each coil is subjected in an excited field produces a large current in it while it is under the brush, since there is less self-induction in the coil to offset the induction from the field than there is when the machine is self-excited and working in the normal way. There is another reason to be described later.

Considerations of this kind have lead some writers to say that sparkless commutation for any position of the brushes can be accomplished only when the induction in the field is made uniform. The Statter constant current machine in England is made on this principle. Portions of the pole pieces are laboriously cut away at such points as to make the density of the lines of force entering the armature over a given angle equal. Of course a machine built in this way will permit of shifting the brushes through a considerable angle in order to vary the potential difference without introducing sparking, but while a uniform field accomplishes the result, no such uniformity is required; the same result may be secured in other ways. The first method already described weakens the field when the brushes move forward by cutting out ampere-turns in the field magnet. This reduces the induction to the proper amount at each point without changing the overlap of the brushes. It is made necessary by the very high saturation of the armature core in this machine. It has the advantage of greater economy with small loads because field resistance is cut out, but it requires a more complex arrangement of parts on the machine than suffices for the mere movement of the brushes.

THE NORTHWESTERN ELECTRICAL ASSOCIATION.

The annual meeting of the Northwestern Electrical Association was held at the Hotel Pfister, Milwaukee, on January 17, 18 and 19, as noted in our columns last week.

At the evening session Mr. W. N. Stewart, of the Siemens & Halske Electric Company, read a paper on the "Advantage of Direct Connection," describing his idea of a model central station, his plans being based on the methods employed in several European cities.[1]

Prof. D. C. Jackson of the Wisconsin University, read an interesting paper on "Essential Station Instruments"[1] that is worthy of careful perusal.

On Thursday President Paige called the members to order at 10 o'clock, and a ballot was taken resulting in the selection of St. Paul as the city in which the semi-annual meeting would be held on the third Wednesday in July. Of the 27 members voting, 20 favored the city named.

Mr. Will W. Low, president of the Electrical Appliance Company, Chicago, then read a paper on "The New Things in Electricity," holding that from the central station-man's point of view the very complete catalogues and discount sheets, together with the salesmen possessing consciences, are the best among the new things in the supply business. Mr. Low then briefly referred to the inherent excellent qualities to be found in an insulated wire, a new transformer, an alternating arc lamp, and an incandescent lamp which his company is handling, and of the merits of which natural modesty forbade him saying more. As all but one of the supply-men present,—a gloomy individual answering to the name of Bunce,—claimed to have a conscience, the paper was not discussed.

Mr. W. Forman Collins followed with a thoughtfully prepared paper on the "Economical use of Transformers,"[2] dealing more especially with the theoretical side of the question, and maintaining that the highest economy is secured when the transformers are large and few in number.

Mr. Parmelee J. Mc Fadden, of the staff of the General Electric Company followed with some interesting practical details,[1] so clearly and concisely presented that little was left for discussion.

Following the opening of the discussion, **Mr. John Schuette**, the well-known banker of Manitiwoc, related his experience in dealing with the question of transformation of currents, and his remarks were listened to with interest. He believed that the only point to consider was how to get the best results from the equipment now comprised in their plants. **Mr. E. L. Debell**, of Sheboygan, believed that for business houses where the load seldom varied, the individual transformer is the more economical, but for residences the best results are secured by using large units. The European practice of employing a bank of transformers was referred to; a suggestion made that inventors be asked to produce a practical device that would automatically cut out a single transformer when not in service, and prevent the loss following the employment of many transformers after midnight. Then the relative merits of the five-wire direct current system *versus* transformers were discussed. **Mr. W. N. Stewart** was in favor of the method comparatively new in this country but which the Siemens-Halske Company, employ in several of its European stations. Mr. Stewart maintained that there was scarcely a town represented in this association standing in need of a transformer system, that the price of copper was no longer the bugbear to be dreaded, and that the limited area covered by the present circuits would, in many cases, render it a profitable investment were the present systems displaced by the five-wire. Mr. Stewart asked the very pertinent question why the General Electric Company had not brought out and developed the merits of the five-wire system they owned and which was an extension of the three-wire system: "Five wires," he said, "can be installed more cheaply than transformers." Then followed a ploughing up of the old danger field, and many hypothetical cases of death following the handling of lamp sockets on alternating current circuits, were referred to. **Mr. Forman Collins** and **Mr. McFadden** explained how almost impossible was the likelihood of the primary current passing in on the secondary mains, as the secondary coil would burn out if the secondary fuse did not blow, which it had always been known to do. **Mr. George Mayo** thought that if there was the slightest danger to life from handling lamp sockets on alternating circuits it certainly would have been manifested long ago, for there were several hundred thousand such lamps in service. Mr. Debell referred to an accident resulting in a severe shock and burn, but admitted that the transformer was not of an improved type, but had a wooden base on which moisture often collected. Mr. McFadden explained the facts of a case wherein a defective socket and a grounding of the primary current caused serious trouble, but admitted that it was a very rare occurrence. **Mr. W. H. Thorpe** suggested methods for overcoming some of the difficulties mentioned. **Mr. Thomas Grier** stated that it was his practice to install transformers on a basis of an overload of 33⅓ per cent. and that this method had proved satisfactory. **Mr. P. H. Korst** referred concisely to the practice in several stations, and **Prof. D. C. Jackson** stated that some of the troubles referred to might have been prevented had attention been paid to well-known laws of engineering, the transgression of which always reacts unpleasantly on both pocket and physical comfort; that, usually, the better plan to follow when contemplating changes would be to call in engineering talent in each special branch of electrical work. These remarks were heartily endorsed.

At 2.30 P. M. the members again assembled and remained in session until 6 P. M. Following the call to order Mr. E. L. **Debell** of Sheboygan, read an interesting paper on "Corliss compound engines for Electric Light Work."[1]

Mr. H. C. Thom, of Madison, then stated that he had intended to prepare a paper on the subject "How Shall Members buy Supplies," but, with the permission of the president he would read two letters he had received and then follow with a paper entitled "The Trend of Electrical Investment."[1]

Hardly had Mr. Thom ceased speaking when a discussion began that lasted for two hours. **Mr. W. F. Collins** believed that the real blame for having non-paying plants rests on the men who endeavored to save the cost of the services of a competent consulting engineer, and that in some cases it might prove profitable to employ an experienced electrical engineer to overhaul the entire plant and place it on a paying basis. **Mr. Norcross** believed that only business principles should prevail in this, the crowning industry of the future; then there would be no non-paying lighting plants. **Mr. Stewart** referred to the fallacy of cutting rates. **Senator Merrill** referred to the lack of knowledge regarding the cost of a horse-power hour; **Prof. Jackson** suggested the wisdom of first determining what the current costs at the dynamo or the switch board. Then the discussion drifted off into the keeping of station accounts and the proper rate to charge for arc and for incandescent lighting, and on motion, Prof. Jackson was requested to prepare a paper "On the Best Methods of Keeping Central Station Accounts." This Prof. Jackson promised to do provided the members would send to him copies of the forms now used and such data as would assist in the preparation of the paper.[3]

Mr. John Schuette made an observation to the effect that his superintendent files a daily report, and at the end of each six months Mr. Schuette declares the dividends and divides the surplus profits among the stockholders. The appointment of a committee to recommend a schedule of prices for arc and incandescent lights was discussed and on motion carried.

The following committees were then announced, several new members added, the business closed up, and an adjournment carried.

Committee on Legislation.—H. C. Thom, Geo. Merrill, George Grimm.

Committee on Transporation.—I. P. Lord, Pliny Norcross, O. M. Race.

Committee on Entertainment.—J. C. Woodward, W. B. Baker, L. E. Debell.

Committee on Special Legislation for Underwriter's Rules.—H. C. Thom, Pliny Norcross, J. A. Andrews.

---

[1] An abstract of this Paper will appear in our columns.—Eds. E. E.

[2] See page 97.

[3] It will materially add to the value of Prof. Jackson's paper if every central station manager who may read this summary of the proceedings, will send a set of forms and any suggestions that would aid in formulating a standard system to Prof. D. C. Jackson, Madison, Wis.

Committee for Preparing Rate Schedule.—Geo. A. Davis, George Farwell, P. H. Korst.

The members and their friends, to the number of nearly one hundred, attended the banquet at 8.30, and listened to the remarks of the admirable toast master, Mr. W. H. Thom and several other witty speakers.

There was also some excellent music, after which Mr. Thom made a few appropriate closing remarks, and the members adjourned to the Clubroom where they passed the next two or three hours in making the night merry.

On Friday the members and their friends were the guests of the local committees and visited the new and model shops of the Milwaukee Street Railway Company, the power house of the E. P. Allis Company, the Pabst Brewing Company, the Edison, the Siemens & Halske and the Badger local stations.

From the beginning it was a very enjoyable affair and everyone—especially the supply men—were tireless in their endeavors to promote the best interests of all; and the bonds of good fellowship were closely united among the different interests represented.

ECONOMIC USE OF TRANSFORMERS.[1]

BY W. FORMAN COLLINS.

In the distribution of electrical energy by means of alternating currents the transformer may be considered to be the key to the situation, because by its use we are enabled to so change the form of the energy as regards its electromotive force and current as to render it suitable for the operation of all kinds of translating devices and transmit it from point to point cheaply and with small loss, and it accomplishes all this for us without any rotating or moving parts, which is its most important feature of value. By considering the several features of transformers and studying the way in which they operate we can arrive at the right way to secure the greatest economy in their use. Perhaps the best way to do this is to look at the problem as follows: The actions that go on in a transformer, the losses that occur, the methods of construction and distribution.

Actions. A transformer is, to all intents and purposes, similar to a dynamo which has no rotating armature but in which, instead, the magnetic lines of force are caused to alternate rapidly by connection with a source of alternating current; an electromotive force is produced in the primary coil by the alternating source varying the magnetic lines that link through the coil; these in turn pass through the secondary coil which is in inductive relation to the primary and produces an electromotive force in it also, because the two coils are connected magnetically by being wound about the same iron core. The rate at which the magnetic lines due to the primary current are cut by the secondary coil represent a measure of the electromotive force given to the secondary. The voltage produced at the terminals of the secondary coil depends simply upon the ratio of the number of turns of the wire in each coil provided the induction is the same through both.

A transformer on an alternating circuit possesses inherently a property of inductive resistance or impedance which is similar in its action and effects to the back electromotive force of an ordinary motor which only allows the absorption of a very small current when there is no work being done by the motor, this small current being sufficient to rotate the armature and overcome the frictional and other losses. The inductive resistance of the primary acts in the same way, opposing the pressure on it and almost balancing it in a well designed transformer so that but a small current is absorbed in the primary when there is no work being done by the secondary in supplying lamps or other apparatus.

Losses. There are several sources of loss in a transformer which may be divided into two classes; magnetic losses, or those which take place in the iron, and conductor losses, or those which take place in the copper coils. The former comprise magnetic leakage, the loss by hysteresis due to the rapid reversal of the magnetism, heating of the iron core and eddy currents; the latter, the drop or loss of voltage in overcoming the resistance of the copper conductors and the energy dissipated in heat which varies as the square of the current passing. Magnetic leakage is due to the fact that some of the magnetic lines of force leak out along the core instead of passing through the secondary; this leakage effect is increased by the opposing magnetic action of the secondary to that of the primary, and the direct result is a lowering of the electromotive force of the secondary. Even when there is no load on the secondary some magnetic leakage is taking place. When the transformer is running light the primary coil absorbs current enough to produce a field sufficiently strong to balance the voltage of the primary. The current thus absorbed is termed the "idle" current and it is of course necessary to have it very small.

The iron loss is dependent on the induction, and the amount and kind of iron used. It is generally conceded to be most advantageous to have the losses in the iron as small as possible, because they are continuous and are going on all the time irrespective of the conditions of the external circuit. On the other hand the copper losses are only maximum during the periods of full or very nearly full load, which is not the general condition of the transformers, although it should be; therefore it is unnecessary to have them unduly small; furthermore the element of cost enters quite markedly into this portion of the subject. When there is no load there is practically no loss in the conductors.

Construction. It is very important to have a well designed and carefully built transformer because the coal bill will be most wonderfully affected by the employment of wasteful and inefficient apparatus. Transformers are generally built with closed iron magnetic circuit to reduce leakage and keep down the primary magnetizing current. It may be well to mention here incidentally the "hedgehog" type of transformer due to Mr. James Swinburne which uses an open iron magnetic circuit of special form.

Care should be taken to have the resistance of the coils low to prevent drop of voltage and heating, and the leakage small. To carry out the latter condition the coils should be placed preferably one surrounding the other but should not be wound so that their turns interlace or are in alternate layers. The cores must be of finely divided iron, the laminations insulated from one another to reduce eddy current and prevent heating; stampings are generally used because the manufacturing cost is thus lowered. A low induction must be employed to prevent undue heating and the iron must not even at full load approach the saturation point.

A well made closed iron circuit transformer should give a high efficiency not only at full load but also at light load. For measuring alternating currents the various dynamometer instruments and the well known Cardew voltmeters are quite accurate for practical work; although probably the most exact way is to use the electrometer which, however, is not well adapted for ordinary work as it is exceedingly delicate and requires suitable conditions and considerable skill and care in handling.

Distribution. It is quite as necessary to arrange the transformers for any particular distribution so as to obtain the most economical performance at all times as to secure transformers of high efficiency in the first place. With the primary pressure constant, as the load on the station is increased the tendency of the secondary voltage is to drop on account of the leakage and the ohmic resistance of the coils. This must be compensated for at the station so as to maintain the pressure of the secondary circuits constant to ensure good service from the arc or incandescent lamps and motors that may be connected. A good transformer, however, supplied with constant electromotive force should give very nearly constant electromotive force on the secondary for all loads within its capacity. The usual condition of a lot of transformers run from a central station is that of light load and often for a great portion of the time without any load at all. It has been observed by all operating alternating plants that with a non-inductive resistance such as incandescent lamps the drop under varying load is smallest, being greater on arc lamps or motors because of the presence of self induction in the latter, and it is even possible to have an actual rise in pressure as was experienced on the long cables of the huge Ferranti station at Deptford, England, and ascribed to their capacity action.

For running arc lamps it is not desirable to have the periodicity too low; about 50 is generally used. The average loss in distribution by alternating currents is remarkably small, about 5 to 10 per cent. divided up about equally between the circuits and transformers. Loss of energy is proportional to the square of the current employed and the weight of copper required varies inversely as the square of the electromotive force, or in other words, one-fourth of the amount of copper is required to transmit any given amount of energy at twice the pressure.

It is evident that a small converter will not be nearly as efficient as a large one because the magnetic circuit cannot be as short, relatively speaking or the copper coils as compactly arranged, and it will heat far more; it is also plain that a small converter will cost more per lamp output than a larger one. From these two most vital considerations large transformers are both cheaper and more economical and less of them are necessary. They can be just as desirably used as a number of smaller ones, by taking a little care in laying out the circuits and distributing them so as to reach as many consumers as possible with a single large transformer and its attendant advantages. At first sight it might appear as if the increased amount of copper used in the larger secondary mains would be injudicious but this is not so (provided, of course, discretion is used) because the slight additional cost of conductors is completely overbalanced by the diminution of losses in the transformers which are permanent and continuous. The regulation of large transformers is also superior; they are much lighter for their output and cost less to install. The difference in efficiency is quite marked between a 10-light converter and a 100-light one; for instance, while the former will probably have a full load efficiency of 88 per cent. or 90 per cent. the latter will be as high as 95 per cent. to 97 per cent.

Summing up the conclusions arrived at, it is apparent that to fulfill the requirements of most economical operation, transformers of the highest all round efficiency under varying load should be used and so far as circumstances permit, let them be large in size and few in number.

---

[1] Abstract of a paper read before Northwestern Electrical Association, Milwaukee, Wis., Jan. 17-19, 1893.

SOME DATA ON THE COST OF TELEPHONE WORK IN NEW YORK CITY.

The Metropolitan Telephone and Telegraph Company furnish the following interesting information with regard to certain features of their New York Telephone System and the Broad Street Exchange, recently illustrated and described in our pages:—

The Broad Street Exchange, which serves the district bounded by Wall Street and Broadway from Wall Street to the Battery, is the eighth central office of the New York telephone system. It is one of the four larger offices which have been placed in fire proof buildings specially constructed to contain telephone centres. In every feature it represents the most modern development of telephone engineering, and so rapid has this development been, that in no single item of its equipment does the Broad Street Exchange resemble the equipment of a telephone exchange of four years ago.

As an illustration of the continual reconstruction of a large telephone plant that is rendered necessary by the constant improvements in apparatus and methods, produced in response to the continual demand of the public for increased telephone facilities and for perfect service, the Eighteenth Street Exchange is a case in point. This exchange was recently moved to a new building, and to effect the removal an entirely new central office equipment was constructed, and the equipment of the old office, which had been in service a *few days more than four years*, was abandoned and the greater part of it was sold as junk.

The Broad Street Exchange at present supplies telephone service to some 1,100 subscribers, all of whom have been transferred from the Cortlandt street office, which, until lately, served nearly 5,000 subscribers and was overcrowded. The ultimate capacity of the Broad street office is for 3,000 subscribers. It contains the latest type of metallic circuit multiple switchboard, a notable feature of which are the ingenious self-restoring indicators. These indicators return to their normal position automatically, thus relieving the operator of two manual operations, and consequently quickening the service.

During the past year or two, improved methods of construction of lines and the placing of underground cables have been pushed with great vigor, resulting in the removal of old overhead wires and their substitution by copper metallic circuits throughout. In the Broad street district few old style lines now exist, and not a single wire enters the exchange overhead. All the subscribers' lines are brought into the building through the basement in lead covered cables, each containing fifty metallic circuit conductors. At the ends of the cables the conductors are connected to lightning arresters, which prevent dangerous currents from reaching the switchboard apparatus. The conductors next pass through a special switchboard or connecting rack where they make their union with the wires of the operating switchboard proper. This connecting rack is designed to allow of the junctions between the subscribers' lines and the switchboard being interchanged whenever necessary, and gives great flexibility in the apparently complicated system of wires.

Special features of interest are the generating plant, where current is produced for charging the switchboard transmitters and for ringing the subscribers' bells: the desk of the "wire chief," provided with apparatus for testing the subscribers' lines and locating "troubles;" the desks of the monitor and exchange manager, which are equipped with lines running to all parts of the switchboard to enable proper supervision of the operation to be maintained.

The telephone system of New York City consists at present of eight exchanges, equipped with metallic circuit multiple switchboards, having a total accommodation for 15,000 subscribers, upwards of 9,600 subscribers' stations, 800 private line stations, and 80,000 miles of underground wire. The entire system is constructed on a basis of exclusive metallic circuit working. About sixty per cent. of the subscribers now have metallic circuit lines and equipment, and the conversion from the old style grounded lines to metallic circuits is progressing with great rapidity.

With a metallic circuit line and office equipment, a New York telephone subscriber can talk from his own desk to any one of upwards of 100,000 telephone subscribers in other cities, some of them over a thousand miles distant. This extraordinary development of telephony in America is in striking contrast with the state of the art in Europe, where subscribers can get only local service from their own instruments, and, to use a long distance line, must go to the terminus of the line, making an appointment with the distant correspondent first by telegraph.

There are between 80,000 and 90,000 conversations by telephone each day in New York City, and the average use of the telephone by each subscriber is 16 times daily. Many busy subscribers use their telephones from 100 to 200 times daily.

For the entire system there are over 400 lady operators. About 250 are on duty at the switchboards at the same time. The average number of connections made daily by each operator is a trifle under 400. At every exchange, comfortable sitting rooms, provided with lockers, tea and coffee urns, etc., are established for the use of the operators when not on duty at the switchboard.

A peculiar feature of the daily business of a telephone exchange is its enormous fluctuation. Although the service is permanent, the greater proportion of the twenty-four hours' work is compressed into two periods of about two hours each. In order to cope with these high pressure periods without delay in the service, the entire plant and personnel of the system have to be organized as if the whole of the day's work were on the same plane. Besides the operators, there is at each exchange a skilled force of electric wiremen constantly engaged in making connections and keeping all parts of the plant in efficient working order. None but skilled labor is employed in any part of the telephone system.

The working force needed to maintain the telephone service consists of about 1,000 persons, an average of one employee to every nine subscribers. The technical work is carried on by departments, each having a large force of men under a responsible head. Some idea of the amount of construction work done can be gained from the fact that during 1893 more than 8,000 lines were built and an equal number of stations equipped and more than 2,000 disconnected and removed.

SOCIETY AND CLUB NOTES.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Mr. C. O. Baker, Jr., Master of Transportation, issues the following notice:—

"The Boston Passenger Committee and the Southern Passenger Association have granted a rate of a fare and a third for the round trip from points in their respective territories to members and delegates attending the Washington Convention."

Secretary George F. Porter has sent out his preliminary circular of invitation to central station companies to attend the Washington convention. Its programme includes the following special "Topics of Discussion":—

What is the most economical Size for Arc Dynamos; Arc Lights on Incandescent Circuits; How to Rate Arc Lamps; Underground Circuits; How to Wire Buildings; Commercial Alternating Motors; Electrolytic Effects of Return Currents; Motors vs. Flat Rates; Storage Batteries.

A paper entitled "Electric Lighting at the World's Fair and Some of its Lessons," illustrated with stereopticon, by T. C. Martin and L. Stieringer; "Impressions of a Central Station Man Abroad," by E. A. Leslie; "The Importance of Complete Metallic Circuits for Electric Railways," by J. H. Vail; and other papers, subjects to be announced, are promised.

DR. BELL'S LECTURE IN THE ELECTRICAL WORKERS' COURSE.

The second lecture in the University Extension course of the Electrical Workers was delivered at Cooper Union by Dr. Louis Bell, who addressed himself to the subject of "Alternating Current Dynamos and Motors." The lecture was a beautifully simple, clear and compact treatment of the alternating current and of the apparatus by means of which it is generated and utilized, and the descriptions given carried the audience by easy, evolutional stages from the rudimentary methods of the past up to the more involved transformations of the present, and the new polyphase work on which so much depends. Dr. Bell illustrated his remarks with numerous large diagrams on the black board, and had a stageful of apparatus by way of ocular demonstration. The audience was very attentive and appreciative, and it is worthy of comment that it numbered considerably over 600—a striking testimony to the value of these popular addresses on scientific topics.

HARVARD ELECTRIC CLUB.

Mr. Thomas D. Lockwood, of the American Bell Telephone Co., gave an interesting lecture, Wednesday evening, Jan. 17, on "The Progressive Evolution of the Telephone System of To-day." The history and growth of the telephone was traced from the time of the Centennial up to the present, thus showing the gradual advances and additions that have combined to make the practical telephone of to-day. The address was illustrated by telephonic apparatus and diagrams showing the various stages of development. Several members of the Bell Telephone Company and of the American Institute of Electrical Engineers attended the lecture.

Mr. Marsden J. Perry, of Providence, the banker and electric light magnate, has been appointed a joint permanent receiver with Thomas C. Platt, of the New York and New England Railroad. The appointment gives great satisfaction in Rhode Island and Massachusetts.

LEGAL NOTES.

INCANDESCENT LAMP LITIGATION.

THE INJUNCTION AGAINST THE BUCKEYE COMPANY DISSOLVED.—EDISON ELECTRIC LIGHT CO. VS. BUCKEYE ELECTRIC CO.

On Tuesday, January 23, Judge Ricks, Circuit Court of the United States, Northern District of Ohio, Eastern Division, granted the motion of the Buckeye Electric Company to dissolve the injunction allowed against them July 28, 1893, in the suit of The Edison Electric Light Co. for infringement of the Edison lamp patent.

The opinion of the Court, given in full below, is preceded by an elaborate statement of the case, the main points of which were stated in THE ELECTRICAL ENGINEER, of December 20, 1893, and which may be summarized as follows:

The contention was entirely upon the legal effect, as between the parties to the suit, of the now famous certificate of correction attached by the Patent Office to the Edison patent, upon the petition of Thomas A. Edison [The Edison Electric Light Co.] of November 15, 1883; reciting certain foreign patents for the same invention and requesting that the Edison patent of January 29, 1880, be so limited as to expire with the foreign patent having the shortest time to run. Among the foreign patents named was the English patent of November 10, 1879. It was contended in support of the motion to dissolve the injunction that by the procurement of such certificate Edison and The Edison Electric Light Co. were estopped from the enforcement of their patent after November 10, 1893, the period of the English patent being fourteen years. The Buckeye Company alleged that taking the corrected Letters Patent of Edison in good faith they had largely increased their investment in the business of lamp manufacture, having no reason to doubt the expiration of the Edison patent November 10, 1893.

The Edison Co. alleged that they had committed an error in procuring the correction of the patent in 1883—that in March, 1893, they had procured the cancellation of said correction—and that the correction, during the ten years of its existence as an endorsement on the patent, was in law null and void as limiting the period of the patent.

The points of contention on both sides are so clearly set forth in the text of the opinion of Judge Ricks, that no further preliminary statement is required here.

OPINION OF THE COURT.

RICKS, J.:

It will be seen from the foregoing statement of facts that the complainants do not deny the proceedings instituted by them in November, 1883, in the Patent Office, substantially as set forth in the defendant's motion. But they contend that they are not bound by the action of the Patent Office, taken upon their petition, for several reasons; among these, and chiefly:

FIRST. Because the petition for a limitation upon the duration of their patent, filed by the complainants, and the proceedings in support thereof on their part, were taken under a mistake as to the law and as to their rights under the patent, and that this error was corrected as soon as possible after discovery.

SECOND. Because the action and orders of the Patent Office were without authority of law, of no force and validity, and, therefore, did not in any way affect the patent.

The complainants' statement of the facts under which this action of the Patent Office was invoked, admits that they were advised and believed at the time that such action was necessary in order to remove doubts as to the validity of the patent as originally issued. These doubts arose because of a decision of one or more of the Federal Courts that it was essential to the validity of a patent, where foreign patents for the same invention had been applied for, that the date of such foreign patents and their limitation should be cited in the application, so that the limitation of the American patent would appear on its face. In view of the uncertainties thus existing as to the validity of the Edison patent, because of these omissions in the application for the patent, and, to remove all doubts, the patentee and the assignee both joined in a petition to the Commissioner of Patents, in which they stated that, while the application for Letters Patent No. 223,898 was pending, said patentee applied for and obtained letters patent for the same invention in several foreign countries as hereinbefore fully set forth in the statement of the case. The petitioners further represented that, because of the omissions of such recitals in the application, the United States Letters Patent were granted to the patentee, unlimited, for the full term of seventeen years. The petitioners further say that they were advised that said letters patent, when issued, should have been limited upon their face to the term of the foreign patent having the shortest term prior to the date of the United States Patent. Thereupon, the petitioners tendered the said United States Letters Patent to the Commissioner of Patents, and requested that they be corrected according to the provisions of the first clause of rule 164. Upon this petition, the Commissioner issued the following certificate:

"DEPARTMENT OF THE INTERIOR,
"United States Patent Office,
"WASHINGTON, D. C., Dec. 18th, 1883.

"In compliance with the request of the party in interest, Letters Patent No. 223,898, granted January 27th, 1880, to Thomas A. Edison, of Menlo Park, New Jersey, for an improvement in electric lamps is hereby limited so as to expire at the same time with the patents of the following named having the shortest time to run, viz.:

"British Patent, dated November 10th, 1879, No. 4,576.
"Canadian Patent, dated November 17th, 1879, No. 10,654.
"Belgian Patent, dated November 29th, 1879, No. 49,884.
"Italian Patent, dated December 6th, 1879; and
"French Patent, dated January 20th, 1880, No. 133,756.

"It is hereby certified that the proper entries and corrections have been made in the files and records of the Patent Office.

"This amendment is made that the United States Patent may conform to the provisions of Section 4887 of the Revised Statutes.

"BENJAMIN BUTTERWORTH,
[SEAL.] "Commissioner of Patents.
"Approved:
"M. L. JOSLYN,
"Acting Secretary of the Interior."

On the sixth day of March, 1893, the complainants, as petitioners, forwarded another application to the Commissioner of Patents, in which they recited their former petition, the action taken thereon; that subsequent thereto, by decision of the Circuit Court of Appeals of the Second Circuit, said former action of the Commissioner was declared to have been taken without authority of law, and therefore void, and asking that the former correction of the records by the Commissioner of Patents be canceled. Thereupon, the following action was taken by the Commissioner of Patents:

"Now, in compliance with the request of the parties in interest, said certificate is hereby canceled, and the proper entries and corrections have been made in the files and records of the Patent Office.

"In testimony whereof, I have hereunto set my hand, and caused the seal of the Patent Office to be affixed, this 15th day of March, 1893.

"W. E. SIMONDS,
[SEAL.] "Commissioner of Patents.
"Approved:
"CYRUS BUSSEY,
"Asst. Secretary of the Interior."

What is the legal effect of these applications of the petitioner and the action of the Commissioner of Patents thereon? It is urged on behalf of the defendant that these proceedings, deliberately taken by the complainants, amounted to a voluntary dedication by them to the public of the patent from and after November 10, 1893, at which time the British Patent expired by limitation. It is contended, in reply, that, even though such action was a dedication by the complainants as claimed, it was a dedication of something which was to be given to the public some time in the future, and, long before the dedication was to take effect, it was revoked and annulled, and no rights thereby passed either to the defendant or to the public.

Was this conduct and action of the complainants an abandonment of some right, or a dedication to the public of a privilege or right conferred. The arguments on this point have taken a wide range in the briefs of counsel. The action of the complainants in this case, while in the nature of a dedication to the public of a part of the time for which the sole enjoyment of the privileges of the patent were conferred, is not in all respects like the abandonment of a part of an invention by a failure to claim all of it, or by a disclaimer in express words of a part of it. In the latter case the right of the public to at once appropriate the abandoned or disclaimed part of the invention attaches, and the patentee is powerless to prevent such appropriation. In this case the complainants did not abandon or disclaim anything that could be immediately appropriated. It was a voluntary act by which they declared a limitation upon the duration of their patent, which shortened its term. It was not, however, as complainants contend, a simple declaration that, at the expiration of the shortest foreign patent recited in their petition for correction, they would then dedicate to the public the remainder of its full term of seventeen years conferred by the United States Patent. If its legal effect was such a dedication, to take effect ten years in the future, it would have been a gift or grant, which might have been subject to revocation. But the time for which the patentee is granted the sole enjoyment of the monopoly conferred is just as much the subject of a dedication and grant to the public as a part of the invention or process. The law on this subject is well stated in Robinson on Patents, Section 845, to be as follows:

"The patent privilege is not a mere reward bestowed upon the inventor for past services, the payment of a debt of gratitude toward one who has already conferred a benefit upon the state; it is also a purchase by the government, acting on behalf of the whole people, of some new art or instrument, capable of beneficial use, for which it recompenses the inventor by securing to him for a time its sole enjoyment; and when, without this recompense, it has obtained the invention through his voluntary act, so far from recognizing him as entitled to remuneration, it unhesitatingly appropriates his invention to itself, whatever loss and difficulty may result to him."

What, then, did the complainants intend to do, and what did they think they had the legal right to do, with reference to the legal difficulties which they believed then surrounded them? There can be no doubt as to what their intentions and purposes then were. They asked for the right to limit their United States Patent so that it might expire at the same time with the patent named having the shortest time to run. They named in their petition the British Patent No. 4576, and therein stated that the said patent was dated as of November 10th, 1879. They then believed that said patent would expire November 10th, 1893, for, if they correctly stated its date, it would by law then expire. The limitation thus deliberately put upon the duration of their own patent was then believed to be necessary to its validity. Acting under such a belief of their legal relations to the public, they then fixed the limit for their patent for what seemed to them a pressing necessity and a sufficient consideration. Whether the Patent Office was authorized by law or not to make such official correction, the petitioners unquestionably had the legal power to voluntarily fix a limit upon the duration of their own patent.

Did that power depend upon future revelations as to the correctness of the legal advice under which they acted? That their proceedings were taken under a mistake of law might give them the right to correct their error by proper application, made within proper time; but such misapprehension could not affect their power or authority to make such limitation of the grant conferred upon them.

But it is contended that their petition for correction was of such an indefinite character that it put the public and all parties interested upon their inquiry as to its legal effect. It is said that the duration of the patents set forth in the petition were not stated; and to ascertain such a limitation involved investigation as to the laws of the respective countries, and that if such investigation had taken place the defendant would have ascertained that the term of the British Patent did not begin until it was sealed and granted.

But the public, and those interested in the duration of the patent, had the right to accept complainants' statements as to the date of those foreign patents, and to act accordingly. In their petition for correction they aver that they were not advised that the practice of the Patent Office required an applicant to acknowledge during the pendency of his application a foreign patent applied for and granted subsequent to the filing of such application. The application for the Edison Patent was filed November 4th, 1879, and the patent was granted January 27th, 1880, so that by the admissions of their petition the British Patent was both applied for and granted between those dates, and expired between November 10th, 1893, and January 27th, 1894. The complainants cannot object because the defendant acted upon those representations. If complainants had taken no action whatever, but had relied upon their legal rights as they might be subsequently defined, the public would have acquired no advantages by the proceedings now under consideration. The defendant would have acted at its own peril, and have no claim such as they now assert. The complainants' conduct and public declaration of the facts concerning their patent are binding upon them, and they cannot now be heard to say that they were made in doubt as to their legal rights, and made in such uncertain terms as to put the defendant upon examination as to the facts and the law, and to be bound by its proper interpretation of them. Even conceding that said petition was filed under mistaken advice as to the law, and that it asked only for such action as the Patent Office might lawfully take, and that the terms in which said action was invoked were such as to put the defendant upon its inquiry as to the law, it was nevertheless a solemn and public act, by which it limited the duration of its own patent to a term shorter than that granted in the original patent. The petition and prayer was for such a limitation, and the complainants are bound by such declaration and conduct. Can there be any doubt as to their right and power to have made such a declaration and abandonment of an existing right? Such power is clearly recognized in Insurance Co. vs. Mowry, 96 U. S., 547.

But it is said this dedication was revoked. On the sixth of March, 1893, the complainants filed their petition in the Patent Office, as hereinbefore stated, and recited further that by the decision of the Circuit Court of Appeals for the Second Circuit said action of the Patent Office was declared to be "without jurisdiction and wholly void," and for these reasons asking that the records of the Patent Office "be amended so as to cancel the said statements and limitations, and so as to restore them to the same condition in which they were at the time of the original grant of said patent;" and further, "that the said certificate of correction attached to the said letters patent be canceled so that the patent will be in the same condition in which it was originally granted." Upon this petition, the Commissioner of Patents on March 15th, 1893, ordered: "That said certificate is hereby canceled, and the proper entries and corrections have been made in the files and records of the Patent Office."

By these proceedings it is claimed that if the petition for correction, and the proceedings thereunder of November, 1883, amounted to a dedication, such dedication was then revoked, and that the patent stands as though no correction had ever been taken or made.

It is further contended that the holding by the Circuit Court of Appeals for the Second Circuit that the action of the Commissioner on the first petition for correction was wholly void, and that the surrender of the letters patent for correction was without legal authority and of no effect, should be conclusive of this controversy. But this is not a controversy in which the authority of the complainants to surrender their letters patent to the Commissioner of Patents for correction, or his power to make such correction, and amend the records of his office, are involved. The defendant is not here asserting any such power, or claiming any such result as legal or valid. It is here, however, contending that, whether the Commissioner of Patents had legal authority for his action or not, the complainants certainly had the right and power to publicly and solemnly limit the duration of their own patent and make record of their intention to abandon it to the public from and after November 10, 1893, the expiration of their British Patent. Having done so, and the defendant having, in good faith, acted on said public declaration, it now contends that the complainants are estopped from coming into Court and asserting that such conduct was a mistake as to the law, and, therefore, not binding upon them. This involves the consideration of the question as to whether the complainants' conduct was a representation as to something it proposed to do in the future, and, therefore subject to revocation, or whether it was an abandonment of an existing right. I find the exact question, as it seems to me, fairly settled by the Supreme Court in the case of Insurance Company vs. Mowry, 96 U. S., 547. In that case the Court said:

"The only case in which a representation as to the future can be held to be an estoppel is where it relates to an intended abandonment of an existing right, and is made to influence others, and by which they have been induced to act. An estoppel cannot arise from a promise as to future action with respect to a right to be acquired upon an agreement not yet made. The doctrine of estoppel is applied with respect to representations of a party, to prevent their operating as a fraud upon one party who has been led to rely upon them. They would have that effect, if a party who, by his statements as to matters of fact, or as to his intended abandonment of existing rights, had designedly induced another to change his conduct or alter his conditions in reliance upon them, could be permitted to deny the truth of his statements, or enforce his rights against his declared intention of abandonment."

But in a later decision the same Court said it is not necessary that there should be a design or a purpose to mislead the opposite party on the part of the person to be estopped. In the case of the Leather Manufacturers' Bank vs. Morgan, 117 U. S., 108, the Supreme Court approvingly said:

"In Continental Bank vs. Bank of the Commonwealth, 50 N. Y., 575, it was held not to be always necessary to such an estoppel that there should be an intention upon the part of a person making a declaration, or doing an act to mislead the one who is induced to rely upon it. 'Indeed,' said FOLGER, J., 'it would limit the rule much within the reason of it if it were restricted to cases where there was an element of fraudulent purpose.' "

Many other cases are cited by counsel, pro and con, which it is not necessary to consider and review. The exact question we have under consideration seems to be met by the foregoing decisions, which are conclusive.

While it is true that the complainants' proceedings in the Patent Office were not had with any reference to the defendant, but had reference solely to their relations to the public, the defendant had, as one of the public, the same right to be influenced and governed by the complainants' conduct as though it had been the result of their representations to each other as individuals or corporations. The complainants' proceedings were a matter of public record. Their acts and conduct were of such notoriety that the defendant, by law, was bound to take notice of them, so far as they affected its legal rights under the complainants' patent.

But conceding that there is doubt as to whether the above decisions are conclusive of the controversy, the revocation which the complainants claim to have made of their dedication to the public was not made until March, 1893, nearly ten years after their voluntary limitation of the term of their patent, as hereinbefore stated. If they were in doubt as to the legality of their conduct in the proceedings in the Patent Office, they should have acted as soon as such mistake was suggested. They could not wait until the public had acted on their dedication, had acquired rights and equities, and then, after the Courts had declared their action unauthorized, proceed to revoke their grant.

Did the defendant, in good faith, act upon the complainants' limitation of the life of their patent, and was it induced so to act by the conduct of the complainants, and is it now in such relation to the complainants as estops them from denying that their conduct induced the defendant to make its investments and act as it has set forth in its motion now under consideration?

The circumstances under which the defendant began its enterprise of manufacturing electric incandescent lamps, the different stages in the progress of its development, and the reasons inducing it to increase its capital, are fully set forth in its motion, and as hereinbefore recited. Whatever may be the complainants' claim with reference to the defendant's statement of the circumstances under which it originally entered into this enterprise, it seems well established by the affidavits of the defendant's directors that its capital stock was increased, and its capacity for manufacturing incandescent lamps greatly enlarged by reason of its belief that the complainants' patent, by its own conduct, was limited so as to expire on the tenth of November, 1893.

This was a very important fact, and the claim that it largely influenced the defendant in its conduct is both reasonable and natural. For the reasons hereinbefore fully considered, it seems to me plain that the complainant is estopped from now claiming that its conduct did not induce such well defined belief as to the limitation of its patent on the defendant's part. Without deciding how far others not similarly situated had the right to rely upon such conduct on the part of the complainants, or without passing upon the question of how far the public generally acquired rights under the complainants' proceedings in the Patent Office, by which they limited the life of their patent, it is sufficient to find, under this motion, that the defendant, by reason of the circumstances particularly set forth in its motion, did rely in good faith upon the complainants' conduct, and had a right to be, and was, in fact, influenced thereby.

The application for a dissolution of the injunction is based upon evidence as to a fact which did not exist at the time the temporary injunction was allowed. At the time such application was made the complainants' patent had not then expired according to the limitation put upon it by its proceedings in the Patent Office. The rule is well settled that on such an application the complainants' rights to an injunction must be clearly established. While it is true that on a motion to dissolve, the burden of proof is on the defendant, yet the rule is equally well settled that evidence which would prevent the allowance of an injunction would be sufficient to dissolve it, and that an injunction will be dissolved on new evidence raising grave doubts as to the complainants' right to the temporary injunction in force. The rule is well expressed by Judge Nixon in the case of Carey *et al.* vs. Domestic Spring Bed Company *et al.*, 26 Fed. Rep., 138. In that case the complainants' patent, for the protection of which a temporary injunction was asked, had been sustained by three different Circuit Courts prior to the filing of the bill in Judge Nixon's district. Upon the strength of those prior adjudications, Judge Nixon ordered the injunction, "without an examination of the merits, or expressing anything upon the validity of the patent." But upon motion to dissolve, new affidavits were offered to show prior use. After an examination of these affidavits, Judge Nixon says:

"It does not appear that such testimony of prior discovery, knowledge and use of the invention was brought to the notice of either of the learned Judges who granted the injunction in the other cases. * * * I do not think that I should have seen my way clear to allow the preliminary injunctions in the present case if it had been presented on the original motion; and the rule is a good one that the evidence which would prevent the issuing of an injunction ought to be regarded as sufficient to dissolve one already granted."

For the reasons hereinbefore stated, if, on the application for the injunction now in force, the facts now relied upon in support of the motion to dissolve had been available as a defense, I would not have allowed the temporary injunction. The complainants' right to such an injunction, under such a defense, would have been so doubtful that it would not have been entitled to an injunction under the rules cited.

To continue the injunction now, in view of these doubts, would certainly be a great hardship upon the defendant. According to the affidavits now before the Court, the defendant is a solvent corporation. Under the Ohio law, the personal liability of the stockholders is an additional indemnity to which the complainants may look in case, upon a final hearing, its right to a permanent injunction should be established.

As the case is now presented on the motion to dissolve, the two parties must suffer loss. If the injunction is continued the defendant is wholly without remedy. It has shown that it was honestly misled by complainants' conduct, and, in good faith, made additional investments upon the belief so formed. The complainants cannot complain if, for this reason, the benefit of the doubts expressed are given to the defendant and the injunction is dissolved. If I am in error as to this conclusion, no great harm can result to the complainants, for if such error is established they can recover for the damages caused thereby, and their right to contest as to other infringers not able to show such meritorious claims to estoppel as defendant has established, can be asserted without prejudice from this decision.

STEPS IN THE EDISON-BERNARD LITIGATION.—PARTIAL INJUNCTION GRANTED.

In the suit of the Edison Electric Light Company against the E. G. Bernard Company, of Troy, N. Y., in the United States Circuit Court, the motion for preliminary injunction to restrain the defendants from erecting an electrical power and lighting plant at the Watervliet arsenal, has been denied by Judge Coxe as to the power plant, but the defendants are enjoined from using the feeder patent for lighting purposes until the determination of the suit. The text of the decision has been received as we go to press.

DECISION AGAINST A CITY PLANT AT HIAWATHA, KAN.

The decision of Judge Thompson on the electric light injunction case, wherein the city of Hiawatha undertook to put in an electric plant and compete with the private plant already there, was handed down on Jan. 20, and is against the city. The court holds that if the city could light the streets, it could also light the houses, which would be against franchise rights of the company.

LAMP LITIGATION IN PHILADELPHIA.

Argument was heard last week before Judge Acheson in the United States Circuit Court, Philadelphia, in the suit of the Edison Electric Light Company, to have the Manufacturers' Club, the Spreckels Sugar Refining Company and the Messrs. Crump, of the Colonnade Hotel, enjoined from using incandescent lamps alleged to contain infringements on the plaintiff's patents. A preliminary injunction was granted.

FEEDER AND MAIN PATENT LITIGATION.

Edison Electric Light Company *vs.* F. P. Little Electrical Construction and Supply Company, The Binghamton State Hospital, *et al.*

Edison Electric Light Company *vs.* E. G. Bernard Company, Isaac Arnold, Jr., *et al.*

United States Circuit Court, Northern District of New York.

Memorandum on Motions for Preliminary Injunctions.

Coxe, J.

My time is so completely occupied with other imperative matters that I cannot give to the consideration of these motions the examination which, in other circumstances, I would be glad to give them.

Regarding the action against the Little Construction Company and the Binghamton State Hospital, I think the contract should be considered in the light of the affidavits and explanations at the argument. To construe its language strictly in view of these subsequent statements would hardly be doing justice to the defendants. I am not sure, however, that I fully comprehend the details of the plant which the contractor proposes to install at Binghamton. So far as I am able to understand it I have considerable doubt whether the large conductor which is to be employed will infringe the patent in suit.

It is by no means clear that the contractor has adopted or will adopt the patentee's "particular way of forming such a conductor." It is difficult to comprehend the contractor's motive in using the very large feeder wires if the method in the patent is to be adopted. Though the Binghamton system is not the "Tree system," as the latter is described in the opinion in the New Jersey case, it would seem to be nearer the "Tree system" than the system of the patent. Surely there is a doubt.

When it is remembered that the speedy installation of this plant is necessary for the health and well-being of the unfortunate inmates of the institution I think the doubt should be resolved in favor of the defendants.

If the complainant deems a bond necessary for its protection it should be given. A bond in the sum of $5,000 is sufficient in the first instance. It can be increased should occasion arise.

As to the Watervliet Arsenal the case is different. It would seem that as to some, at least, of the consumption circuits, it is proposed to adopt the precise method of the patent. There can be no hardship to the United States in issuing an injunction, as the officers of the Government, by giving their approval to what, at the argument, seemed a perfectly fair and equitable arrangement between the complainant and the contracting defendant, can at any moment remove the only obstacle which prevents the speedy completion of the work. Having refused to grant this apparently reasonable consent they are not in a position to urge the inconvenience and injury to the Government as a reason for withholding the writ.

An injunction should issue, but it should restrain the defendants only so far as the electric lighting plant is concerned.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 9, 1894

Accumulators :—

Secondary Battery, F. K. Irving, New York, 512,473. Filed Sept. 13, 1893.

Claim 4 follows :

The gauze plate folded to form pockets, the porous cups within the pockets and the binding rods surrounding the gauze elements and porous cups to hold the elements in a group.

Electrode for Secondary Batteries, W. Morrison, Des Moines, Iowa, 512,514. Filed Apl. 25, 1892.

Consists of a plurality of bundles built up from a continuous ribbon of the requisite material and conducting rods connecting the bundles.

Alarms and Signals :—

American District Electric Signal Apparatus, C. E. Scribner, Chicago, Ill., 512,400. Filed Dec. 27, 1886.

Relates to apparatus in connection with district messenger service systems in which the call boxes in a certain district are electrically connected with the central station.

Fire Alarm Attachment, C. E. Egan, Chicago, Ill., 512,672. Filed May 27, 1893.

A push button normally used for ordinary signalling purposes but adapted to act as a thermostat in case of fire.

Conductors, Conduits and Insulators :—

Insulated Conductor, C. N. Waite, Newton, Mass, 512,417. Filed Feb. 20, 1893.

Relates to the insulation of lead gas conductors used in the manufacture of chlorine by the electrolysis of alkaline chlorides.

Distribution :—

Electrical Transformer or Converter, C. L. Coffin, Detroit, Mich., 512,603. Filed Dec. 11, 1891.

Claim :

In a transformer or converter a secondary formed of perforated metal.

Dynamos and Motors :—

Coil for Electromagnets, N. Tesla, New York, N. Y., 512,340. Filed July 7, 1893.

Claim 1 follows :—

A coil for electric apparatus the adjacent convolutions of which form parts of the circuit between which there exists a potential difference sufficient to secure in the coil a capacity capable of neutralizing its self-induction. See p. 87 this issue.

Spark Regulator for Dynamo Electric Machines, C. E. Scribner, Chicago, Ill., 512,397. Filed June 1, 1889.

Maintains the field of force of the short circuited coils practically constant while the field of force of the current producing coils is caused to vary automatically, responsively to variations in the resistance of the circuit.

Alternating Current Dynamo, J. J. Wood, Fort Wayne, Ind., 512,424. Filed June 23, 1893.

Relates chiefly to certain details of construction of alternating dynamos with stationary fields.

Connection between Separately Excited Dynamos and their Exciters, J. J. Wood, Fort Wayne, Ind., 512,425. Filed Oct. 17, 1893.

Employs a rigid connection between the movable bases of the dynamo and exciter so that the latter shall follow the movements of the former.

Device for Blowing out Sparks on Commutators of Dynamos, H. W. Hanahan, Winnsborougn, S. C., 512,612. Filed March 28, 1893.

Galvanic and Thermo-Electric Batteries :—

Depolarizer for Voltaic Cells, G. Hewitt, New York, 512,510. Filed April 3, 1893.

Consists of nitric acid, sulphuric acid and bichromate of sodium in the form of a dry powder.

Battery, W. M. Stine, Athens, Ohio, 512,567. Filed July 21, 1891.

Employs an alkaline electrolyte formed of a mixture of sodium hydrate, sodium zincate, sodium chloride, and sodium chlorate, the whole in aqueous solution.

Lamps and Appurtenances :—

Electric Incandescent Lamp, J. Peil and C. K. McFadden, Chicago, Ill., 512,320. Filed April 18, 1893.

Claim 1 follows :—

In electric incandescent lamps, the combination with a glass bulb of a metallic cap, a removable and insertible fusible metallic seal in the cap, and insulated inleading metallic wires inserted through the seal.

Lamps and Appurtenances :—

Duplex Arc Lamp, C. E. Scribner, Chicago, Ill., 512,401. Filed May 1, 1891.

Provides circuits and mechanism whereby two separate arc lamps connected in the same circuit may be caused to burn successively.

Socket for Incandescent Lamps, T. L. Pfarr, Jr., Pittsburgh, Pa., 512,448. Filed Feb. 13, 1893.

A socket and plug by means of which current may be taken to another point without disturbing the operation of the lamp or other device already attached to the socket.

Incandescent Lamp, A. C. Carey, Lake Pleasant, Mass., 512.461. Filed March 29, 1893.

Employs a bulb adapted to be fitted to ordinary sockets and to support a filament containing tube removable from it at pleasure.

Electric Arc Lamp, R. Niewerth, Berlin, Germany, 512,481. Filed March 22, 1893.

Employs a rotary shaft, a series of electrodes supported on the shaft, a commutator also supported on the shaft and a series of brushes bearing upon the commutator and connected with the source of electricity.

Electric Arc Lamp, R. Niewerth, Berlin, Germany, 512,482. Filed Oct. 24, 1893.

Claim 1 follows :

An electric arc lamp, composed of a series of electrodes arranged around a common axis and means for supplying the electrodes in pairs successively with electric currents in opposite direction, so as to impart alternately positive and negative polarities to the electrodes and form a continuous arc of uniform size.

Incandescent Electric Lamp, J. W. Turnbull, Pascagoula, Miss., 512,637. Filed May 2, 1893.

Claim 1 follows :

The combination with a bulb, of a separable tube, open at both ends, inserted therein and forming therewith a vacuum chamber.

Double Carbon Arc Lamp, C. E. Scribner, Chicago, Ill., 512,667. Filed April 16, 1892.

Metal Working :—

Furnace for Heating or Working Metals Electrically, C. L. Coffin, Detroit, Mich., 512,602. Filed Apl. 2, 1891.

Employs a refractory bed containing a coil of pipe the end of which opens through the bed, means for forcing air through the coil and mechanism for maintaining an arc on the bed over the end of the pipe.

Apparatus for Electrically Welding Metal, C. L. Coffin, Detroit, Mich, 512,604. Filed Mch. 9, 1883.

Employs means for maintaining two arcs, one on either side of the metal to be welded.

Metallurgical :—

Art of Producing Metallic Zinc, P. C. Choate, New York, 512,361. Filed Jan. 21, 1892.

Provides an electrolytic solution of zinc from which a commercially pure metallic zinc may be obtained by electrolysis.

Miscellaneous :—

Apparatus for Producing Ozone by Electricity, E. Andreoli, London, Eng., 512,265. Filed Aug. 25, 1892.

Electrolytic Apparatus, E. Andreoli, London, Eng., 512,266. Filed Feb. 20, 1893.

Employs supplementary cathodes of porous conducting diaphragms placed between the main cathode and the anode.

Stop Motion for Knitting Machines, G. J. Manderfield, Royersford, Pa., 512,310. Filed Mch. 21, 1893.

Electrically Propelled Vehicle, J. H. Rogers & W. Fracker, Washington, D. C., 512,327. Filed Jan. 31, 1893.

The application of a motor operated by storage battery to a light road wagon.

Time and Dating Stamp, W. S. Jewell, Indianapolis, Ind., and A. C. Stevens, Des Moines, Iowa, 512,378. Filed July 11, 1891.

Electric Valve Controller, C. E. Oagley, New York, 512,316. Filed Dec. 18, 1890.

An electric valve for regulating hydraulic elevators.

Electrolytic Diaphragm, T. Craney, Bay City, Mich., 512,505. Filed Sept. 26, 1892.

A tubular diaphragm consisting of an inverted U-shaped casing of non-porous material and containing a porous medium.

Railways and Appliances :—

Trolley Cut-Out, M. Hanford, Malden, Mass., 512,373. Filed Sept. 22, 1893.

The invention consists in making the trolley wire in independent sections electrically connected at the hangers and so supported therein that should a break occur the weight of the broken end will cause the end in the hanger to tilt upward out of connection with the line.

Closed Conduit Railway, C. J. Kintner, New York, 512,414. Filed June 22, 1893.

Employs normally disconnected sectional conductors and a series of removable pivoted switching boxes journaled in the sides of the conduit and mechanically actuated switching devices inclosed wholly in the boxes.

Electric Railway Current Collector, E. M. Roynton, West Newbury, Mass., 512,585. Filed Oct. 12, 1893.

Claim 1 follows :

In an electrically propelled bicycle car, the combination with the guide wheels of one or more current collectors guided and carried by the framework of said wheels.

Switches and Cut-Outs :—

Electric Cut-Out, A. P. Seymour, Syracuse, N. Y., 512,331. Filed Nov. 18, 1892.

Electric Switch, J. L. Hinds, Syracuse, N. Y., 512,614. Filed May 16, 1892.

Employs a pair of terminals attached to a base plate, a lever having contact faces to engage the terminals, and push buttons mounted on a lever.

Telegraphs :—

Printing Telegraph, E. A. Wirsching, 512,422. Filed May 12, 1893.

Relay, F. M. Locke, Victor, N. Y., 512,656. Filed June 19, 1891.

Employs a magnetic connection between the armature and the cores of the magnet to reduce the effect of residual magnetism in the latter.

Telephones and Apparatus :—

Electro-Magnet, F. R. McBerty, Downer's Grove, Ill., 512,386. Filed May 16, 1893.

Has for its object to produce a magnet responsive to alternating but not to continuous currents. Especially adapted to telephone annunciators.

Apparatus for Telephone Switchboards, C. E. Scribner, Chicago, Ill., 512,398. Filed Apl. 26, 1893.

Provides means for automatically switching the operator's telephone into and out of circuit with the plug circuit by means of which connection is established between lines.

Apparatus for Telephone Switchboards, C. E. Scribner, Chicago, Ill., 512,399. Filed Apl. 26, 1893

Provides means for resetting the annunciators electrically by a momentary current controlled by a key actuated in the performance of some act involved in the establishment of connection between lines.

Telephone Call Recorder, W. B. Thomson, Chicago, Ill., 512,413. Filed June 28, 1893.

Provides means whereby the number of the calling telephone may be recorded at the called telephone when the call is not answered.

Time Indicator Attachment for Telephones, C. Stever, San Jose, Cal., 512,454. Filed Mch. 24, 1893.

A GRAND TRUNK ELECTRIC RAILWAY.

IT has been proposed by a Mr. Corliss, of Haverhill, Mass., to run a double-track electric street railway from Haverhill to Nashua, N. H., running through Ayer village and Hudson. The distance is only about 20 miles in a reasonably straight line. The wide expanse of territory to be traveled over would necessitate a double track to accomodate the large population.

The system contemplates a power station at the Salem, N. H., depot. The electric cars will branch from it to Lowell and Lawrence, also coming from Nashua, Manchester, Chester and Derry. All these will pass and repass on the same double track from Salem depot, a central point, through Ayer village, thence through North Broadway to Haverhill city proper. Red electrics will also connect at Haverhill from Plaistow and Hampstead with electrics to points on the seashore—Salem, Beverly, Gloucester, Rockport, Plum Island, Newburyport and other places.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

JUDGE RICKS'S DECISION—HOW THEY LOOKED WHEN THEY HEARD THE NEWS.

WHAT THEY SAID: "WELL! WELL!! WELL!!!"

IS THE GENERAL ELECTRIC DOOMED?

The *New York World*, of Jan. 29, publishes the following extraordinary special dispatch:—

> LYNN, Mass., Jan. 28—Prof. Elihu Thomson, the inventor and main reliance of the Thomson-Houston Company in defending its patents, has declared war upon the General Electric Company, and, according to his associates, is to be one of a number of the original Thomson-Houston people to try to secure the big West Lynn plant for a new corporation which will manufacture under his patents.
>
> It is understood that Prof. Thomson declares he never sold his arc lamp to the General Electric people, and he claims to have another incandescent lamp which will drive the one now manufactured by the General Electric out of the market.
>
> Soon after the consolidation the Thomson-Houston people claimed the Edison people had misrepresented their assets, and they brought suits in this State, under various pretexts, to discover whether it were possible to divorce the original Thomson-Houston from the General Electric. They did not find a legal way to do this, and the determination to start anew followed. John Pevear, a local capitalist, is mentioned as the probable President of the new corporation.
>
> The original contract made with the General Electric 'made it obligatory on Prof. Thomson to offer all of his inventions to that company first, but it appears that the company has not kept its part of the contract and that the Professor prefers cash to promises. This is why he has not prepared to follow the caravan to Schenectady, and this is the reason why, he says, he "will make them sick."
>
> The factories of the General Electric here will close February 1 for an inventory, but it is not believed that they will reopen again as announced. Eighteen months ago there were nearly 4,000 persons employed at the West Lynn plant, but now only 500.
>
> The Thomson programme is war to the knife on the old concern and no alliance, friendly or otherwise, with any other corporation.

MR. H. F. PARSHALL, one of the leading designers of dynamos and motors, has, it is stated, resigned from the General Electric Co.

MR. SAMUEL INSULL and his brother Mr. Martin Insull have just returned from a brief trip to England.

MICA COMMUTATOR SEGMENT.

This is the age of realism in more than one direction. The trolley gives us real rapid transit until modified by real laws limiting its speed to less than that of horse cars; people with real capital manufacture real non-infringing lamps that are stopped by real injunctions sometimes with real stays attached, and so on *ad infinitum*. And now Messrs. Eugene Munsell & Co. of 214 Water street, New York, are sending to their friends real mica segments for commutators and rheostats, neatly pasted upon the pages of neat little pamphlets. This is wise. It is hard to draw a picture of a Munsell mica segment; well-nigh impossible, in fact, for not only is it perfectly transparent but its edges are so smoothly cut that one is not at all certain where they occur. We have tried to remove ours from the page and after splitting off upwards of nineteen or more perfect sheets have become tired and stopped; but there seem to be still plenty left.

The pamphlet also shows sizes and shapes of segments for various purposes always kept in stock, and is accompanied by a long price-list of mica sheets ranging in standard sizes from 1½ x 3 to 8 x 10 inches. There are also special larger sizes.

NEW RAILWAY EQUIPMENT FOR PHILADELPHIA.

THE GENERAL ELECTRIC COMPANY have secured a large slice of the street railway car equipment contracts awarded during the last ten days in Philadelphia. Of 250 contracted for by the People's Traction Company, 125 equipments with the G. E. 800 motors and type K controllers were purchased from the General Electric Company, while the remaining 125 were allotted to the Sperry Company, of Cleveland.

Of 80 equipments required by the Electric Traction Company, of Philadelphia, 70 will be furnished by the General Electric Company. The People's Traction Company had already contracted for three of the great 1,500 K. W. General Electric generators.

The General Electric Company have also secured contracts during the past week, covering:—20 car equipments for the Union R. R. Co., of New York; 25 car equipments for the Steinway R. R., of Long Island; 10 car equipments for the St. Louis Railway Co.; one 700 h. p. generator for the Steinway R. R. of Long Island; eight m. p. 300 K. W. generator for Cincinnati, Ohio.

A VALUABLE CANADIAN INDUSTRIAL LIST.

WE have received a copy of a Canadian work entitled "The Shipping Manufacturers' List" (560 pages), by M. J. Henry, Toronto. The work should be of great service to merchants and manufacturers of Canada who are buyers of Canadian goods. A supplement (48 pages) containing the names, business and post office address of all manufacturers in the above work is printed in pamphlet form, alphabetically arranged, for the use of those in the United States and other countries who wish to address Canadian manufacturers. A * indicates steam power. The price of both books is $3; or the supplement $1, mailed to any address on receipt of price. Address M. J. Henry, publisher, P. O. Box 384, Toronto, Ont. The book is a handsome quarto, and its get up is a credit to Canadian typography.

GRAPHITE LITERATURE.

ABOUT a year ago the Joseph Dixon Crucible Co., of Jersey City, issued a pamphlet on lubricating graphite. It embodied an elaborate scientific opinion by Prof. R. H. Thurston on the value of graphite as a lubricant, and much interesting information on the subject from practical men. The pamphlet has had a large circulation, and the company has been enabled to obtain from well-known men a vast amount of additional knowledge on the uses of graphite. Another pamphlet, twice the size of the former, will be issued early in February, and a copy will be sent free of charge to all interested in the subject of friction and lubrication.

THE ELECTRIC APPLIANCE COMPANY were well represented at the Milwaukee Convention of the North Western Electric Light Association by the President, Willard W. Low and by Mr. Frank McMaster, with samples of their leading specialties. The "Finest of the Wheat," a special circular for the convention setting forth the merits of the Standard push switch, Washington arc lamp, Packard "Mogul" lamp and Packard transformer, attracted considerable attention and was favorably received by the many station managers present.

MR. F. H. BADGER, JR., well known in Canada from his long connection with the Royal Electric Co., of Montreal, has resigned his position of superintendent of its lighting department and accepted that of general manager of the Montmorency Electric Power Co. of Quebec. This company is largely increasing the capacity of its system by the erection of a new station equipped entirely with new and improved machinery.

OPENING OF THE SAN FRANCISCO MIDWINTER FAIR.

Mr. W. F. C. Hasson, the electrical engineer-in-chief of the Midwinter Fair, of whose plant descriptions have already appeared in the Engineer telegraphs us as follows:—"Steam plant was set in working condition Thursday, January 25. The electrical illumination of the grounds is working successfully this evening of the official opening day."

SWAN LAMP MFG. CO.

The annual meeting of the stockholders of the Swan Lamp Mfg. Company was held at its offices in Cleveland, Ohio, on January 16th. The following officers and directors were elected :—S. H. Hamill, president and general manager; B. F. Niles, vice-president and treasurer; S. E. Cox, secretary and superintendent; B. P. Roberts, electrician. Directors: W. H. Lawrence, B. F. Niles, L. H. Rogers, Webb C. Hayes, S. H. Hamill.

WESTERN NOTES.

B. E. Sunny, general Western manager of the General Electric Co. left Chicago for a trip to Boston on Monday, the 22d inst.

The Chicago and Central Union Telephone Companies held their annual meeting in Chicago last week. The old boards of directors were re-elected and dividends of 12 and 5 per cent. respectively were declared on the capital stocks of the two companies.

Louisville, Ky.—The telephone exchange at Louisville, Ky., was entirely destroyed by fire on the 20th inst. The switchboard, with its 3,000 connections is a total loss. The estimated loss, including that on rentals, is $80,000. The insurance on fixtures was $25,000.

Chicago Electric Club.—The effects of the Chicago Electric Club were sold at auction on Wednesday evening last. The club some time ago decided to wind up its affairs and this is about the last of its official acts. Only a small amount was realized from the club's effects.

An electric light plant is to be erected by the Lake Street Elevated Railroad Company at 1137 West Lake street, Chicago. It will be one story and basement, 40x60 feet, and will cost $7,000. The current generated will be used for lighting the stations and their platforms and stairways.

Messrs. Sargent & Lundy have removed from their old offices on the 14th floor of the Monadnock Block to more convenient and commodious quarters on the ground floor of the same building where they expect to carry in stock a full line of Crocker-Wheeler motors for which they are the Western agents.

The Movable Sidewalk described in The Electrical Engineer some time ago is attracting considerable attention in Chicago, as a possible solution of the problem of affording rapid transit in the down town sections of the city, particularly as a loop circuit connecting the various terminals of elevated and cable lines. Prominent citizens are identified with the movement.

Chicago Telegraphers.—The annual meeting of the Chicago Telegraphers' Aid Society was held last week at Lincoln Hall, Chicago. The report showed disbursements of $1,747 in sick benefits during 1893. The treasury contains a balance of $1,000. The membership is 300. C. W. Potter was elected president; C. L. Clevenberg, vice-president; W. H. Mills, secretary, and W. E. Griffiths, treasurer for the ensuing year.

For Western Electric.—The United States Court of Appeals composed of Judges Jenkins, Grosscup and Seaman, which met in Chicago last week overruled the motion for a rehearing in the case of the Western Electric Co. against the Sperry Electric Company for infringement of patents on electric lamp improvements. The court held that there was no ground for a rehearing. The case was decided some time ago in favor of the plantiff.

Wilbur F. Davidson, of Port Huron, Mich., who is general agent for the state of Michigan for the General Electric Co. has just been given a verdict in a Chicago court for $43,000 damages against the Illinois Central Railroad Co. On Feb. 27, 1893, while Mr. Davidson was alighting from a train at 53d street, at a point where the railroad tracks were then being elevated, he was caught between trains and received injuries about the back and hips from which he has never fully recovered.

The Chicago Edison Company, of which Samuel Insull is president, has issued a call for a special meeting of the stockholders on Feb. 21, for the purpose of voting on a proposition to increase the capital stock from $3,000,000 to 5,000,000. The funds to be derived from the new issue will be used for various improvements and extensions, particularly on the West side. The directors expect to use $1,200,000 in this way during 1894. One of the directors is authority for the statement that the plans contemplate the entire abandonment of the Adams street station and the fitting up of the Harrison street station in such a manner as to greatly reduce the cost of production.

A TRIUMPH FOR "CHICAGO ELECTRIC" WIRE.

The Goodyear Hard Rubber Co., 9 Mercer street, New York, sole agents for the Chicago Electric Wire feel considerably elated over the fact that they have been awarded the contract by the United States Government for 75 miles of submarine cable, now being made and intended for the very exacting work of Torpedo service. Mr. P. Campbell, of the company informs us that the tests were of the most thorough nature and that the cable has withstood the ordeal at every stage. As the government has hitherto, for some prejudice or other, deemed it necessary to go abroad for its cable, Mr. Campbell looks upon this contract as a great triumph and as another proof that American cable is now fully equal, if not superior, to any made in Europe. The samples shown us by him are certainly very fine.

THE BRISTOL CO.

The Bristols' Mfg. Co., of Waterbury, Conn., announce the incorporation of their company under the name of The Bristol Co. This company manufactures recording instruments for various purposes. Their recording voltmeter is meeting with considerable favor among lighting and railway stations. One concern in St. Louis has eleven of the instruments in use.

NEW YORK NOTES.

Mr. W. H. McKinlock, of the Metropolitan Electric Co., Chicago, favored the office of The Electrical Engineer with a long call last week, when the electrical situation was pretty thoroughly discussed. He takes a very hopeful view of the outlook, does not believe in a hasty recovery but in a very steady and marked return to normal conditions of activity. The Metropolitan incandescent lamp is a pronounced success, and is enjoying a large demand.

Commodore P. Vedder, "a graduate of the towpath," well-known in legal practice in this state, and also as State Assessor, U. S. Register in Bankruptcy, Assessor of Internal Revenue, etc., and more lately as President of the New York and New Jersey Ice Lines, has been chosen general manager of the Cataract General Electric Company—a position of great importance and responsibility in which his intimate acquaintance with canal matters will be of the greatest value.

The Newton Electric Co., Taylor Building, 39 Cortlandt St., have purchased the business recently conduced by the Imperial Electric Co. and will manufacture and sell all the specialties which they controlled in connection with a general line of lighting appliances. The Newton company have increased their capital stock to $15,000 cash and Mr. W. J. Newton, their general manager, tells us they intend doing a much more extensive business this year. They are certainly getting ready for a large trade with a number of excellent specialties and novelties, especially as applied to incandescent lighting.

NEW ENGLAND NOTES.

Perkins Electric Lamp Company.—It is expected that this company may soon again be heard from, as it is understood that on the strength of the recent decision by Judge Ricks in Cleveland, they will at once apply for a dissolution of the injunction under which they were placed about a year ago.

The Pettingell Andrews Company of Boston, have just secured the exclusive agency for New England, of the famous P. and B. paint, manufactured by the Standard Paint Company, of New York. They report now that business is getting quite brisk, and they are having large sales in their other specialties, especially in tubing of the Interior Conduit Company of New York, and the well known standard specialties of Okonite wire.

The Beacon Vacuum Pump & Electrical Company of Boston, are busily engaged in sending out large quantities of their perfected lamp which is giving now entire satisfaction to the consumer. The new Beacon lamp possesses, as every one knows, many new features, and many difficulties were encountered in giving the public a lamp which could be depended upon, as new principles were involved in its construction. The experimental stage is entirely past, and the Beacon lamp, as now manufactured, gives excellent satisfaction. It is a marked improvement on their previous manufactures. The Beacon Company are so well satisfied with their new lamp, and find it so easy and economical to manufacture, that they will not at present, even since hearing Judge Ricks' decision in Cleveland, apply for a dissolution of the injunction served on them some months ago. They claim that the lamp is just as good as, if not better, than the old Beacon, is cheaper to manufacture, and that they can consequently give their customers, just as satisfactory an article at a very much reduced figure.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XVII. FEBRUARY 7, 1894. No. 301.

THE TELEPHONE PATENT SITUATION.—IV.

WHERE a transmitter is employed that uses an induction coil, the claims of the Watson patent would seem to cover the simplest switching devices in which springs are used, whether automatic or not; where no induction coil is used, however, there is no primary circuit as distinguished from a secondary circuit and it would seem unnecessary to infringe these claims. There are numerous minor support patents, all of which are subordinate to the patents already mentioned and which are hardly worth referring to in this article. There are, however, a few interesting devices which can scarcely be held to be subordinate to these patents, and which will be of interest to inventors. One of these is the patent of Sigmund Bergmann, of October 31, 1882, No. 266,750, the claims of which are as follows:

1. The combination, with a telephone-receiver (or transmitter) and a supporting device thereof, of a switch and contacts, and a permanent magnet and armature moving such switch, and brought into action by the attaching of such instrument to such supporting device, substantially as set forth.

2. In a telephone-switch, the combination, with a polarized switch-lever, of the movable instrument having an iron ring carried thereby, substantially as and for the purpose set forth.

3. In a telephone-switch, the combination, with a movable instrument provided with an armature, of a pivoted horseshoe-magnet provided with contacts and acting as the switch-lever, substantially as set forth.

The device covered by the claims above is certainly not subsidiary to the patents hereinbefore mentioned as the moving force is magnetism and not gravity or the pressure of the hand. Neither could the patent of Samuel H. Bartlett of October 7, 1884, No. 306,050, be said to infringe any of the patents thus far alluded to in this article. The following are the 1st and 2d claims of the Bartlett patent:

1. An electrical conducting-cord having a switch device contained therein, substantially as described.

2. An electrical conducting-cord composed of two or more wires bound together, having a switch device contained within the body of the cord, substantially as described.

Mr. Ezra T. Gilliland in his patent No. 237,971 of February 22, 1881, shows an ingenious, if not very practicable, method of solving the telephone support problem. His claims are brief and the first well describes his invention, viz.:

In combination with a telephone, two posts or parts formed with cavities in their adjacent faces, and a ball which is inserted in said cavities, said cavities having a formation, substantially as described, by which said ball is caused to establish an electrical connection between said parts when the telephone is in one position, and to break said connection when it is in other positions, substantially as and for the purposes set forth.

Another interesting device is that covered by the patent of the joint inventors, W. H. Eckert, J. A. Seely and E. A. Eckert. There are only two claims to this patent, which is dated October 24, 1882, and is numbered 266,277. The 2d claim is as follows:

2. In a telephone circuit, the combination of a receiving telephone having keys upon its body with a separate transmitter and battery, arranged as described, whereby when the receiving telephone is grasped by the listener the keys can be operated to switch the receiving and transmitting telephones and battery into the line circuit.

Mr. S. Bergmann has also contributed another interesting and ingenious device to the collection of telephone support switches; the invention is covered by his patent of December 28, 1880, No. 235,988. The following are the claims in full:

1. The combination of a telephone-instrument, a support for said instrument when it is not in use, means which preclude the placing of the instrument on the support or its removal from the support without a movement of the support by the hand, and a switch which is operated simultaneously with the movement of said support to connect the instrument with or disconnect it from the electric circuit or line with which it is used, substantially as specified.

2. The combination of a telephone-instrument, a bolt adapted to be operated by hand and serving to support the instrument when it is not in use, means which preclude the placing of the instrument on or the removal of the instrument from the bolt without a movement of said bolt, and a switch operated by the movement of the bolt to connect the instrument with or disconnect it from the electric line or circuit with which it is used, substantially as specified.

3. The combination, with a bolt upon which a telephone-instrument may be hung and a switch operated by the movement of the bolt, and serving to connect the instrument with and disconnect it from an electric circuit or line with which it is used, of a pair of jaws or devices extending transversely to the bolt, substantially as and for the purpose specified.

4. The combination, with a bolt upon which a telephone-instrument may be hung and a switch operated by the movement of the bolt, and serving to connect the instrument with and disconnect it from an electric circuit or line with which it is used, of a pair of jaws or devices extending transversely to the bolt, and a cross bar or bars extending between said jaws or devices, substantially as and for the purpose specified.

5. The combination, with a bolt and a switch operated by the movement of the bolt to connect a telephone-instrument with or disconnect it from an electric circuit or line with which it is used, of an eye on the telephone-instrument, whereby it may be attached to and supported on the bolt by slipping the bolt through said eye, substantially as and for the purpose specified.

Another patent of Messrs. W. H. Eckert, J. A. Seely and E. A. Eckert, dated March 3, 1885, No. 313,409, is also interesting. The first claim which fairly describes the invention, is as follows:

1. The combination with a telephone-station apparatus, of a switch, consisting of a movable plate carried by the receiver and supported in front of the ear-piece thereof, and contacts and connections arranged so that said switch is shifted to connect in the telephone apparatus by application of said receiver to the ear, substantially as described.

This article in our series might be continued at great length to deal fully with the details of the minor telephone support patents; it will probably be sufficient, however, after having taken up the principal ones, to direct attention to a few patents not already mentioned, in order that those interested in the matter may see how thoroughly the subject of automatic telephone supports has been covered. Among these remaining support patents are the following: Jos. R. H. Hinton, Feb. 21, 1888, No. 378,250. Wm. C. Turnbull, Sept. 7, 1886, No. 348,936. Wm. C. Turnbull, March 30, 1886, No. 338,889. T. A. Watson, Oct. 10, 1882, No. 265,897. John C. Francis, Jan. 3, 1893, No. 488,993. Chas. W. Lewis, Oct. 24, 1882, No. 266,374. Milo G. Kellogg, June 28, 1881, No. 243,575. Chas. W. Lewis, Oct. 24, 1882, No. 266,295. Henry W. Cozzens, June 6, 1882, No. 258,894. Charles E. Scribner, Oct. 25, 1881, No. 248,671. John D. Lyle, Dec. 23, 1884, No. 309,791. T. A. Watson, Nov. 5, 1878, No. 209,592. Henry W. Comstock. June 9, 1885, No. 319,789.

THE COPPER-ZINC ACCUMULATOR.—III.

BY

Dr Paul Schoop

It may be well now, to try to explain why the Desmazures accumulator has not as yet met with that success, which a reliable traction cell is bound to do. In describing the Lalande cell, the probable chemical reactions during its discharge have been set forth. The whole difference between the Lalande cell and a fully charged Desmazures accumulator is, that the latter contains not *oxide* of copper, but *suboxide* of copper. A Lalande cell might, partially discharged, represent exactly the same galvanic combination as the fully charged Desmazures cell. But the main trouble in the accumulator rests with the *charging*; it will be necessary therefore at this point to look into the reactions which are involved in the charging process in order to understand the difficulties connected with it.

When the Desmazures cell is fully discharged, there is pure, porous copper on one side and a pure steel sheet on the other side, while the electrolyte contains water, caustic potash, zincate of potash (zinc-oxide, dissolved in caustic potash, forms a chemical compound, called zincate of potash), and mercurate of potash (hydro-oxide of mercury dissolved in potash).

If a current is now passed through the cell in the right direction making the copper side the anode and the steel side the cathode, perhaps the following reactions might occur: Caustic potash is decomposed, leaving on the steel sheet potassium and at the copper side a higher oxidized compound, perhaps the hydrate of peroxyde of potassium, corresponding to the better known compound, called peroxide of hydrogen. But neither of these compounds can exist under the present conditions; the potassium at once precipitates zinc out of the zincate of potash, this zinc being deposited on the steel sheet (cathode), the potassium combining with the rest of the broken zincate of potash molecule and forming caustic potash. The peroxyde of potassium, too is decomposed into ordinary caustic potash and oxygen, the oxygen being at once absorbed by the porous copper and suboxyde of copper is formed. Now the peroxyde of potash, at low temperatures, is a pretty stable compound providing the caustic potash solution be concentrated, and does not decompose very easily. Besides, it may be that the electrolysis of caustic potash, at low temperature forms more complex compounds of potassium, oxygen and hydrogen,—compounds, which contain oxygen in a different state of activity. Whatever the case may be, the porous copper does not absorb so readily the oxygen of these compounds. Instead of the simple and desirable product of suboxide of copper, other compounds of copper are simultaneously formed, compounds containing more oxygen, for instance, oxide of copper, hydrates of oxide of copper and perhaps salts of cupric acid.

It has not been made known what the blue-colored soluble compound really is, which is formed when the copper accumulator is charged with the usual density of current at low temperatures.

It will be seen from the above, that the charging of the copper accumulators depends a good deal upon the temperature at which the process takes place. In this respect, the old lead accumulator is less troublesome, since it may be charged at any temperature reigning throughout the year without giving rise to trouble. Temperature has also some influence on the lead accumulator, but it does not interfere with the practical service very much.

It is a matter of fact, that the charging process at the copper anode with the copper accumulator has to be carefully watched and several conditions must be kept within certain limits; if not, the whole service of the accumulator might be disturbed.

But not only does the copper side of the battery give rise to drawbacks, but the cathode or zinc side also. Electro-metallurgists know, that the deposition of zinc in a coherent, firm and metallic form is not at all an easy task. First of all, the surface, on which the zinc is to deposit, must be pure and metallic; the least superficial oxidation hinders the adherence of the zinc deposit. The mercury, added by Desmazures to the electrolyte, has for its purpose to amalgamate the steel sheet and thus to facilitate the adherence of the zinc deposit. It may be further stated, that the nature of the deposited zinc depends upon the temperature of the electrolyte, the percentage of zinc the electrolyte contains, the density of current, the circulation of the electrolyte and other conditions. It will be seen again, that the charging process of the zinc side is not so simple by far, as it is with the old lead cell. To sum up: The management of the copper accumulator is much more difficult at present, than that of the lead accumulator, so far as the Desmazures accumulator is concerned.

The Phillips-Entz Accumulator.—This type of copper-zinc battery is the latest perfection of the alkaline accumulator It has been described before by the inventors and need be only briefly cited here. The improvement relates mainly to the anode or copper electrode. As is known and more fully described in the patents granted by the U. S. Patent Office, the copper electrode consists of a copper cable, made in the following way: Round a central wire is loosely woven fine copper wire and the space between this loose wire netting is filled with a paste, made of a mixture of finely ground oxide of copper and sulphur. Afterwards the whole is exposed to nearly red heat and then a braiding of asbestos applied to the pasted cable. The sulphur is burnt out by the oxygen of the oxide of copper and pure copper in a highly porous state remains. The copper cable is then wound into the form of a mat, provided with insulators and a connection piece and is now ready for use in the cell. In the finished element, the containing vessel forms part of the cathode and the steel sheets, forming the cathode are put in electrical connection with each other by means of the sheet steel vessel.

Some data, obtained by the writer during an investigation of some accumulators of the Phillips-Entz accumulators (the investigation was made in August, September and October, 1891) may be of some interest.

Weight of anode (copper electrode)........	2	lbs.	18	ounces.
" " cathode (two steel sheets)......	1	"	1	"
" " vessel, including connections..	1	"	10	"
" " electrolyte..............,.......	8	"	8	"

Weight of complete cell, about 9 lbs.

The capacity of such a cell was, at a discharge rate of 20 amperes, about 80 ampere-hours. The voltage was 0.77 volt on an average during discharge; or the capacity in watt hours was 61, at a current giving 15.4 watts output. The charging was effected with a current of 10 amperes during 10 hours; the voltage was 0 90 volt at the start and 1.05 at the end of the charge. Both the charge and the discharge were performed at a temperature of about 130° F, these directions having been given by the inventors. It had been found that the capacity of the cells varied according to the rate of the discharging current and that the resistance and therefore the efficiency varied considerably according to the temperature of the accumulator.

To avoid the absorption of carbonic acid from the air, a layer of paraffine oil was applied on the surface of the liquid. The cells were neatly manufactured and yielded more electric energy than any of the known types of lead-accumulators. The main question and one, the importance of which ranks above all others,—reliability of the service of the cell,—is that of durability. In this respect, an experience of only some weeks or months is hardly sufficient and this point is perhaps only known to the manufacturers of this type of battery. One would imagine, however, that, if the carbonic acid of the air or dust cannot enter into the cell, and if the proper attention is applied in charging, at least the same durability, or even a greater, could be obtained than with the lead-accumulator. The handling of the Phillips-Entz cell is no doubt a little more complicated than that of a lead accumulator. Everything considered it must be said that the practical work of those batteries, installed for traction purposes by the inventors, alone can decide and prove the superiority of this type.

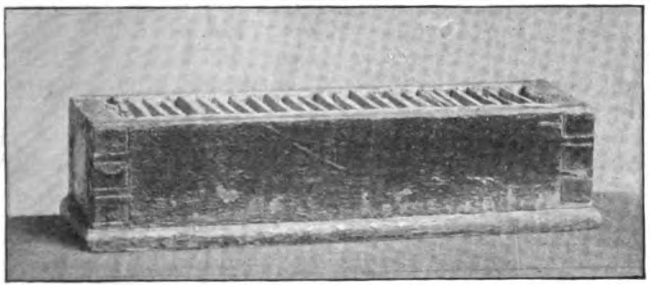
THE ELECTRO-MAGNET; or JOSEPH HENRY'S PLACE IN THE HISTORY OF THE ELECTRO-MAGNETIC TELEGRAPH.—V.

BY

Mary A. Henry

We have come to a very important day in the history of the telegraph.

We have seen in the last chapter how the magnet grew under Henry's hands until it could lift fifty times its own weight, and how, when it had seemed to come to the limit of its power, Henry had conceived another method of winding the wire on the iron, so as to form an instrument of still greater strength. Did Henry neglect his first child for this its new, strong brother? Not so, and it was well, for it had its secret, which on this day it revealed. When it failed to respond to his demands beyond a certain length of wire, the question of the relative capacity of different lengths of wire to transmit the electrical current immediately seized upon his mind, and it was to test this that he undertook a series of experiments on this memorable day.



PROF. HENRY'S "COMPOUND" BATTERY.

It was the year 1829, and July was just ending or August just begun. As Henry entered the Academy building he directed his steps to a long room or hall—used for the public ceremonies of the institution—where the experiments were to be made; and where, he says —"1060 feet, a little more than one-fifth of a mile of copper wire of the kind called bell-wire, .045 of an inch in diameter were stretched several times across the large room."[1] We may not attempt to give in detail all the experiments, although only a few of them were recorded. We confine our attention to one of them and the steps which led to it; the one in which Henry made the combination which constitutes the telegraph; the only combination possible for the telegraph, now as then. Not by accident was this combination made; it was the necessary result of the process of research. What was the combination? A magnet, a battery, and that long wire around the room. *The magnet*:—it was not the stronger one of many coils, but the first, of one long coil, with its secret which there and then it revealed, and this was the secret:—that it possessed the subtle power of being excited by electricity from a distant source. *The battery*:—it was not one of a single pair of plates, such as we have seen Henry using, but a compound battery of many plates, shown in Fig. 1. It too had its secret, which it too then revealed, viz.:—that a current of electricity from it could act upon a magnet through a wire of any length, as easily as if attached directly to the magnet, provided it had this particular magnet to act upon. But we are anticipating. Let us see how Henry made this combination.

We have seen that hitherto his attention had been confined to the lifting power of his magnets, and that his aim had been to produce the greatest magnetic effects with the smallest expense of galvanic power. We have seen him working constantly with a single pair of galvanic plates, and these very small. On this day he was to see how his magnets could act at a distance. The object of his experiments was to investigate—by means of different lengths of wire, and batteries of different strength—the resistance of the wire to the electric current. Besides single plates of various size, he had ready a compound battery of *twenty-five plates*, arranged in a trough, as we have said. The resistance of the wire to the electrical current! We recognize in it the old, old difficulty in the way of the telegraph. Henry about to investigate it, was in fact face to face with the recreant electricity, to demand of it why in all these years it had baffled the world by failing to act at a distance. His assistant in the experiments to be made was a young man of his own age Dr. Philip Ten Eyck, of Albany.

He began the experiments with the same small pair of plates we have seen serving him so well, two inches square. He used at first a galvanometer to tell whether the electric current could exert any effect, acting through a long wire stretched back and forth across the room.

"From the mean of several observations the deflection of its needle was 15 degrees." Then Henry substituted the magnet of a single coil. This magnet, so ready to respond hitherto to the action of these two plates—would it do so through this one-fifth of a mile of wire? "The magnetism was scarcely observable in the horse-shoe." Was the old world right; was the galvanic force unable to act through any great length of wire?

> "The small plates were removed" and larger tried, "a battery composed of a pair of zinc plates 4 inches by 7 inches, surrounded with copper was substituted. When this was attached immediately to the ends of the 8 feet of wire wound round the horse-shoe, the weight lifted was 4½ lbs: when the current was passed through the whole length of wire (1060 feet) it lifted half an ounce."

Again the result seemed to say that galvanic power could not overcome the resistance of a long wire.

Did Henry try still larger plates? Had he made them many times the size, the result would have been relatively the same. He abandoned the battery of a single pair of plates; the compound battery of many plates stood there in its trough, and then was made the experiment which gave the telegraph. Let us give it in Henry's own words.[2]

> "*Experiment* 7. The whole length of the wire was attached to a small trough on Mr. Cruikshank's plan, containing 25 double plates and presenting exactly the same extent of zinc surface to the action of the acid as the battery used in the last experiment. The weight lifted in this case was 8 oz.; when the intervening wire was removed and the trough attached directly to the ends of the wire surrounding the horse shoe it lifted only 7 oz. *From this experiment, it appears that the current from the galvanic trough is capable of producing greater magnetic effect on soft iron after traversing more than ⅕ of a mile of intervening wire, than when it passes only through the wire surrounding the magnet.* It is possible that the different states of the trough, with respect to dryness, may have exerted some influence on this remarkable result, but that the effect of a current from a trough, if not increased, is but slightly diminished in passing through a long wire, is certain. A number of other experiments would have been made to verify this had not our use of the room been limited, by its being required for public exercises.

---

[1] *Silliman's Journal*, Jan., 1831—Vol. XIX.

[2] *Silliman's Journal*, Vol. XIX, or Writings of Joseph Henry, Vol. I., p. 41—Smithsonian Contributions.

> **"On a little consideration however, the above result does not appear so extraordinary as at first sight, since a current from a trough possesses more "projectile force," to use Prof. Hare's expression, and approximates somewhat in intensity to the electricity from the common machine. May it not also be a fact that the galvanic fluid, in order to produce the greatest magnetic effect, should move with a small velocity, and that in passing through one fifth of a mile, its velocity is so retarded as to produce a greater magnetic action: But be this as it may, the fact, that the magnetic action of a current from a trough is, at *least*, not sensibly diminished by passing through a long wire, is directly applicable to Mr. Barlow's project of forming an electro-magnetic telegraph; and it is also of material consequence in the construction of the galvanic coil. From these experiments, it is evident, that in forming the coil we may either use one very long wire or several shorter ones as the circumstance may require: in the first case our galvanic combinations must consist of a number of plates so as to give 'projectile force'; in the second, it must be formed of a single pair."**

How simple are the words which tell, as if it were some unimportant matter, that the circuit was at last formed in which electricity would not fail; but not only had Henry's magnet responded to that battery through all that length of wire more easily than when magnet and battery were in immediate contact; the closing words of the paragraph quoted show that Henry had fully recognized the cause of the phenomenon. He had made the great discovery of the law of relation between the "projectile force" in the battery and the resistance in the coil.

He knew the importance of what he had accomplished; he says:—

> **"This was the first discovery of the fact that a galvanic current could be transmitted to a great distance with so little diminution of force as to produce mechanical effects; and of the means by which the transmission could be accomplished. I saw that the electric telegraph was now practicable; and in publishing my experiments and their results, I stated that the fact just mentioned was applicable to Barlow's project of such a telegraph. I had not the paper of Barlow before me, and erred in attributing to him a project of a telegraph, as he only disproved, as he thought, the practicability of one. But the intention of the statement was to show that I had established the fact that a mechanical effect could be produced by the galvanic current at a great distance, operating upon a magnet or needle, and that the telegraph was therefore possible. In arriving at these results, and announcing their applicability to the telegraph, I had not in mind any particular form of telegraph, but referred only to the general fact that it was now demonstrated that a galvanic current could be transmitted to great distances with sufficient power to produce mechanical effects adequate to the desired object."**

So they were brought together for the first time that day,—the battery which could act at a distance and the magnet which could be acted upon at a distance. The magent was Henry's; he had endowed it with its subtle power. The battery was not his; but he had discovered its latent power and how to awaken this by calling in the aid of his own child.

In the telegraph of to-day the magnet used to receive the message is the same as the magnet used in the combination formed that day in Albany. The battery is essentially the same, but the one fifth of a mile of wire has stretched to many miles, even to the three thousand that lie between the shores of the ocean; and Henry's magnet answers as easily to the electric effects of the battery through all this distance as it did there in that room. The discovery made that day was to effect the world.

How do we know the date of these experiments? Henry published his account of them in *Silliman's Journal* of Jan. 1, 1831. He does not say positively, in that paper, whether they were made in 1829 or 1830, and why we place it in 1829, we will tell a little later. For the month we refer the reader to a casual remark of Henry which we have quoted. He says: "A number of other experiments would have been made to verify this had not our use of the room been limited by its being required for public exercises." These public exercises took place on the annual exhibition day of the academy; they consisted in speeches and other exercises by the pupils; and were attended by the parents of the boys and the friends of the institution. It was the great day of the year for the Academy. According to the records it was the 9th of August in this year, 1829. The three or four days preceding it were devoted to examinations of the pupils, also open to the public. In was on the 5th of August this year that Henry's classes were examined. As in the interest of the experiments Henry, as he indicates, would have retained the room as long as possible, we place the experiments in one of the first two or three days of the month of August or in one of the very last days of July.

The small trough battery used is now in the National Museum at Washington. It not only told Henry that day that electricity could act at a distance; it led him to another discovery. In the course of the experiments, the poles of the battery had been connected with a long wire. As Henry detatched one end of this, from wire to battery flashed a brilliant spark. This was a beautiful invitation to research in a new field. It was Henry's first intimation of the phenomenon of self-induction or the "extra current" as it is called. Henry says: "My experiments on the transmission of power to a distance were superseded by the investigation of a remarkable phenomenon, which I had observed in the course of these experiments, of the induction of a current of a long wire on itself, and of which I made first mention in a paper in *Silliman's Journal* in 1832, Vol. xxii." As soon as he had made a practical test of his discovery in regard to the telegraph he accepted the invitation of the spark, and so began investigations, which were at intervals continued in Albany and Princeton, until he was called to the charge of the Smithsonian Institution. That bright spark is of particular interest just now, since it is on account of the investigations it prompted that Henry's name has been given to the unit of inductance.

The evening of the eventful day had come, and Henry went home to receive that sympathy which from the constitution of his nature was especially essential to him in everything. "Sympathy is, with the man of genius especially (and in a measure with all men) an intellectual want as necessary as the coarsest elements of existence. I can bear testimony to the truth of this saying." These are Henry's words.

BI-METALLIC TELEPHONE CONDUCTORS.

BY

A. E. Kennelly

Concerning bi-metallic telephone wires, it appears to the writer that any proposition which asserts that a combination of two metals in a conductor is superior for telephonic purposes to a similar conductor of either metal alone,—seems to be entirely new, deserves to be considered with circumspection, and lays the burden of proof entirely upon experimental evidence.

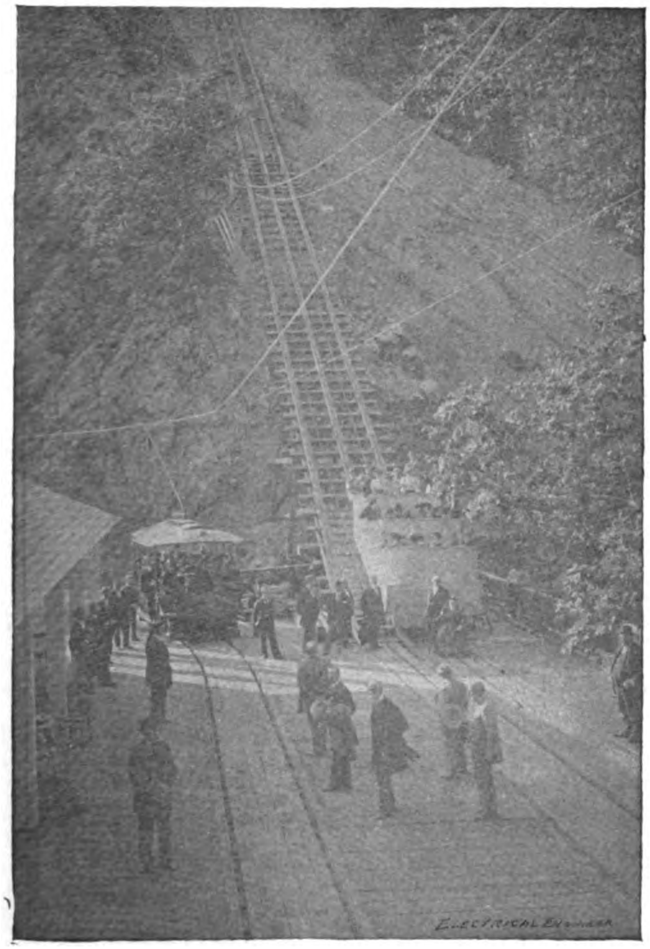
In the case of iron, however, it is orthodox to suppose that the inductance possessed by an iron wire is advantageous in long distance telephony within reasonable limits if the resistance of the conductor were at the same time capable of being sufficiently reduced. Also that when a definite adjustment between inductance, resistance, and capacity of the conductor has been attained, it is consistent with present recognized views to suppose that a comparatively low insulation can be permitted. In this connection lies the possibility for a superiority of a compound iron-copper wire over one wholly of copper or of iron; but even then the advantage, if due to these reasons, should attend definite relations of composition and disposition in the wires and not iron-copper wires indiscriminately.

MR. MAXIMILIAN MINTZ.

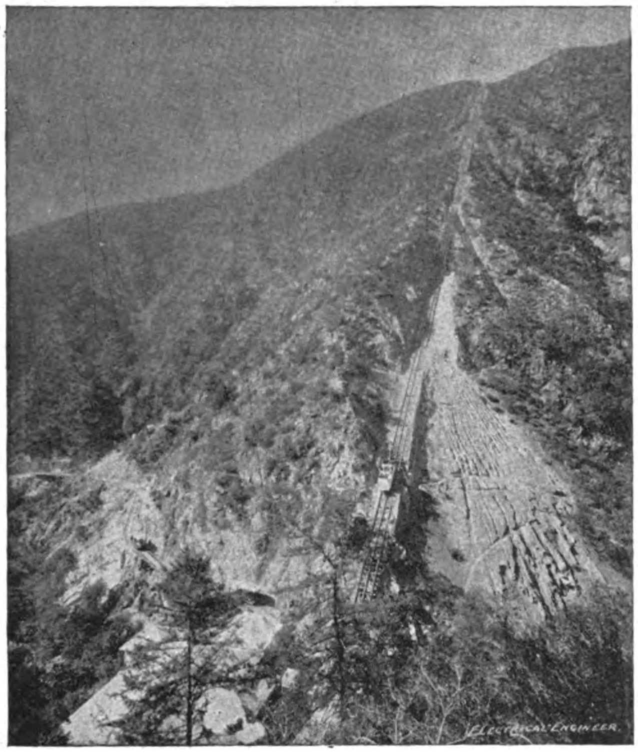
A CORRESPONDENT inquires for the address of Mr. Maximilian Mintz, representative of the Grob petroleum engine. Replies may be addressed to this office.

ELECTRIC TRANSPORTATION DEPARTMENT.

FROM STRAWBERRIES TO SNOW BY THE MOUNT LOWE ELECTRIC ROAD.

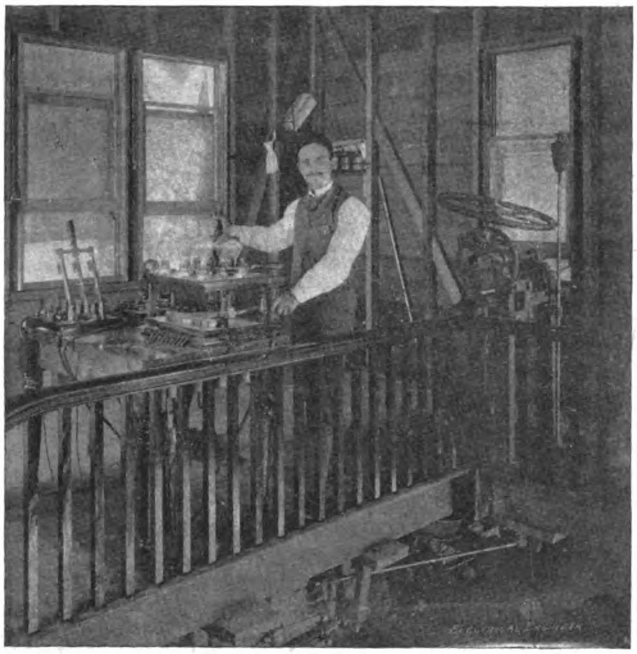


Foot of Great Cable Incline Operated by Electric Motor, Mt. Lowe Railway.



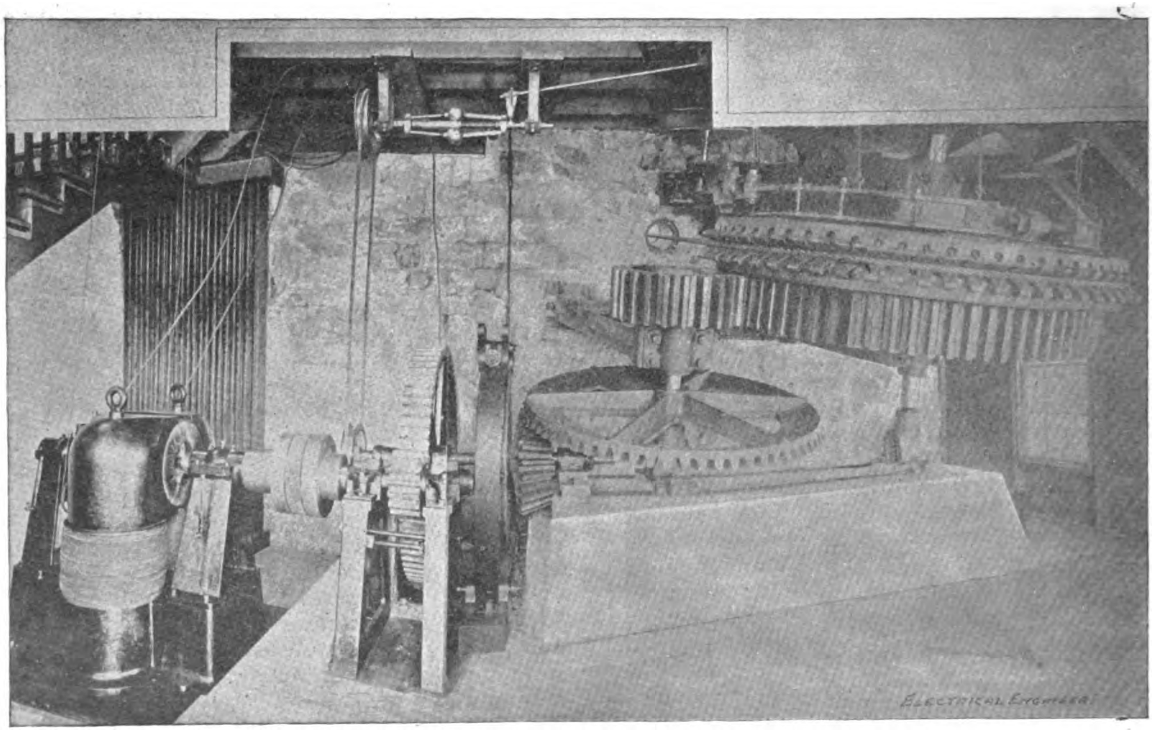
Junction of Trolley System and Cable Road.

THE electrical engineer who is fortunate enough this Spring to visit the California Midwinter Fair is likely to enhance the pleasure of his westward journey by a trip into Southern California. Should he do this, as many another tourist has already done before him, he will discover that the attractions of the Los Angeles region have been greatly added to in a manner that will appeal to him not less from the technical than from the æsthetic standpoint. Some nine miles from Los Angeles, and nestling at the feet of the Sierra Madre range, is the young and beautiful city of Pasadena, which has gathered itself into the lap of the hoary mountain very much as the fair Shunnamite cherished old King David. Of course the city is ornate with orange groves and flower gardens; that we all expect of even the smallest and least ambitious South California community; but one is hardly prepared for such a wealth of it or for so many evidences of substantial prosperity in the more utilitarian forms of brick and mortar, paved streets, opera house blocks and the latest styles in dry goods. Back of all and above all tower the dark slopes of the mountains crested with snow at this season of the year, and the greatest charm of Pasadena is that through the energy of a leading citizen, Prof. T. S. C. Lowe, and with the help of electricity, the summits of the range have been made easily accessible. From Mount Lowe, an altitude of 6,000 feet, or even from Echo Mountain, 3,500 feet high, we command a view of extreme beauty, with snow capped mountains for a background; deep green valleys right and left—the San Gabriel, the San Fernando and others; and far away, across thirty miles of poppy field, calla lily beds, and fruit orchards, the Pacific Ocean. If it were night, we could see the distant rows of white arcs in the streets of Los Angeles, and the flash of the light house on the island of Santa Catalina, 60 miles away. Prof. Lowe, in a most ingenious and original manner has built a combined electric and cable road, opening up to travel this region of airy enchantment. Switzerland has lately seen something of the kind attempted in the electric road which runs in sight of the Jungfrau to the new Lauterbrunnen hotel from the top of the cable road, out of the valley; but Prof. Lowe starts from the Pasadena Valley with an electric road operated by gas engines; then operates a section of steep cable road by electric motor energized from the same power plant; and at the end of that has another electric road. The features of such a piece of engineering are, as we have already intimated, worthy of notice, and it is equally deserving of mention in such a journal as this that Prof. Lowe, distinguished for his ballooning exploits during the Civil War and for the gas system he invented and introduced, was the first to propose and assist in carrying out the combined operation of gas and electric lighting plants now so common but once so bitterly resisted. It need not surprise us that such a man, familiar with the enormous development of mountain travel and mountain hotels in the Swiss Alps



Regulating Apparatus for Cable Incline, Mt. Lowe Railway.

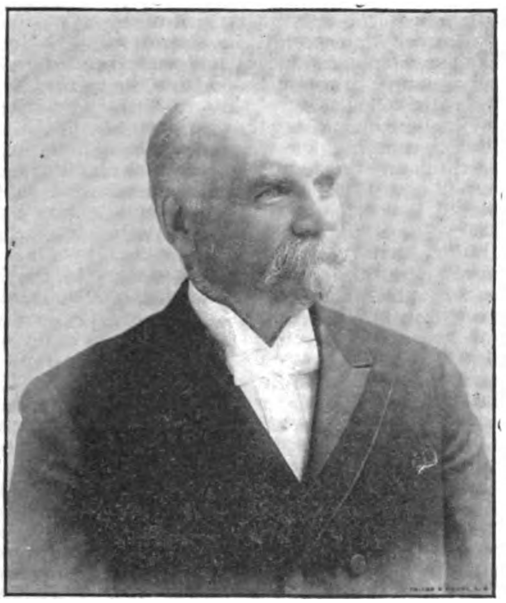
should have spent a large fortune in developing successfully the same means of recreation for Americans in the Pasadena Alps of Southern California, where tropical resources of pleasure abound that are not available in the playground of Northern Europe.



Electric Motor and Cable Operating Apparatus, Mt. Lowe Railway.

The ascent from the valleys is easy. Pasadena itself is about 800 feet above sea level, and Altadena Junction, where the Los Angeles Terminal Railroad delivers its passengers to the Mount Lowe trolley road, is about 1,000 feet high. Thence the trolley line runs by easy grades, nowhere exceeding 7½ per cent, to the Rubio Pavilion nearly 3 miles away, at an altitude of about 2,200 feet. This trolley section is well built, with bracket suspension of the trolley wire, and the track construction is excellent, as it need be in view of the large amount of curve of short radius. There are no fewer than eleven solid timber bridges on the stretch from Altadena to Rubio. Part of the road here had to be cut through solid granite by men who dangled in mid-air from ropes while they drilled and blasted. The little power house at Altadena is novel and interesting. It comprises two Otto gas engines of 60 h. p. each, capable of working up to 140 h. p. together. These drive an Edison generator of corresponding capacity, and a duplicate plant is held in reserve. Gas for fuel is made from gasoline, the carburetter and storage tank being situated near by. It is proposed, however, to utilize water power for the work by means of Pelton wheels installed at Rubio Pavilion, at the foot of the Great Cable Incline, and the water pipes for this system are already laid and final arrangements nearly completed. Current is not only furnished from Altadena to the trolley road direct but is also delivered to a Keith motor of 75 h. p. which drives the mechanism of the cable road; so that we have the unique instance of electricity running a trolley road and a cable road at one and the same time from the same plant.

The trolley road ends at Hotel Rubio, which stands in Rubio Amphitheatre, a beautiful and romantic spot graced with no fewer than eleven waterfalls the power of some of which is already utilized in lighting the Great Cable Incline and the two hotels built for the accomodation of patrons of the road. Here starts the Great Cable Incline, about 3,000 feet long, rising about 1,300 feet, and unrolling in its ascent a magnificent panorama of mountain, valley and sub-tropic vegetation. This Incline is double track, the inner rail serving as one side of either of the tracks, and the cars passing each other on a four rail turn-out about half way up. There are two cars, which are permanently attached to an endless wire cable 1½ inches in diameter. As one car descends the other goes up. The cars have rounded fronts, and have the seats arranged in three tiers of open "opera box" compartments, so that everybody has a clear and uninterrupted view. The car makes a trip in eight minutes, and will carry nominally 36 passengers, although 60 New Yorkers, trained in bad habits on the Elevated Road, have been known to squeeze in at once. The Incline is most substantially built, being practically terraced in the mountain side. There is some open work, however, and at one point the cars cross a trestle 200 feet long, one end of which is 100 feet higher than the other. Two of our illustrations show the modus operandi of running the cable. It will have been noted that the cars are balanced against each other, so that the call for extra lifting power is not great. The motor operates the train of gearing and the cable wheel, a feature of which is its sensitive automatic arrangement (of the Hallidie clip pulley type) for gripping the cable upon any strain above the normal, which thus prevents the cars from traveling beyond a predetermined speed. This is a quite necessary point of precaution when we remember that the average grade of the road is 59 per cent. or 11 per cent. steeper than the steepest portion of the Mt. Pilatus road in Switzerland. The clip pulley is set horizontally, and the whole mechanism is firmly anchored in solid granite. Upstairs, above the motor room, is the room in which the attendant operates the Incline, having all the control apparatus at his hand, and being in communication with the power house, etc., by means of the telephone.



PROF. T. S. C. LOWE.

At the summit of the Great Cable Incline we reach Echo Mountain House, 3,500 feet above sea level. This altitude with its lovely scenery would satisfy most people, but Prof. Lowe is pushing on to the summit of Mount Lowe, 6,000 feet high, and from the upper end of the Great Cable Incline proposes to run another trolley road connecting the Echo Mountain with an observatory, hotel, etc., at the summit of the noble peak named after him. Prof. Lowe has proposed that if a public or private subscription of $100,000 be made, in the purchase of stocks or bonds of the road, he will himself furnish the rest, for the extension of the road, and will also equip the observatory with a 37½ inch reflector, a 16 inch refractor, a 12 inch refractor and two 8 inch refractors, making a splendid outfit for astronomical work at a point where the conditions are peculiarly favorable for star study. This subscription would not need to be a donation (as was the case with the Lick Observatory), but being in the securities of the road, is considered by all competent financiers, who are familiar with its working, as a first-class investment, while at the same time furthering a worthy scientific project for the benefit of the world. We are enabled to state to our readers that if any individual will purchase this amount of securities, one of the noble peaks of the Sierra Madre range will be named after him, thus carrying his name down through all ages—a memorial more lasting and far more honorable than marble column or ostentatious tomb. It must be the wish of all who, like the present writer, know Prof. Lowe, that he may be no less successful than was Mr. James Lick in enlisting public support for such a praiseworthy scheme. Electricians will also be interested to learn that Prof. Lowe intends setting up a fine search light at the peak of Echo Mountain and that he is already in correspondence with American and European makers on the subject.

Before closing this article it should be added that there are a great many features of novelty and interest about the road beyond those already spoken of. At Rubio Pavilion, for example, the electric cars have their terminus in the hotel attic, and it might be said with truth that the roof of the hotel was built first. The means of entrance are akin to those patronized by Santa Claus, and one descends by means of the chimney—or elevator. Another curious feature is that Echo Mountain House is on one side of the mountain and its kitchen on the other, the connection being a tunnel lighted by incandescent lamps. Prof. Lowe certainly deserves congratulation on this original scheme for getting the cuisine out of range. Electric lights are also used with novel and beautiful effect in Rubio Cañon and the Thalehaha Falls; and the proprietors of Eastern mountain resorts could in more than one respect take a leaf out of Prof. Lowe's book.

We are indebted to Prof. G. Wharton James, F.R.A.S. (an accomplished lecturer, associated with Prof. Lowe in this enterprise) for much of the information contained in this article and for a fine set of photographs of the road, hotels, mountains, etc., of this wonderland of the Sierra Madre range.

ELECTRIC RAILWAY FIGURES IN ST. LOUIS.

SOME interesting figures were given out regarding the operation of the electric and cable roads of St. Louis. The National Railway Co., a Chicago corporation, capitalized at $2,200,000, controls five of the St. Louis roads, as follows: Cass Ave. and Fair Grounds (including the Northern Central and Union railways), electric, 35 miles and 70 motor cars; Citizens', 18 miles cable and 3 horse, and 172 cars in all; and the St. Louis R.R. Co.'s line operating 14⅜ miles of cable and having an equipment of 240 cars. At the annual meeting of this company held in Chicago it was announced that the net earnings for the year were $199,947 or 9.088 per cent. against 10 per cent. earned in 1892. The gross receipts of the five roads were $1,416,817, a decrease of 1.4 per cent. Operating expenses were 60.12 per cent. of gross receipts. The number of trips in 1893 was 877,302, a decrease of 16,988. The car mileage was 11,844,031, and the passengers carried 28,313,504—decreases, respectively, of 103.326 and 385,321. The gross receipts of cable lines were $1,035,455 while the gross receipts of horse and electric lines amounted to $381,372. Cable receipts decreased $50,987 while horse and electric car receipts increased $30,258. Comparing operating expenses it appears that the cable line expense was 59.4 per cent. of the income while horse and electric expense was 64 per cent. The cable mileage was 9,368,758 and of horse and electric lines 2,475,273, The cost of operating the cable per car mile was 7.32 cents or, including interest, 9.34 cents; while the corresponding figures for horse and electric lines were 11.09 and 13 11 cents. The new construction of the year which has cost $1,201,356 included 32.37 miles of new track, 33.2 miles of overhead electric construction, 70 motor cars and remodeling 131 old trailers, engines, power plant, etc. D. G. Hamilton, of Chicago, is president of the company.

PROF. BARRETT AND THE CONDUIT.

PROF. JOHN P. BARRETT, city electrician of Chicago, has declared that, according to his judgment, the Love underground trolley system, as now running in Washington, affords "a complete solution of the question of trolley electric street railroads."

MISCELLANEOUS.

THE THEORY AND DESIGN OF THE CLOSED COIL CONSTANT CURRENT DYNAMO.—III.—(*Concluded.*)

BY PROF. HENRY S. CARHART.

In the second method the overlap of the brushes must be inversely as the induction in a coil under the brush in different parts of the field, for the presence of the pole of the armature at any point reduces the induction. This point is a complicated one and needs further experimental study. But in the third class of machines the overlap of the brush is constant and the field is not weakened by cutting out coils on small load. Neither are the pole faces cut away to produce uniform induction. Attention is given to the thickness of the pole pieces so as to avoid unnecessary crowding of the lines of force toward the central portions. It is also desirable to avoid thinning the polar horns lest they become saturated.

The author then spoke of the old Sperry machines with internal pole pieces, and gave the results of some investigations made by him upon this type and also upon the old Gramme machine, from which he arrived at the conclusion that for practically sparkless commutation it is not necessary that the induction *near*, but *under* the brush shall be a constant. The effective means by which, with constant current, the brushes can be set in any plane round the commutator cylinder is the reactive effect of the armature. This fact is brought out quite clearly by plotting the integrated potential differences between the upper or positive brush and the third movable one as ordinates to a horizontal line.

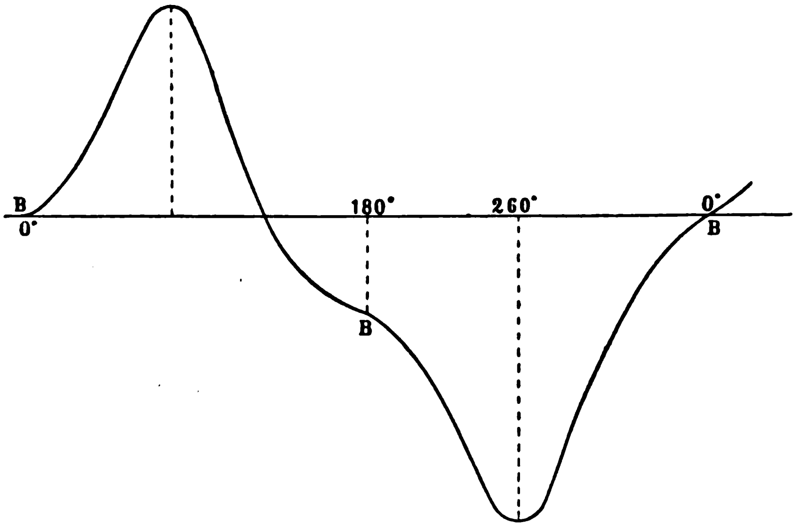


FIG. 2.

The data are the same as were employed to plot the first curve in Fig. 1.[1] If Fig. 2 is examined a decided flattening in the curve will be found at 180 degrees, the position of the negative brush. The same flattening may be seen at 0 degrees. All curves, plotted with data obtained at different loads, show the same diminution or stay of the inductive process near the poles of the armature. The armature at these points paralyzes the field. As the poles of the armature move round they sweep away the lines of force of the field, and only enough remain to produce an E. M. F. competent to offset the E. M. F. of self-induction and, in addition, cause the newly directed current to grow to its normal value as the coil passes out from under the brush.

This reactive power of the armature may be utilized to effect approximate regulation for constant current without brush-shifting. But for this purpose the load cannot be a maximum. The poles of the armature must be far enough forward to produce increase of magnetic leakage.

The conditions requisite for sparkless commutation of a constant current machine are quite clearly defined. The self-induction of the short-circuited coils must nearly balance the field in all positions of the brushes. The author then quoted Mr. Esson[2] and Prof. Ryan[3] as saying that the brushes must be kept under the pole faces in order not to enter the weakened fields between the pole corners, and stated that he did not consider this condition absolutely essential, since at maximum E. M. F. the brushes may be moved through a considerable angle without appreciable change in sparking. He dwelt upon this subject at considerable length and supported his statement by data from machines in actual operation.

In conclusion the author said: The design of closed-coil Gramme rings for high potential arc lighting has thus far been limited to the two-pole type of field-magnet. This involves the maintenance of higher speed than engineers find desirable. The conditions of present practice and the requirements for the immediate future demand a new departure in this class of dynamo design. All indications point toward a multipolar machine of about 50 kilo-watts capacity and slow speed. The armature will contain a liberal amount of iron, much larger than would be found desirable for constant potential machines. Such a dynamo is already in demand, and it will find an immediate field for the lighting of large cities.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.—VIII.

BY PROF. GEORGE FORBES.

(*Discussion.*)

Mr. Alexander Siemens said it was only right to the Commission who asked for the tenders that he should put the matter from a different point of view from that represented by Mr. Ferranti. He had not the conditions upon which the tenders were given. He (Mr. Siemens) had the pleasure at the time of speaking to the President of the Commission, who explained to him that the conditions were to be, that the different competitors were to send in detailed designs, and if successful, superintend the construction of the machinery in America for a commission of 2½ per cent. or 5 per cent., he forgot which. Under those conditions they competed, but did not send detailed designs, and as a matter of course, were excluded from the prizes. But he was perfectly certain that nobody who read the conditions under which they tendered could say that it was not from the beginning the intention to construct the whole of the machinery in America. He did not think any question ought to arise about being able to send a current of 20,000 volts through underground cables. He, for one, would be perfectly ready to supply cables that would carry 20,000 volts. Such cables were in daily use at the Frankfort Exhibition, having been supplied by his firm for connecting the transformers in the machinery hall to those in the Main annex; the normal working pressure was 20,000 volts, the cables having previously been tested to 40,000 volts. Another point which had been insisted upon was that it was quite out of the question to think that a continuous current could serve for such a transmission. Well he was not so sure about that. Their own project for the Niagara transmission was for continuous current, using machines and motors in series. He was not sure that the Cataract Construction Company would not be converted to the continuous current before they had done.

Mr. S. Evershed said one speaker had spoken of the effect when large solid conductors were used; but Prof. Forbes did not say he was going to use large solid conductors, and he (Mr. Evershed) did not doubt that he would not do so. He showed in his diagram of the subway something which might be taken to be laminated strip conductors, so that the skin effect, elaborately discussed by Lord Kelvin, would not have any prejudicial effect. But there was one effect which would come in, and it was of vastly more importance, and that was the induction between the conductors, whether solid or laminated. It was easy to work out what the back electromotive force of induction would be for any pair of conductors run at any given distance apart, and he had worked out a few cases, taking the conductors to be 6 in. apart, or 12 in. or 3 ft. He also took the density at 333 amperes per square inch, which he understood the author proposed to use. He found that there was one great argument for using a low frequency as possible, namely, the enormous inductive drop in the lines if run at the 100 periods of Mr. Mordey. If they had mains of 3 sq. in. in section, as Prof. Forbes would have, and placed those mains 6 in. apart, if they ran at 100 periods they would have an inductive E. M. F. of 880 volts per mile. Running at 25 periods this was reduced to 192 volts, while the resistance drop was 27 volts. On that ground alone Prof. Forbes appeared to him to have an unanswerable argument in favor of low frequency in that particular case. The only other point he desired to refer to was the question of coupling in parallel. He wanted, if possible, to get Prof. Forbes to tell them distinctly what were the uses of an artificial load in coupling machines in parallel.

Mr. Crompton said there had been an important omission in the discussion. The question which was of real interest to them was, What would be the cost of power to the users in Buffalo or in the more distant towns? How would it compete with the cost of power produced in those towns? That was the point that would interest him most. He should think many engineers like himself had had such schemes on a smaller scale brought before them, and in the large proportion of cases they were reluctantly obliged to abandon them because the interest on the cost of the plant was so great as to overwhelm the advantages of

using water power. He had been forestalled in many of the remarks he would have made by Mr. Ferranti. The barefaced attempt to pick the brains of the world and then to utilize the information gained for the benefit of the American manufacturers was a thing to be admired. He was sorry to say that similar attempts were often made in England; he spoke feelingly. There were many who had spent their blood and treasure in the perfecting of the mechanical details and the other details of electrical machinery, and who could not get any reward for their labors simply because no system of patent laws could cover every little detail of design. The regular modern habit was for the last comer to pick the brains of the world, so they must not blame the Americans, who were only doing on a large scale what had been done so often before on a small one. With regard to the culvert he would not like to be in that culvert when 20,000 volts were going on. If an arc started at one end of that culvert it would go right up to the other end, the whole eighteen miles, in a very short time. Prof. Forbes was going to use porcelain insulators, and he would ask him if he had made experiments to know what the insulating power of porcelain was. What was good enough for electric telegraphs was not good enough for underground work, and failures had been made by those who without sufficient trial had adopted the material used for aerial insulators for underground work. They had made great improvements, and had now got a material that carried 200 volts satisfactorily; whether they would ever get a material which would carry 20,000 volts was beyond him at present. Oil insulators were supposed to be a great remedy, but he thought there were many there who would agree with him after a long trial that they were entirely useless. He did not think continuous currents had been condemned on sufficient evidence. It was useless for people to get up in that room and say there were no difficulties in the matter of "parallelizing" alternators. Grave difficulties did exist, and although Prof. Forbes might minimize them, and probably would, by his low frequency he would find he had not then got over the great problems that would arise. He did not agree with Mr. Ferranti that 40 periods were good enough to produce good electric lighting. He had seen many of Ganz's stations at 42, and the arc lighting was disgraceful.

Mr. Weeks asked Prof. Forbes whether his circuits were equally divided on either side, with the lead on one side and the return on the other. Prof. **Forbes** declined to answer this question.

Mr. Mavor said it would be interesting if Prof. Forbes would describe the method proposed for ventilating and drying the tunnel. This was a matter of the greatest importance, as constant atmospheric conditions in such a subway were most difficult to maintain. It was notable that the most severe criticism of the scheme for carrying high-tension currents along bare conductors in a culvert came from the principal exponent of the similar method of conducting low-tension currents. The author has said in his Paper that Mr. Tesla has clearly demonstrated the rapid deterioration of solid insulations with currents of high frequency, but many of these effects are also present with currents of low frequency at an equally high voltage.

Major-Gen. **Webber** said they ought all to feel the greatest sympathy with Prof. Forbes in connection with this Paper from one point of view. He had brought before them a Paper referring to work not yet carried out, and in criticizing the account he had been good enough to favor them with they should remember that it was inevitable that modifications would have to be made in carrying out that work.

Mr. Kapp gave an abstract of a communication from Mr. C. E. L. Brown. Mr. Brown advocated a higher frequency than Prof. Forbes, and with regard to running in parallel said he had been unable to detect any difference between low frequencies such as 15 and up to 100. It was astonishing that even at the present day so much was still said of the difficulty of running alternators, single or multiphase, in parallel. He had run machines of very different types in parallel under the most different conditions, and had never found the slightest difficulty; indeed, he had come to the conclusion that the coupling of alternators in parallel was as easy as, if not easier than, that of direct machines. To adopt the two-phase system using four wires seemed to him a good arrangement, and judging from his own experience none but good results could be obtained. It certainly seemed remarkable, considering the number of designs sent in, many of which were extremely good, that Prof. Forbes should have decided upon about the worst arrangement possible for his machine. He could not imagine a more inconvenient arrangement than the magnetic wheel revolving outside the armature, so that it was impossible to get at the machine while in motion, whilst losing entirely the ventilating effect of the revolving wheel for the cooling down of the armature.

FUNNY LEGISLATION.

A member of the New York Legislature has introduced a bill requiring the insulation of all electric wires used for street railroad purposes. By last reports, he was still at liberty.

ECONOMY IN THE USE OF TRANSFORMERS.[1]

BY P. J. McFADDEN.

A transformer is nothing more than a dynamo without moving parts and is therefore no exception to the rule that it works best when loaded up to its rated capacity. In selecting a transformer for a given customer, the central station superintendent will too often install one capable of supplying the total number of lights for which the house is wired. In some cases this cannot be avoided, but in houses wired, say, for 40 to 50 lights it will seldom be necessary to put up a transformer any larger than a 30 lighter, and right here I would say that a transformer of a whole size smaller can often be used if the superintendent would take the trouble to consider the case of the particular customer in question. The neighborhood, the size of his family and their habits relative to the probability of entertainments involving the burning of nearly all the lamps in the house, would all with a moment's consideration, determine sufficiently closely what the maximum load would be.

But is it always necessary to install a transformer for every individual customer? Are not some of your stores or even in some cases your residences, so bunched that one transformer could be made to do for several; and if so would you not, if necessary, go to a little trouble with your secondary wiring to accomplish this? Even the bunching of, say, three moderately large transformers to serve four or five consumers where one or at most two are likely to have a large load at one time and where this comes so seldom as to make it expensive to put up for each of them a transformer capable of taking that load, while a step in the right direction, is seldom good practice for if the primary fuse of one should blow them out not only does the secondary of that transformer (which is now dead, as far as its capacity to give out current is concerned) become a load upon the other two, but also the load of lamps it formerly carried must now be borne by the others. When this is the case the fuses of the other two will be likely to blow and the whole arrangement disabled.

More than one case has recently come to my notice, showing how in practice the substitution of one large transformer for several smaller ones has worked to the saving in first cost to the station, and, as we know from the principle of the transformer, in the economy of operation as well.

Aside from the advantages of regulation and efficiency which are far reaching in that their effect is operating continually, there are other and quite as palpable ones that especially recommend this system. Perhaps first of all comes the saving in the first cost. This plan not only preserves to you this advantage in first cost of large transformers but also admits of your using a very much lower capacity than the aggregate of the lamps wired up. There is a greater saving in the cost of installation and in the cost of repairs. Further than this the danger from lighting in the primaries is reduced at least in proportion to the number of transformers replaced.

I have spoken until now of the use of large transformers with secondaries connected on the ordinary two wire system using, if desired and the distances are not great, 52 volt lamps; otherwise 110 volts; but why stop here? The very reason why you adopted the alternating system was on account of the saving in copper in the mains and feeders, and you did this by sending a small current to a great distance at a high voltage, knowing that it is only amperage that demands a large cross section of copper. Now why not apply this principle to the secondary wiring as well, using as high a voltage as is permissable in practice. Manifestly this can be accomplished by running the secondary wiring on the 3 wire system having a difference of potential of 220 volts between the outside wires, and using 110 volt lamps. Here again we introduce a feature that, added to those above enumerated as being present in the use of large transformers, makes the system of 3-wire secondary wiring from transformers the most efficient that modern practice is capable of. The loss in the secondary wiring is here cut down to minimum, as the current is only one fourth of what it would be with an equal number of lamps of 52 volts and for the same percentage of loss, the actual drop in volts can be doubled. As a consequence the wire for a 220 volt circuit would need to be but $\frac{5}{64}$ of that for a 50 volt circuit.

Ordinary transformers can of course be connected in pairs with their 100 volt secondaries in series and run out on 3-wire, but a still greater saving is secured in using a transformer whose secondaries are so brought out that a 3-wire service is obtained directly from the one transformer.

Opportunities for the employment of the step-up and step-down transformer plan are rare in stations in this section and I have purposely confined my remarks to the employment of large transformers on the 2-wire system, or better yet two transformers with secondaries connected in 3-wire, or still better, and best of all, one large 3-wire transformer, as applications of these can be made in the plants of each one who is using alternate current.

THE SPEED OF ELECTRIC CARS.

THE comments on electric car accidents which come under one's eyes almost daily in the popular press are not calculated to raise the spirits of the managers of street railway corporations, while the damages which are declared against the roads by juries in numerous legal actions must eventually force them to adopt some means for their own protection, independent of the demands of the public. The spirited discussion which a short time since occupied the columns of The Electrical Engineer served to bring out a number of weak points, both in the electrical and in the mechanical equipment of the car, not to speak of troubles due to the personal characteristics of the motorman himself. Most stress was and is laid on the inadequacy of the methods of braking usually employed. A closer study of the situation, however, seems to show that there is still another factor involved in the safe handling of electric cars which has not yet had that attention bestowed upon it that its importance unquestionably demands—and that is, some means for enabling the motorman to know at a glance the speed at which his car is running. The large reserve powers with which the modern electric cars are very properly equipped in order to take care of heavy loads and stiff grades, place it within the power of the motorman to run at high speeds on level stretches, and recent investigations instituted by several municipalities have emphasized this point. Thus in Brooklyn, N. Y., Prof. Geo. W. Plympton of the city Electrical Subway Commission has just filed a report made at the request of Mayor Schieren which showed that the ordinance speed of 10 miles an hour was frequently exceeded, one case being recorded in which the car ran at no lessa speed than [illegible] e r hour. In St. Louis, where a speed of 15 miles an hour is permitted in some of the wider streets of the newer sections, a speed of 30 miles per hour is said to be regularly attained. These records could without doubt be largely duplicated on closer investigation, but they will suffice to account for many of the "accidents" which are now laid at the door of the trolley car. It would be folly to suppose that any system of braking, however powerful, could be applied to prevent accidents in city thoroughfares with cars running at the speeds above shown to be common; and if they could be applied to prevent accidents *outside* of the car, some means of insuring the safety of those *inside* the car would have to be devised next. City authorities may pass ordinances regulating car speeds, without end, but it is asking too much of the motorman to calculate or even to guess at the speed of his car, in addition to his other exacting duties. What is wanted is a simple and reliable speed indicator, which will enable the motorman to tell by a glance how fast he is running. Such an indicator might be of either the visual or the audible type, or both combined, and should be arranged to give warning as soon as the maximum permissible speed is exceeded. The slow horse car, and the cable car limited to a fixed maximum speed, evidently have never required such an indicator; but that it has become a necessary adjunct for electric cars is obvious. We venture to say that its introduction will be followed by a reduction of the number of "trolley accidents," and that the cost will be but a bagatelle compared with the reduction in the amounts now paid for damages. We commend to inventors the designing of an electric car speed indicator of this class.

PATENT LITIGATION.—THE SUPREME COURT ON DIVISIONAL APPLICATIONS.

We print in other columns of this issue a late decision of the Supreme Court, which involves certain considerations as to patents issued upon divisional applications, the results of which are likely to be scarcely less important and far reaching than were those of the celebrated decision of the same tribunal a few years since relating to reissued patents. Briefly, the doctrine now laid down by the Court, as we understand it, is that only one patent can be taken for a single concrete invention, or for any part of such invention; and consequently, that when more than one patent has been issued purporting to cover different parts of the same subject-matter, all except the one bearing the lowest serial number are void. Especially is it held by the Court to be inadmissible to distribute the subject-matter of an invention between two patents, distinguishable from each other only by the different functions ascribed to a common mechanical structure.

The conclusions which have now been announced by the Supreme Court, while they will probably entail hardship upon many deserving patentees, are in our opinion, intended, by a single well-aimed blow, effectually to discourage a vicious practice which has become of late years so wide-spread and general as to constitute a notorious abuse; a remark which, by the way, may be said to apply with especial force and pertinence in connection with patents for electrical inventions. We might cite more than one instance in which a verbose and rambling specification has been filed in the Patent Office, at an early stage in the development of some particular branch of the art, containing vague references to everything under the sun which the applicant could think of as having the remotest relation to the professed subject-matter of the application. This has been kept pending in the Office for years, in order that, whenever an applicant appeared with a bona-fide invention, which appeared likely to be valuable, a divisional application could be segregated from the original mass of matter, dressed into proper shape, and put into interference with that of the newcomer. Thus a long series of divisional patents could be obtained, keeping abreast of the progressive state of the art, which, by reason of their constructively early dates, could be made to control and subordinate the work of rival, and often far more meritorious, laborers in the same field. Again, an objectionable custom has grown up among a certain class of patent-attorneys, especially some of those employed by large corporations, of filing as great a number of separate applications upon each invention placed in their hands as their practiced skill in hair-splitting could enable them to formulate; and this often, it is to be feared, with no worthier motive than the unnecessary multiplication of their own fees.

We entertain no doubt that the ultimate effect of this decision will be wholesome and salutary. As to its immediate effect there is certainly abundant room for interesting speculation. One important patent may be mentioned, which would seem to be in imminent danger of being overthrown by the new doctrine:—the famous Berliner transmitter patent, which, as was pointed out in The Electrical Engineer of January 24, 1894, in reality covers the employment, as a transmitter, of a certain mechanical structure which, in its capacity as a receiver, was patented as long ago as November 2, 1880. There are also a very large number of patents on electric railway apparatus and devices, heretofore assumed by their owners to be controlling, and upon which a considerable number of pending suits have been based, which are founded upon divisional patents. Some of these, at least, must unquestionably be obnoxious to the doctrine now laid down by the Supreme Court. This authoritative exposition of the law certainly puts a new aspect upon some important phases of the apparently interminable litigation between the rival aspirants to supremacy in the electrical industries of the United States.

A LIE OUT OF WHOLE CLOTH.

It may be truly said that the electrical community was startled by the dispatch purporting to come from Lynn, published in the *New York World*, on Monday, Jan. 29, and alleging with much detail and particularity that Prof. Elihu Thomson, backed by Mr. Pevear, was about to leave the General Electric Co. and begin all over again in opposition. We characterized the dispatch as "extraordinary," yet its place of origin and its details were such as at first to make one think there might be some little truth in it, especially after the radical changes that the General Company has seen of late. Knowing that the subject is one of deep interest to many of our readers, we hastened to bring the dispatch to the notice of Prof. Thomson, whose written statement we now have to the effect that the story is wholly without foundation.

In other words, the dispatch was a lie made out of whole cloth, and probably intended to affect the stock market. It is a great pity that the liar did not confine himself to a mere flight of fancy. Prof. Thomson's distinguished services to the cause of electrical science and invention should have preserved him from any such attempts to use his great name as a catspaw for reckless and destructive speculation. It may fairly be said of him that his interest in discoveries or inventions has been measured by their importance in increasing knowledge or in meeting some demand, and we are not aware that their prospective cash value has ever added much to the "flush of victory." The practical commercial value of an idea is of course an element of ultimate success that all great inventors must consider, if only because it furnishes the means to push forward and accomplish still more. Each discovery or invention well worked out is a conquest for mankind, and not mere "prize money" drawn from Nature. These are Prof. Thomson's sentiments, and not the low, mean ones that the dispatch so shamefully attributes to him, by insinuation.

The Fan as a Foe to Frost.

The man who adds to the number of electrical applications is fittingly regarded as a benefactor, and in the category of such worthies should be included, we think, the genius who has utilized the electric fan for driving frost out of store windows. The experiment appears to have been tried at Lewiston, Me., with great success, and the business men are said to have put in several fans for such work, as they found they could get rid of the ice in less than ten minutes. The same cure should be effective for steamy windows. There are many places where fans run for coolness in summer could also be employed as an aid to ventilation in winter.

LEGAL NOTES.

A DECISION LIKELY TO AFFECT MANY ELECTRICAL PATENTS.—THE DANGER OF DIVIDING APPLICATIONS.

SUPREME COURT OF THE UNITED STATES.

No. 145.—October Term, 1893.

W. L. MILLER AND L. W. MILLER, APPELLANTS *vs.* THE EAGLE MANUFACTURING COMPANY.

APPEAL FROM THE CIRCUIT COURT OF THE UNITED STATES FOR THE SOUTHERN DISTRICT OF IOWA. (JANUARY 8, 1894.)

MR. JUSTICE JACKSON delivered the opinion of the Court.

THE appellee as assignee of letters-patent No. 222,767, dated December 16, 1879, and No. 242,497, dated June 7, 1881, issued to Edgar A. Wright, for certain new and useful improvements in wheeled cultivators, brought this suit against the appellants, who were the defendants in the court below, for the alleged infringement thereof.

The defences made in that court were that Wright was not the first and original inventor of the improvements described in the patents; that the same were shown and described in previous devices of letters-patent, set forth in the answer; that the invention shown in each of the patents in suit is identical; that in each the supposed improvements relate to a spring and its attachments; that the function and operation of the parts are exactly the same in each; that one or both of the letters-patent in controversy were issued without authority of law, and therefore, void; that in view of the state of the art at the date of the alleged improvements of Wright, the letters patent granted to him did not exhibit any patentable invention, and for that reason are invalid; that the defendants were not engaged in the manufacture of cultivators, but have sold cultivators manufactured by P. P. Mast & Co., of Springfield, Ohio, constructed under and in accordance with various letters-patent owned by that company; that they sold the cultivators of this company without notice or reason to suppose that they were an infringement of the patents of Wright, and that they do not, in fact, infringe the same.

The class of cultivators to which the Wright patents in question relate are of the ordinary character of wheeled, straddled-row cultivators, having vertical swinging beams, or drag bars, to carry the shovels or plows, suspended from an arch or frame, mounted on two wheels, a tongue fastened to the frame and beams connected with the horizontal portions of the arch, which serves as an axle for the wheels, and surrounding the axle on each side a pipe box, to which the beam is secured, the pipe box revolving on the axle, and the beam carrying the shovels adjusted so as to swing up or down with the pipe box, according to the direction in which it is turned.

The patented device consists of a round steel rod, or wire spring, having at its fixed end a coil attached to the swinging beam, or plow bars, and extending from the coil a slightly curved arm, the outer end of which terminates in a bend or shoulder, from which the rod continues to form a short arm terminating in a sharp bend, or curl, at the free end of the spring. This spring is so adjusted that the outer, or free end thereof, bears against the underside of an adjustable grooved roller, fixed upon an outwardly extending arm upon the upright portion of the axle. This spring, with its adjustment, is intended to have a duplex action, covering the double effect, of either raising or depressing the beams carrying the shovels. The curvature of the spring is such that as it moves along the groove of the roller it presses against the latter at differents points of its periphery, and thereby the direction of its action is shifted or changed, as the position of the swinging beam is changed. Such changes in the direction of its action will assist in drawing or pulling the beam upwards in a vertical direction, giving it increased leverage as the spring is moved forward in its bearings on the roller.

In his original application, filed May 23, 1879, Wright fully described his improved device for use in connection with cultivators and claimed for it, not only its lifting and depressing action, but also its lifting power, which increased as the beams were raised.

An interference with other pending applications being anticipated as to the broad claims of the invention, the application was divided, on November 12, 1879, for the purpose of obtaining one patent for the lifting and depressing effect of the spring on the beams and another for the lifting power of the spring, increasing as the beams rise, the latter being sought upon the original application, while the former was based upon the divisional application of November 12, 1879. Patent No. 222,767, for the double effect or duplex action of the improved spring, was granted on December 16, 1879, and thereafter on June 7, 1881, patent No. 242,497, for the single effect of increased lifting force in raising the plow beams, was granted, after interference had been disposed of.

The Court below sustained the validity of both patents, and held that the defendants infringed the first, second, third, fourth and sixth claims of patent No. 222,767, and the first, second, third and fourth claims of the patents granted June 7, 1881 (No. 242,497). The complainant waiving an accounting for profits and damages, a final decree was entered, enjoining the defendants from making, using or selling to others to be used, cultivators constructed and operated in the manner, and upon the principle described in the letters-patent in controversy. From this decree the present appeal is prosecuted.

The appellants assign numerous errors, which need not separately be noticed and considered, as they are embraced in the general proposition that the court erred in holding that the patents sued on were valid, and that the cultivators sold by the defendants infringed the same. In the specification, forming part of the letters-patent 222,767, issued December 16, 1879, under the divided application filed November 12, 1879, the patentee states:

"The object of my invention is to give the operator mechanical assistance in raising and lowering the plows without interfering with their usual action and movement, to prevent the plows from rising out of the ground accidentially, and to limit their descent; and to this end the invention consists in a spring which serves the double purpose of lifting or holding down the plows at will, as may be required; in so constructing and applying a spring that it exerts a lifting action on the plow only when the latter is raised above its usual operative position; in so constructing and applying a spring that it limits the descent of the plow; also, in details of minor importance, hereinafter described.

"In carrying out my invention the one spring may be adapted to serve all or either one or more of the offices above enumerated, and may be modified in its form, construction and arrangement, as desired, provided its mode of action is retained."

[Here follow extracts from the specifications of both patents and their claims.]

It is not deemed necessary to make a separate analysis of the respective claims alleged to be infringed.

The novelty of Wright's invention consists, as held by the court below, in the application of a double acting spring to assist the operator in either lifting the plow beams, or the plows attached thereto, or in sinking them deeper in the earth, as occasion might require, while the cultivator is in service. The first patent, issued in 1879, covered both the lifting and the pressing actions or operations, while the second patent covered only the lifting effect. The spring device which was designed to accomplish these effects, or operations, is the same in both patents. The drawings in each of the patents are identical, and the specification in each is substantially the same. Under these circumstances can it be held that the second patent has any validity, or must it be treated as having been anticipated by the grant of the 1879 patent? If, upon a proper construction of the two patents—which presents a question of law to be determined by the court (Heald *vs.* Rice, 104 U. S., 749), and which does not seem to have been passed upon and decided by the court below—they should be considered as covering the same invention, then the later must be declared void, under the well-settled rule that two valid patents for the same invention cannot be granted either to the same or to a different party.

Thus in Suffolk Company vs. Hayden (3 Wall. 315) it was held that where two patents, showing the same invention or device, were issued to the same party, the later one was void, although the application for it was first filed, thereby deciding that it is the issue date and not the filing date which determines priority to patents issued to the same inventor on the same machine.

In James vs. Campbell (104 U. S., 382), the court say: "It is hardly necessary to remark that a patentee could not include in a subsequent patent any invention embraced or *described* in a prior one, granted to himself, any more than he could an invention embraced or described in a prior patent granted to a third person. Indeed, not so well; because he *might* get a patent for an invention before patented to a third person in this country, if he could show that he was the first and original inventor, and if he should have an interference declared. . . . If he was the author of *any other* invention than that which the specification describes and claims, though he might have asked to have it patented at the same time, and in the same patent, yet, if he has not done so, and afterwards desired to secure it, he is bound to make a new and distinct specification for that purpose, and make it the subject of a new and different patent." When a patentee anticipates himself, he cannot, in the nature of things, give validity to the second patent.

In Mosler Safe Company v. Mosler, (127 U. S. 355,) it was held that a patent having issued for a product, as made by a certain process, a later patent could not be granted for the process which results in the product.

In McCreary v. Pennsylvania Canal Co., (141 U. S. 467,) it was held that where a party owned two patents showing substantially the same improvement, the second was void, the court saying: "It is true that the combination of the earlier patent in this case is substantially contained in the later. If it be identical with it, or only a colorable variation from it, the second patent would be void, as a patentee cannot take two patents for the same invention."

In Underwood v. Gerber, (149 U. S. 224,) it was ruled that where a patentee obtained two patents on the same day, upon applications filed on the same day, they could not be treated as one patent with two claims, and that the complainant in suing upon the second, or the one having the latest number, could not use the first, or the one with the earlier number, to help sustain the action.

In Odiorne v. Amesbury Nail Factory, (2 Mason, 28,) the reason for the rule since established by the above cited cases was stated to be that the power to create a monopoly is exhausted by the first patent; and for the further reason that a new and later patent for the same invention would operate to extend or prolong the monopoly beyond the period allowed by law.

The result of the foregoing and other authorities is that no patent can issue for an invention actually covered by a former patent especially to the same patentee, although the terms of the claims may differ; that the second patent, although containing a broader claim, more generical in its character, than the specific claims contained in the prior patent, is also void; but that where the second patent covers matter described in the prior patent, essentially distinct and separable from the invention covered thereby, and claims made thereunder, its validity may be sustained.

In the last class of cases it must distinctly appear that the invention covered by the later patent was a separate invention distinctly different and independent from that covered by the first patent; in other words, it must be something substantially different from that comprehended in the first patent. It must consist in something more than a mere distinction of the breadth or scope of the claims of each patent. If the case comes within the first or second of the above classes, the second patent is absolutely void.

It is insisted on the part of the appellee that "whether this invention shall be protected in part of its *features* by one patent and as to the rest by another, or shall be completely protected by single patent, is a matter which concerns solely the Patent Office and the inventor." Under the rule announced in the foregoing authorities this proposition cannot be sustained.

The second and principal contention of the appellee is that the patent of 1881 covers a distinct and separate invention from the first, and in support of that proposition the appellee relies upon the rule announced in Garrett v. Seiber, (98 U. S. 77); Sewell v. Jones (91 U. S. 190,) and Merrill v. Yeomans, (94 U. S. 94.) These cases do not, however, establish the appellee's position.

In Garrett v. Seiber the arrangement for the operation of the device in the second patent was entirely different from the original patent. In Sewall v. Jones, it was held that there might be a patent for the process and one for the product. In Merrill v. Yeomans it was held that where a patent described an apparatus, a process, and a product, and the claims covered only the apparatus and the process, the law provided a remedy by surrender of the patent and a reissue for the purpose of embracing the product.

A single invention may include both the machine and the manufacture it creates, and in such cases, if the inventions are really separable, the inventor may be entitled to a monopoly of each. It is settled also that an inventor may make a new improvement on his own invention of a patentable character, for which he may obtain a separate patent, and the cases cited by the appellee come to this point, and to this point only, that a later patent may be granted where the invention is clearly distinct from and independent of, one previously patented.

It clearly appears from a comparison of the two patents and their two respective specifications and drawings, that the first function or object of the patent of 1879, relating to the lifting power of the spring, is identical with the sole object or function covered by the patent of 1881, and that the improved device and combination for the accomplishment of the lifting operation are identical in both patents.

* * * *

The first patent clearly includes the second. No substantial distinction can be drawn between the two, which have the same elements in combination and the same spring arrangement and adjustment to accomplish precisely the same lifting effect, increasing as the beams are raised from their operative positions. The matter sought to be covered by the second patent is inseparably involved in the matter embraced in the former patent, and this, under the authorities, renders the second patent void.

If the two patents in question had been granted to different parties, it admits of no question that the last would have been held an infringement of the first, for the reason that the patent of 1879 just as clearly includes as a part of the invention the increased lifting effect of the spring device, increasing as the beams are raised, as that disclosed in the patent of 1881. It certainly did not involve patentable novelty to drop or omit from the patent a claim for the depressing action of the spring arrangement which might be effected by any mere mechanical contrivance.

* * * *

This statement admits that the peculiar construction of the spring device, by means of which the lifting effect was to be accomplished, was already covered in a patent previously granted to the patentee—referring to the patent of 1879. In thus admitting the existence of a prior patented device, identical with that described in the second specification and drawings, it is difficult to understand upon what principle the patentee can be allowed to withdraw from the operation of such prior patent, one of its distinct elements, and make it the subject of a second distinct patent. It is not the result, effect, or purpose to be accomplished which constitutes invention, or entitles a party to a patent, but the mechanical means or instrumentalities by which the object sought is to be attained, but a patentee cannot so split up his invention for the purpose of securing additional results, or of extending or of prolonging the life of any or all of its elemental parts. Patents cover the means employed to effect results. (Rubber Pencil Company v. Howard, 20 Wall. 507; Fuller v. Yentzer, 94 U. S. 288.)

The prior invention covered the means and the only means, by which the results sought by the patent of 1881 were to be accomplished, and it is settled that the patentee of such prior device would be entitled to all its uses, whether described or not. (Roberts v. Royer, 91 U. S. 105; Stow v. Chicago, 104 U. S., 547.) Under these authorities a single element or function of a patented invention cannot be made the subject of a separate and subsequent patent, and it, therefore, follows that this increased lifting effect of the spring device, sought to be covered by the 1881 patent, being clearly shown and described in the specification, drawings, and claims of the 1879 patent, was not the subject-matter of a valid patent.

This conclusion is no way affected by the reservation attempted to be made in the 1879 patent of the "broad idea of a lifting spring which acts with increasing force as the beam rises," for the reason that the broad idea sought to be reserved is embodied in identically the same mechanical device constituting the invention and covered by the first patent which completely occupies all the ground that was reserved. The spring and its connecting apparatus is the same in each patent, and the claims of the first covered the double automatic action—*upward or downward.* There is nothing in the specification or claims to indicate that in the first patent the lifting action is in any degree slighter or weaker as the beam rises than in the second patent. On the contrary, both specifications clearly indicate that the spring device acts with increasing force in each patent as the beam rises.

In addition to this it distinctly appears that every claim of the 1881 patent could have been properly included and made a part of the claims of the 1879 patent. With the exception of the first broad claim of the 1881 patent, each of the other claims include the spring device with the limiting and qualifying words, "substantially as described," and by virtue of its reference to the specification, the lifting element of the spring device is shown to be the same in each patent. There is nothing in either patent or the specification or claims thereof, to indicate that there is any greater or stronger lifting action in the one than in the other. It is thus shown that one and the same mechanical device, which covers the entire invention, is described in each of the patents; and the effort to secure a second patent on one part thereof or on its function, after such part or its action had been clearly described and covered by a prior patent, cannot be sustained.

To hold under these circumstances that the first and second patents in respect to the lifting effect of the same spring device, present distinct inventions, or that both are valid for the same invention, would involve the drawing of distinctions too refined for the practical administration of the patent law.

* * * *

[Here follows a discussion of the patents to other inventors as related to the construction of Wright's 1879 patent, in view of the state of the art.]

Our conclusion on the whole case is that the patent of 1881 is anticipated by that of 1879; that the first claim thereof is anticipated by the Brown patent; that the patent of 1879, in view of the state of the art, is to be limited and restricted, if it has any validity at all, to the specific spring therein described; and, as thus restricted, it is clearly not infringed.

We are, therefore, of opinion that the decree of the court below should be reversed, and the cause remanded, with directions to dismiss the bill; and it is accordingly so ordered.

THE UNION PACIFIC WIRES—W. U. MAY OPERATE THEM.

At St. Louis, on Jan. 30, Judges Caldwell, Thayer and Sanborn, sitting in the United States Court of Appeals, reviewed the case of the Union Pacific Railroad Company and the Western Union Telegraph Company, appellants, against the United States, appellee. It came up on an appeal from the Circuit Court of the United States for the district of Omaha. Judge Thayer reversed the decision of the Omaha Court and ordered an amended decree. The decision winds up an important piece of litigation. The case involved an alleged infringement of the Pacific Railroad Acts by the Union Pacific Railroad, as, being bound to build and operate by its own servants and agents a line of telegraph for commercial and government purposes between Omaha and Ogden, it had leased its wires, poles, etc., to the Atlantic and Pacific Telegraph Company on July 1, 1881, surrended its franchise and alienated its powers under its charter to the Western Union Telegraph Company. The prayer of the bill was for a decree annulling the contracts between the road and the telegraph company and ordering the road to operate the telegraph lines itself in accordance with law. The Circuit Court granted the prayer. Judge Thayer holds that Congress could not grant to the railway a telegraphic franchise and so limit the power to exercise or deal with it as to make it a burden.

INCANDESCENT LAMP LITIGATION.

USERS ENJOINED IN PHILADELPHIA.

Opinion of Judge Acheson, in the three cases of Edison Electric Light Co. [General Electric Co.] and The Edison Electric Light Co., of Philadelphia, against (1) The Philadelphia Trust, Safe Deposit and Insurance Co.; (2) The Manufacturers' Club of Philadelphia: and (3) The Spreckels Sugar Refining Co.; U. S. Circuit Court for the Eastern District of Pennsylvania, January 25, 1894.

Subjoined is the text of the decision of which note was made in these columns last week :—

ACHESON, Cir. J. :

The patent in suit No. 223,898, granted on January 27, 1880, to Thomas A. Edison, after protracted litigation and a most vigorous defense, was sustained by the Circuit Court of the United States for the Southern District of New York and by the Circuit Court of Appeals for the Second Circuit. (Edison Electric Light Company vs. The United States Electric Lighting Company, 47 Fed. Rep., 454; 52 Fed. Rep., 300; Edison Electric Light Company *et al.* vs. The Sawyer-Man Electric Company 53 Fed. Rep.. 592.) The uncontradicted proofs in the several cases now before me show infringing use by the defendants respectively, and it is conceded that the plaintiffs—Edison Electric Light Company and its exclusive licensee in the City of Philadelphia, The Edison Electric Light Company of Philadelphia—are entitled to a preliminary injunction in each of these three suits. The Court, however, is asked to exempt from the operation of the injunction certain lamps (confessedly within the second claim of the patent) which were manufactured by the Columbia Incandescent Lamp Company, a corporation of the State of Missouri, for the reason that, in a suit brought against that company by the Edison Electric Light Company and the Edison General Electric Company in the Circuit Court of the United States for the Eastern District of Missouri after the decisions in the Second Circuit, Judge HALLETT refused a motion for a preliminary injunction upon the defendants giving bond in the penal sum of twenty thousand dollars, condition for the payment of any sums which might be decreed in that suit in favor of the complainants therein. (56 Fed. Rep., 496). The ground for this refusal was a defense then set up, which had not been made in the Circuit Court, that the incandescent electric lamp for which Edison was granted the patent was only the prior invention of one Henry Goebel. But in the earlier case of the *Edison Electric Light Co. vs. Beacon Vacuum Pump and Electrical Company*, 54 Fed. Rep., 678, that defense was interposed to a motion for a preliminary injunction, and was very carefully investigated by Judge COLT, who found and decided that Goebel's story of his invention in itself was so improbable, and the evidence to sustain the alleged anticipation was of such doubtful character that the consideration of this defence ought to be postponed until final hearing, and that in the meantime the plaintiff was entitled to enjoy the fruits of the decree sustaining the patent. Accordingly, Judge COLT granted a preliminary injunction.

In the more recent case of the Edison Electric Light Company vs. Electric Manufacturing Company, 57 Fed. Rep., 616, in the Circuit Court of the United States for the Eastern District of Wisconsin, Judge SEAMAN expressed views similar to those of Judge COLT, and awarded a preliminary injunction to restrain infringement of this patent.

No evidence whatever in support of the Goebel defense has been submitted to me, so that I am without means of forming an independent opinion as to whether it rests upon a substantial basis. Under all the circumstances, then, to give to Judge HALLETT's refusal to grant an injunction the effect here claimed for it would be to carry the principle of judicial comity to a most extravagant length. The Edison Electric Light Company of Philadelphia, vitally interested here, is not a party to the Missouri suit. But aside from that consideration, the owner of a patent undoubtedly may maintain suits for infringement against the manufacturers and users of the patented device simultaneously. (Birdsell vs. Shalliott, 112 U. S., 485; Kelley vs. Ypsilanti Dress Stay Manufacturing Company, 44 Fed. Rep., 19). True, pending a test suit against a manufacturer involving the validity of a patent in which a preliminary injunction against him has been decreed, Courts in other jurisdictions have declined to enjoin preliminarily the users of the device. But the Edison Patent has been sustained under circumstances which entitle the adjudication to high regard. It is the accepted doctrine that the decision of the Supreme Court, after exhaustive litigation upon the merits sustaining a patent, will ordinarily be regarded as conclusive on a motion for a preliminary injunction, the presumption against the existence of any valid defense against the patent prevailing at that stage of the case. (Purifier Co. vs. Christian, 3 Bann & Ad., 42, 51; Am. Bell Tel. Co. vs. Southern Tel. Co., 34 Fed. Rep., 795; American Bell Tel. Co. vs. McKeesport Tel. Co., 57 Fed. Rep., 661). I think the same effect ought here to be accorded to the decision of the United States Circuit Court of Appeals for the Second Circuit, sustaining the Edison Patent.

In each of these cases a preliminary injunction in the form prescribed by the Courts of the Second Circuit will be allowed.

THE NOVAK CASE ON APPEAL.

THE Novak lamp case, which was heard at Hartford, Conn., before Judge Shipman, came up on appeal before the Circuit Court of Appeals at New York, on Jan. 30, before Judges Wallace and Lacombe.

The Waring Company was represented by Messrs. Simonds and Morse and the Edison Electric Light Co. (The General Electric Co.) by Messrs. Fish and Dyer. The arguments, which occupied three hours, traversed much the same ground as that covered in the case before Judge Shipman. At their conclusion the Court took the papers for further consideration and decision.

ELECTRIC MOTORS EXEMPT FROM TAXATION.

The Judges of the Appeal Tax Court of Baltimore in accordance with an opinion of a city law officer, have decided not to tax electricity as a motive power. The court previously decided to levy an assessment on all machinery moved by electricity. This would have affected all business houses in Baltimore using electricity and it was regarded as a discrimination. The court will now exempt electrical machines and tax only the plants of the electric companies, as was intended by the law.

EDISON E. L. CO. vs. MATHER ELECTRIC CO.—MOTION FOR TIME GRANTED.

On motion of the defendants in the case of the Edison Electric Light Company against the Mather Electric Company of Manchester, this State, Judge Shipman in the United States Circuit Court has granted a continuance of time to the defendant to file an answer in suit. Charles E. Perkins, counsel for the defendants, argued for the motion and Albert H. Walker, counsel for the plaintiff, against it. The suit is brought on the ground that the defendants are infringing the compound winding method patented by Edison. Judge Shipman allowed the motion and gave the defendants until the first Monday in March to file their answer.

A DECISION THAT THE W. U. IS A COMMON CARRIER UNDER THE INTERSTATE COMMERCE LAW.

An important decision was handed down last week by Judge Smith, of the Court of Appeals at Kansas City, Mo. This decision affirms that a telegraph company is as much a common carrier as a railroad or express company and that as such when it carries on an interstate business it is subject to the control of the Interstate Commerce Commission. The suit was an ordinary one brought against the Western Union Telegraph Company to enforce a statutory penalty of $200 for failure to properly transmit a telegram. As a number of constitutional questions arose in the conduct of the case, it was carried to the Missouri Supreme Court for settlement.

UNDERGROUND RAILWAY WIRES IN KENTUCKY.

A BILL has been introduced in the Kentucky Legislature providing that in all cities of the State all electric street railways shall be compelled to put their wires underground. No penalty is attached for failure to obey the law, but it is provided that upon failure or refusal to comply the city authorities may take the work in hand, and have it done at the expense of the corporation owning or operating the railway. Any city may inforce the provisions of the law by mandamus proceedings.

"RECORDS FOR THE BENEFIT OF PRINTERS."

THE record in the case of The Consolidated Electric Light Company versus the McKeesport Light Company, involving the great contest being waged between the leading electric light corporations of the United States, comprises three large volumes, and its printing cost $7,000. This includes the cost of engraving, there being a great number of illustrations in the work.

CHEAP SERVICE IN TRURO, N. S.

THERE is war in Truro over telephone affairs. The Chambers Electric Light and Power Company are installing a system of telephone worked free of charge. The company undertakes to light a house throughout by electricity, put in and work a telephone and provide an instantaneous fire alarm, all for the sum of $25 per year, the price asked for telephone connection alone by the Telephone Company. Naturally the latter company objects, and a strong rivalry exists.

SOCIETY AND CLUB NOTES.

FOURTH ANNUAL BALL OF THE MASSACHUSETTS ELECTRICAL ENGINEERS AND MECHANICS ASSOCIATION.

The above ball was held in Copley Hall, Boston, on the evening of Monday, January 29th, and in spite of the inclemency of the weather was a huge success in every way. As usual the electric lighting decorations formed a most important feature, and the committee in charge fairly excelled all previous efforts in this direction. Outside, illuminating the street leading to the hall for a distance of about 300 yards, arc lights had been suspended, with crimson shades, throwing a warm red glow on the masses of snow, and looking very comfortable and cheering in the frightful storm that prevailed. Inside, the magnitude of the illumination almost beggars description. Some 3000 incandescent lights were used. At the top of the hall was a ball seven feet in diameter, studded with incandescent lights of 16-candle power each, with globes colored red, white and blue. This ball was kept slowly revolving by means of an electric motor, and a commutator on its axis switched the current first into the red bulbs, then the white, and finally the blue, producing an effect of great beauty. Streamers of incandescent lights extended from the ball to the sides of the hall. These streamers changed colors in unison with the ball. At the rear of the hall were two immense towers from floor to ceiling, each carrying about 350 lights. The lights on these towers were on six different circuits, and as the lamps were of different colors, a beautiful variation of effect was produced at will. The whole lighting was controlled by a switchboard at the back of the orchestra, which was eagerly examined by those present.

On the side walls were two large signs, built of incandescent bulbs, one reading "Welcome to Our 4th" and the other "M. E. E. and M. A., 1890–1894." The current could be sent through either the red or the white globes, as the operator at the switchboard dictated. He kept the dancers entertained in rare fashion. First the hall would be plunged in blue, then in red and white, or in a mixture of all the above colors and green. Scattered around the hall were half a dozen unique displays, also under the control of the switchboard. Two big stars, a sign "Edison," and the monogram, "G. E. Co.," meaning General Electric Company, were prominent. Flags, banners and streamers were used to fill up the bare spaces on the walls and set off the electric lights.

All the decorations were installed by members of the Association, and they are to be congratulated on the beautiful effects produced. About 2,000 people were present and a large sum was netted for the funds of the Association which is in a most flourishing condition. Much credit is due to the members of the different committees who have worked hard to make the ball a success, and they have every reason to be well pleased with the success of their labors. The committee on the ball was composed of the following gentlemen: James E. Cole, Harry Cottle, Joseph L. Winn, J. A. Collicott, and Walter J. Burke.

DR. WHEELER ON DYNAMOS & MOTORS.

A most interesting and instructive lecture in the Electrical Workers' University Extension Course was delivered on January 29, by Dr. S. S. Wheeler, whose subject was "Direct Current Dynamos and Motors." It was well illustrated by apparatus in operation, including some of the combination motor-tools to which the lecturer has himself devoted so much time and ingenuity. All the principles and features of direct current generation and motive power were taken up in brief, succinct review, and the audience gathered an immense amount of helpful information in a very short time.

CHICAGO ELECTRICAL ASSOCIATION.

The officers of this society for the present year are: President, Albert Scheible; Vice Pres't, W. D. Ray; Secretary, H. G. Dimick (227 South Clinton St.); Treasurer, F. S. Hickok; Librarian, E. F. Norton (Room 15 City Hall). At the last meeting Mr. W. Clyde Jones read a carefully prepared paper on "The Development of the Telephone."

N. E. L. A.

SECRETARY G. F. PORTER has addressed a circular letter to over 500 electric street railway companies, calling their attention to the fact that several of the topics to be taken up at the Washington meeting this month are of interest to them and should lead them to be represented.

MR. NEWTON L. SCHLOSS, who is well-known in electrical circles in New York, delivered a lecture on The Phonograph on Jan. 23, before America Lodge of the Independant Order B'nai B'rith. The meeting was largely attended and the talk proved very interesting to the members.

MONTREAL ELECTRIC CLUB.—At the annual meeting held on Jan. 15th, the reports for the past year of the secretary and treasurer showed the club to be in a flourishing condition; there being a large increase in the membership and a considerable balance in the treasury. The election of officers for the ensuing year resulted as follows: President, W. B. Shaw; vice-president, H. Ritchie; secretary, Jas. Burnett; treasurer, L. M. Pinolet; committee of management, H. Brown, Jas. Douglas and Howard D. Black.

NIAGARA AT WORK.

THE NIAGARA FALLS PAPER COMPANY, the first to make use of the newly developed water power of the falls, commenced operations at eleven o'clock on the morning of January 25, everything worked smoothly and to the utmost satisfaction of the officers who witnessed the start. The wheel house of the paper mill is of brick, iron and slate, built over the wheel pit 20 by 40 feet in section, and 155 feet deep. The pit is cut through the solid rock and lined with massive masonry to the level of the ground. Water is led from the river through a canal 240 feet long protected by three iron gratings and three sets of gates. The penstocks are 13 feet in diameter and the turbines are of 3,300 h. p. each. At present only one is in position, but another will be added later. At the top of the vertical shaft is a horizontal bevel gear meshing with three vertical gears, two of which turn the pulp grinders while the third is connected to the line shafting. From the bottom of the wheel pit a tunnel connects with that of the Niagara Falls Power Company.

The Niagara Falls Paper Company was organized about five years ago and its output will be about three car loads daily.

MR. F. S. TERRY.

THE office of secretary of the Sunbeam Lamp Mfg. Co., Chicago, has been accepted by Mr. F. S. Terry, who will now give his entire attention to pushing the sales of that company. Mr. Terry's connection with the Ansonia Electric Co. has now entirely ceased, and the branch in Chicago will go out of existence as such. It may not be generally known that Mr. Terry's relationship with the Ansonia Electric Co., or as it was formerly called, the Electrical Supply Co., had endured continuously from the Company's organization in 1885, when he and it practically began business life together. He was its first office employee, attending at that time to all the correspondence, bookkeeping and all other office work. In the winter of 1884–5, Mr. Terry went to Chicago to open the western branch, and he saw and promoted its remarkable development down to the end of his fourteen years of vigilent, unremitting service. A host of friends will desire for him renewed prosperity under the change of conditions and with the return of commercial affairs to their normal volume and activity.

MR. J. F. KELLY.

THE NATIONAL ELECTRIC CO. of Eau Claire, Wis., will now be represented in this part of the country by Mr. J. F. Kelly, who becomes its General Eastern Agent. He has opened offices at 906 Temple Court, 5-9 Beekman street, New York, and will be glad to receive correspondence and inquiries there. Mr. Kelly has a very wide circle of acquaintance in electrical engineering and trade circles. He was at one time connected with the old Electrical Supply Co. in this city, and afterwards represented the wire department of the Edison Machine Works. His services were transferred later on to the Edison General Co. and the General Electric Co.

EDISON ELECTRIC LIGHT COMPANY EARNINGS IN PHILADELPHIA.

THE annual report of the Edison Electric Light Company of Philadelphia shows that the company have paid out in dividends during 1893, $152,244 in four separate payments of two per cent. each, and one extra payment of two per cent. The surplus earnings of the year were $48,398 83, and the profits of 1893 were $200,642.83. The cost of extensions last year was nearly $297,000. Of this $238,000 was expended on work which will require about $82.000 for its completion.

The reduction of the price of gas to $1 per 1,000 cubic feet, the Board stated, has not and will not likely affect the increasing demand for current. The assets are given at $1,740,825.01.

The present directors have been re-elected without opposition, as follows: William D. Marks, Samuel B. Huey, Charles M. Swain, Amos R. Little, John Lucas, H. Blake Tyler, D. S. Lindsay, L. D. Brown, Arthur Colburn, William T. Tiers and C. A. Coffin.

AMERICAN BELL CAPITAL TO BE $50,000,000.

THE AMERICAN BELL TELEPHONE CO. have filed an application at the Massachusetts State House for permission to increase their capital $30,000,000, making the total capitalization $50,000,000. The money is needed for new work and extensions of various kinds, and some of it may be used for the further absorption of sub-companies.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 16, 1894.

Accumulators :—

Process of Making Secondary Battery Plates, W. L. Silvey, Dayton, O., 512,757. Filed Sept. 12, 1892.

The process consists in immersing anodes of lead or lead alloy and cathodes of lead in a solution of ammonia and an acid, then disintergrating the anodes by the aid of an electric current and electrically depositing the parts thus decomposed in holes in the cathodes.

Secondary Battery, A. Hough, San Francisco, Cal., 512,823. Filed Sept. 14, 1893.

The active material consists of a mixture of mon-oxide of lead, sulphate of ammonia and sulphate of magnesia, the sulphate of ammonia being decomposed and the sulphate of magnesia dissolved.

Alarms and Signals :—

Railroad Signal, C. Selden, Baltimore, Md., 512,754. Filed Feb. 1, 1893.

An electric system of block signals for steam railways.

Distribution :—

Continuous Electric Current Distributing System, M. Von Dolivo-Dobrowolsky, Berlin, Germany, 513,006. Filed Nov. 24, 1893.

Claim 1 follows :—

In a system for distributing electricity two series connected groups of consuming apparatus fed by two main conductors and a compensating conductor and a continuous current dynamo connected with the mains and a coil of high self-induction connected at both ends with diametrically opposed points of the armature winding of said dynamo, and in its centre with the said compensating conductor.

Dynamos and Motors :—

Motor Generator, J. C. Henry, Westfield, N. J., 512,890. Filed Apl. 29. 1892.

Claim 1 follows : –

In a magneto-electric machine the combination of suitable field magnets, two armatures carried by a single shaft and a single support for said shaft, between the armatures.

Ceiling Fan Motor, W. Hochhausen, Brooklyn, N. Y., 512,821. Filed Sept. 4, 1891.

Dynamo Electric Machine or Motor, H. S. Rodgers, Hartford, Conn., 512,543. Filed Jan. 31, 1893.

Claim 1 follows :

A dynamo electric machine or motor having its field-magnet cores provided with pole tips or horns lying within the planes bounding the external surface of the cores, whereby the field-magnet coils may be put in position or removed without removal of the cores.

Commutator and Connector for Dynamos, G. Wilkes, Detroit, Mich., 512,858. Filed October 2, 1893.

Provides a construction and connection of the armature and commutator of a multipolar machine that will provide only two paths for the current in the armature conductors ; and also establish a ratio of two to one between the number of segments in the commutator and the number of slots and coils.

Automatic Regulator for Dynamo Electric Machines, E. A. Sperry, Cleveland, O., and G. E. Mills, Ravenswood, Ill., 513,068. Filed April 25, 1892.

Consists of mechanism for automatically rotating the field magnet of a dynamo to regulate the current generator.

Galvanic and Thermo-Electric Batteries :—

Excitant for Voltaic Cells, G. Hewett, New York, 512,069. Filed April 3, 1893. Consists of sulphuric acid and sulphate of soda prepared in a dry state.

Heating :—

Electric Heater, W. J. Bowen, Norwalk, Ohio, 512,797. Filed Apl. 14, 1893.

The heating conductor is so arranged as to impart its heat to a series of tubes into one end of which cold air is forced which is heated by its passage through the tubes.

Lamps and Appurtenances :—

Electric Arc Lamp, C. J. Hartley, Decatur, Ill., 512,880. Filed Mch. 31, 1893.

Provides means for increasing or diminishing the effect of the derived circuit in the carbon carrying core.

Electric Search Light, C. E. Ongley, New York, 513,052. Filed Aug. 22, 1893.

Relates especially to means for flashing the light for signal purposes.

Metallurgical :—

Process of Manufacturing Aluminum, W. E. Case, Auburn, N. Y., 512,801. Filed March 13, 1893.

The process consists in combining aluminum sulphate and calcium fluoride to form an aluminum fluorsulphate solution, adding thereto a caustic alkali, and then removing, fusing and electrolyzing the precipitate.

Process of Manufacturing Aluminum, W. E. Case, Auburn, N. Y., 512,802. Filed Mch. 13, 1893.

Similar to No. 512,801.

Miscellaneous :—

Electric Washing Machine, J. P. Johanson, New York, 512,970. Filed May 9, 1893.

Apparatus for Electrically Treating Raw Hides, P. R. De F. D'Humy. Chicago, Ill., 512,706 Filed Feb. 4, 1893.

Electric Inhaler, R. L. Larcom, Fandon, Ill., 512,723. Filed Sept. 29, 1893.

Machine for Winding Electro-Magnets, R. Varley, Jr., Englewood, N. J., 512,769. Filed Apr. 13, 1893.

Railways and Appliances :—

Rail Bond Connector for Electric Railways, H. R. Keithley, Chicago, Ill., 512,711. Filed Feb. 27, 1893.

Has thimble shaped terminals adapted to be expanded after being placed within the holes in the rails.

Trolley-Wire Insulator, H. H. Luscomb, Hartford, Conn., 512,888. Filed Oct. 18, 1893.

Relates to certain details in the construction of trolley wire hangers.

Battery System for Electric Railways, L. B. Rowley, Ashland, Wis., 512,907. Filed Feb. 15. 1893.

Consists of a main circuit including in multiple arc two or more independent sets of batteries, a working circuit and means for automatically switching the set of batteries bodily and individually from one circuit to the other.

Electric Railway Trolley, W. Van Benthuysen, New Orleans, La., 512,923. Filed March 24. 1893.

Claim 2 follows :

A trolley wheel, made in the form of a cone, with a concave flange of smaller diameter than the cone formed on its smaller end.

Electric Railway Trolley, G. W. Mackenzie, Beaver, Pa., 513,028. Filed, April 5, 1893.

Has, instead of the trolley wheel, two independent vertical, conical rollers between which the trolley wire passes.

Switches and Cut-Outs :—

Electric Switch, E. P Warner, Chicago, Ill., 512,774. Filed Dec. 1, 1891.

Consists of two pairs of slit contact plates, one connected to each of the terminals, and a switching block sliding between the two members of one pair so as to bridge the space separating the opposed ends of the pairs and making contact with the second pair of plates.

Automatic Electro Magnetic Switch, H. P. White, Philadelphia, Pa., 513,065. Filed Sept. 25, 1893.

Telegraphs :—

Sextuplex Telegraph, T. A. Edison, Menlo Park, New Jersey, 512,872. Filed June 2, 1877.

Employs differential relay magnets in the respective circuits in combination with shunt connections around the relay magnet and condensers of nearly equal electrostatic capacity in the respective shunts.

Telephones and Apparatus :—

Switchboard, W. A. Childs, Englewood, N. J., 512,805. Filed Oct. 25, 1893.

Has for its object to provide means for readily removing the entire cord, plug and weight from a telephone switchboard, should it become faulty, and inserting another in its place.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 23, 1894.

Accumulators :—

Secondary Battery, E. & L. Paget, New York, 513,245. Filed Feb. 9, 1893.

The electrodes are treated in a heated solution of a metallic nitrate yielding an oxide of the metal that is insoluble in water.

Alarms and Signals :—

Electric Bell, C. Turnbull, Jr., North Shields, England, 513,219. Filed July 24, 1893.

Has especially for its object the regulation and adjustment of the stroke.

Electric Bell, C. Turnbull, Jr., North Shields, England, 513,220. Filed Nov. 11, 1893.

Similar in its object to No. 513,219

Electro Mechanical Gong, N. H. Suren, New York, 513,251. Filed Oct. 11, 1893.

Electric Call-Bell for Pneumatic Tubes, L. Strouse, Baltimore, Md., 513,345. Filed April 6, 1893.

Annunciator System, A. L. Vogt, Delaware, Ohio, 513,352. Filed March 8, 1893.

A device for expediting communication between physicians and their patients.

Railway Signaling Apparatus, E. A. Winterhalder, Kappel, Germany, 513,376. Filed Dec. 3, 1892.

An electric block system for single track steam railways.

Distribution :—

Means for Neutralizing Self Induction in Alternating Currents, E. Thomson and E. W. Rice, Jr., Swampscott, Mass., 513,349. Filed Sept. 1, 1893.

Employs a condenser connected inductively with the circuit through a transformer of such a ratio of transformation that the potential in the condenser circuit is greater that that in the working circuit of the magnet.

Method of and Apparatus for Preventing Phase Displacement in Alternating Circuits, C. P. Steinmetz, Lynn, Mass., 513,370. Filed Sept. 9, 1893.

Employs condensers or equivalent neutralizers of self induction and provides for the ready regulation of the action of such condensers in accordance with the changes of load.

Dynamos and Motors :—

Electric Elevator, N. P. Otis, Yonkers, N. Y., 513,134. Filed June 25, 1890.

Electric Motor Controlling Device, J. E. Stanton, Boston, Mass, 513,213. Filed June 19, 1893.

A controller adapted especially to surgical and dental motors.

Magneto Electric Machine, H. H. Taylor, Los Angeles, Cal., 513,347. Filed Mch. 15, 1893.

Relates especially to certain details of construction to reduce the amount of idle wire in the armature, to reduce air friction between the armature and poles and to facilitate repair.

Dynamo Electric Machine, G. F. Dieckmann, Chicago, Ill., 513,459. Filed Dec. 28, 1892.

Claim 1 follows :

In electric machines, the combination with the field magnet and with its armature helix of a supplemental coil mounted separately from, but located parallel to, said helix and inductively influenced thereby.

Commutatar for Dynamo Electric Machines, H. L. Fee, New Orleans, La., 513,460. Filed July 26, 1893.

Claim :

The combination with the radial arms of a commutator, of the detachable insulating thimbles which are applied to the free ends of said arms and surround the same.

Heating :—

Electric Radiator, W. D. Hough and E. Z. Burns, Niagara Falls N. Y., 513,109. Filed Jan. 9, 1893.

A radiator in which a current is passed through pipes containing a circulating liquid forming a resistance and heat developer.

Lamps and Appurtenances :—

Electric Arc Lamp, W. Jandus, Cleveland, O., 513,111. Filed Oct. 23, 1893.

Claim 1 follows :

In an electric arc lamp, an arc-inclosing chamber closed air-tight at its top and sides, and closed,—but not air-tight,—at its bottom, to allow limited inlet to and free outlet from the chamber.

Electric Light Fixture for Music Stands, W. J. Kelly, Boston, Mass., 513,113. Filed Sept. 19, 1893.

Measurement :—

Electric Meter, J. C. Henry, Westfield, N. J., 513,264. Filed Dec. 21, 1891.

An indicator and register showing the amount of energy being absorbed at the instant of observation and also measuring the total amount consumed during a given time.

Electric Meter, C. Gudgell, Independence, Mo., 513,391. Filed June 21, 1893.

A meter for indicating the rate of consumption of lighting or power currents and also the total amount of current consumed during any given time, actuated by clock work mechanism with an automatic rewinding attachment.

Metal Working :—

Process of and Apparatus for Melting Metals by Means of Electricity, A. F. W. Kreinsen, Hamburg, Germ., 513,270. Filed Sept. 28, 1893.

Consists of an electrode composed of the metal to be melted and a carbon electrode; both located within the cap of the crucible.

Process of Precipitating Metal Sulphide from Hyposulphite Solutions, H. Hirsching, Salt Lake City, Utah, 513,324. Filed May 6, 1893.

The process consists in subjecting the solution to the action of an electric current.

Miscellaneous :—

Phonograph, T. A. Edison, Llewellyn Park, N. J., 513,097. Filed December 8, 1890.

Gas and Electric Coupling, W. J. Kelly, Boston, Mass., 513,112. Filed Sept. 19, 1893.

A combination gas pipe and electric wire coupling for chandeliers, etc.

Automatic Electric Stop Motion for Knitting Machines, J. Buchel, New Orleans, La., 513,259. Filed Mch. 18, 1893.

Electrical Apparatus for Firing Submarine Mines, G. Bertolini, Venice, Italy, 513,294. Filed April 6, 1892.

Electric Gas Lighter, W. L. Brown, San Francisco, Cal., 513,300. Filed June 22, 1893.

Electric Belt, W. C. Fuller, Salina, Kansas, 513,387. Filed Oct. 11, 1893.

Method of Cooling the Iron of Transformers, H. A. Rowland, Baltimore, Md., 513,420. Filed Feb. 8, 1893.

Employs a current of liquid circulating in juxtaposition to the laminated iron sheet and parallel to the motion of the lines of force.

Method of Cooling Transformers, H. A. Rowland, Baltimore, Md., 513,421. Filed Feb. 8, 1893.

The transformer is surrounded by a volatile liquid which, by boiling, carries away the heat.

Means for Cooling Electric Conductors, H. A. Rowland, Baltimore, Md., 513,422. Filed Feb. 14, 1893.

Claim 1 follows :

The method of cooling hollow conductors carrying electric currents, which consists in passing a conducting fluid through said conductors, and in breaking the electrical continuity of said fluid after it leaves said conductor.

Self-Induction Coil, C. F. Scott, Pittsburgh, Pa., 513,425. Filed Nov. 25, 1892.

The invention provides a laminated core which shall permit the passage of a minimum current at normal voltage, but shall offer as small a resistance to the current as possible when the difference of potential rises beyond a given point.

Resistance Coil, H. P. Davis, Pittsburgh, Pa., 513,457. Filed April 22, 1893.

Electric Clock System, J. H. Gerry and F. M. Schmidt, Brooklyn, N. Y., 513,469. Filed May 16, 1893.

Railways and Appliances :—

Electric Motor for Street Cars, B. G. Lamme, Pittsburgh, Pa., 513,401. Filed Mch. 27, 1893.

Claim 1 follows :

In a motor for electric cars, an armature mounted upon the axle of the car, and two field magnets independently sleeved upon the axle and suspended at their rear ends from the car body.

Span Wire for Overhead Electric Railways, S. H. Short, Cleveland, Ohio, 513,426. Filed April 1, 1890.

The invention consists in dividing the span wire into insulated sections where more than one trolley wire is carried on a single span wire.

Supply System for Electric Railways, H. S. Pruyn, Hoosick Falls, N. Y., 513,440. Filed Sept. 16, 1893.

The invention relates to special construction of conduit systems in which main and secondary conductors are used.

Electrical Means for Propelling Canal Boats, J. Sachs, New York, 513,466. Filed Feb. 15, 1893.

Employs an electric motor running on an elevated track along the banks of the canal.

Switches and Cut-Outs :—

Electric Safety Device for Elevators, R. W. Magrane, Brooklyn, N. Y., 513,122. Filed Mch. 17, 1892.

A switch actuated by the elevator doors having for its object to prevent the movement of the elevator in either direction unless all the doors are closed.

Rheostat, W. Meredith, Aurora, Ill., 513,126. Filed Apl. 20, 1892.

Electric Light Cut-Off, J. B. Stewart, Haverstraw, N. Y., 513,250. Filed June 21, 1893.

Comprises a single magnet, a single armature, a rocking arm mounted on the magnet and provided with a conducting and a non-conducting bar and carrying the electric light terminals.

Automatic Rheostat, B. C. Van Emon, San Francisco, Cal., 513,350. Filed Apl. 4, 1893.

Telephones and Apparatus :—

Microphone, A. Groper, Dusseldorf, Germany, 513,181. Filed Jan. 14, 1893.

Employs a mica diaphragm and a carbon diaphragm with an air space between them and a number of carbon balls normally in contact with the carbon diaphragm.

Telephone Transmitter, F. R. Colvin, New York, N. Y., 513,305. Filed Oct. 10, 1893.

Claim 1 follows :—

A telephone transmitter provided with a diaphragm loosely supported and having its entire rim or outer edge free to vibrate undampened, said diaphragm carrying electrodes fixed with relation to each other, and a resistance varying material between the electrodes.

Apparatus for Registering Telephone Calls, L. Kahn, Hamburg, Germany, 513 364. Filed Mch. 2, 1893.

Relates to a transmitter for producing currents of alternating polarity to operate a printing telegraph at a distant station from the call station, designed to register the number of the latter in the event of the call signal not being heard.

HERTZ'S "ELECTRIC WAVES."

An excellent English translation by Mr. D. E. Jones, with a suggestive preface by Lord Kelvin, has been published by McMillan & Co. It is well got up, and is issued at $2.50. Copies will be furnished from THE ELECTRICAL ENGINEER office, postage free, on receipt of price.

DEATH OF MRS. ALFRED VAIL.

The death is announced of Mrs. Alfred Vail, whose husband is known to fame as Morse's right hand in the invention and development of his electromagnetic telegraph.

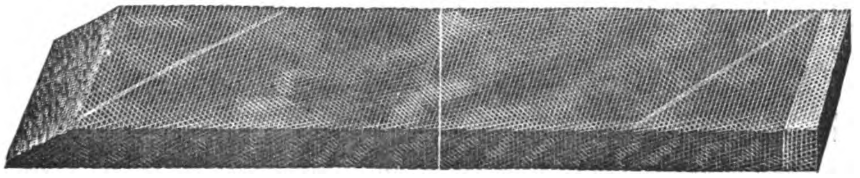
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE FLEMING DYNAMO BRUSH.

PROF. HOUSTON, in his "Dictionary of Electrical Words, Terms and Phrases," describes brushes for dynamo electric machines, as "strips of metals, bundles of wires or slit plates of metal or carbon, that bear on the commutator cylinder, and carry off the current generated." He also goes on to state that "brushes should bear against the commutator cylinder with sufficient force to prevent jumping and consequent burning, and yet not so hard as to cause excessive wear." The brush that we illustrate, for which letters patent have been granted to Mr. W. H. Fleming, E. E., of this city, has many features that commend themselves to all dynamo users. In the first place it is composed of wire gauze, the copper of which is from the Hecla mines, specially drawn and woven to a mesh of 3,600 to the square inch.

The brush is made up of one continuous strip of this gauze, no packing or other foreign substance being introduced, and by the process of manufacture is made to wear uniformly throughout its entire length, with no unravelling of the gauze and no sparking from loose ends. When sufficient gauze has been wound up to make a brush of the desired size, the somewhat loose roll is put into a mould of the proper size and subjected to a heavy pressure in a hydraulic press. In this operation the layers of gauze are pressed into a compact mass, the end of the strip being forced into the layer below so as to make a smooth joint. The brush therefore needs no sewing or other form of fastening, such as has heretofore been found necessary to bind the free end of the strip of the material. The brush, apart from its compactness, strength and durability, is exceedingly flexible. Adapting itself readily to the surface of the commutator, it is always in good metallic contact with it, therefore preventing to a large extent the sparking so destructive to this part of the dynamo.



THE FLEMING WIRE GAUZE DYNAMO BRUSH.

Manufacturers and central station men in all parts of the country, who have used this brush speak most highly of the results obtained. It has been placed on the market by the International Trading & Electric Co., of 40 Cortlandt St.

CARPENTER ENAMEL RHEOSTATS.

THE CARPENTER ENAMEL RHEOSTAT CO. as the assignee of C. E. Carpenter has recently had issued to it, a patent, which, it is claimed, controls broadly all commercial forms of enamel rheostats and heaters. The patent is No. 511,407 of December 26, 1893, and a sample claim reads as follows :

> Claim 1.—The improvement in the method of constructing resistances which consists in attaching to a suitable support a coating of enamel by fusing the same ; placing upon the surface of the coating an electrical conductor, covering said conductor with a coating of enamel having a fusing point lower than the enamel already applied, and raising the whole to a temperature sufficient to fuse said second layer of enamel, substantially as described.

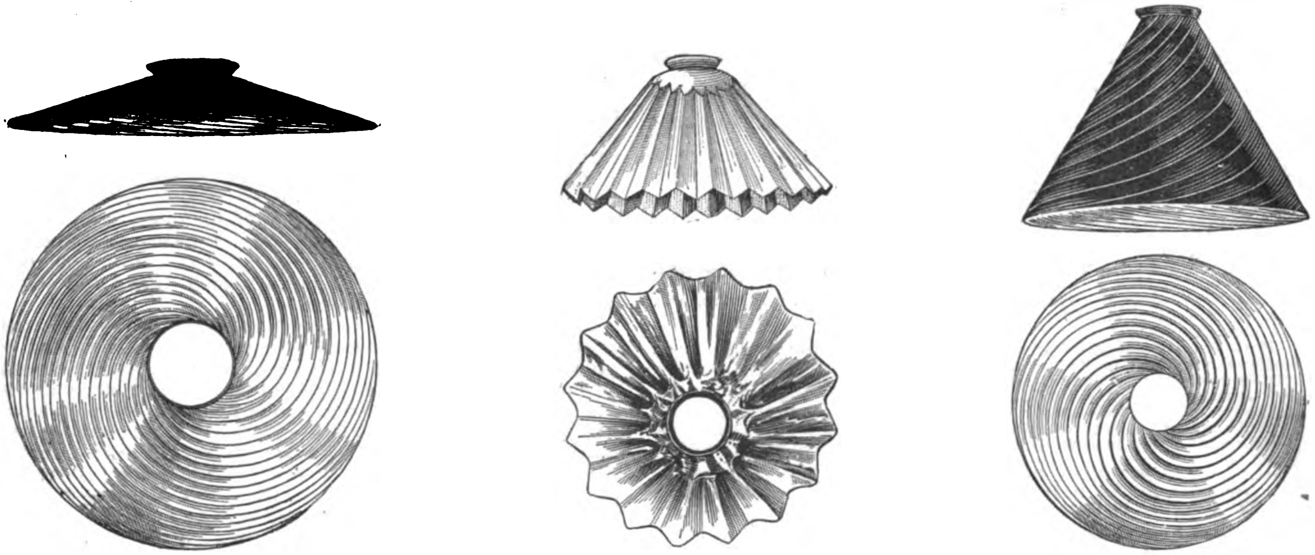
This company will immediately put upon the market a full line of electrically heated appliances, such as soldering irons, flat irons, and glue pots, various kinds of electrically heated tools and electric cooking utensils, such as chafing dishes, coffee pots, ovens, broilers, etc.

The rheostats of this company are now in almost universal use by manufacturers of electrical generators and motors, and by electric contractors. Their theatre dimmers and field rheostats, selling for about one-half the price of all former kinds and having such marked advantages as regards space and safety from fire, have really no competition, and the progressive policy of the company in continuing to make reductions in price, notwithstanding this, is in marked contrast with usual methods of charging high prices because of the protection of fundamental patents. The wisdom of this policy is evident from the favor, with which this rheostat has been received by the electrical public.

The following agencies of the company have recently been established: Walker & Kepler, Philadelphia; Sargent & Lundy, Chicago; Owen Ford, St. Louis; William Oswald, New Orleans.

GLEASON'S STANDARD SILVERED GLASS REFLECTORS.

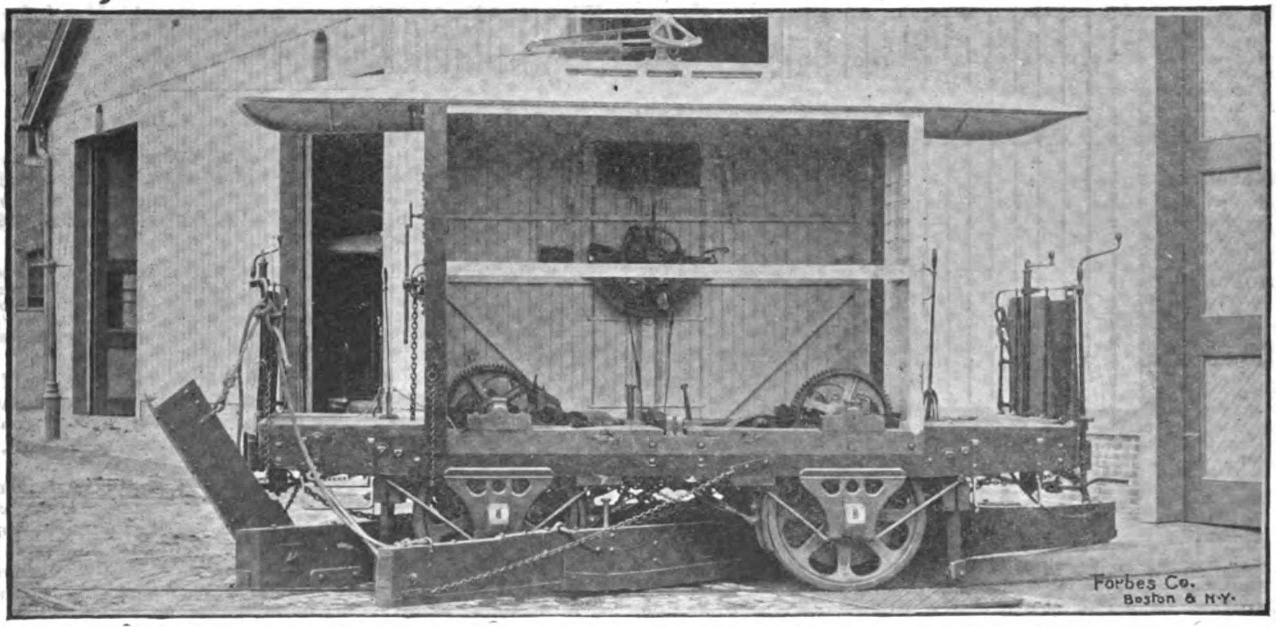
The E. P. Gleason Mfg. Co., of 181 to 189 Mercer street, New York, who are constantly adding to their already large assortment of appliances for electric lighting, are now introducing the new styles of silvered reflectors shown in the accompanying engravings. These are made in shapes of the staple electric shades, radial fluted and spiral corrugated, richly silvered inside, enameled green outside, and greatly increase the illuminating power of electric lamps. The reflectors, the company claim, are always bright, cannot tarnish, are easily cleaned and are very inexpensive. Besides this, they add to the ornamental appearance of the electroliers and fixtures to which they are applied.



Gleason's Standard Silvered Glass Reflectors.

THE TAUNTON ELECTRIC SNOW PLOW.

The Taunton Locomotive Manufacturing Co., of Taunton, Mass., are now building a snow plow for electric railways possessing a number of novel features under the Round patents. The accompanying illustration shows the plow just leaving the car house. It is operated by gear wheels instead of sprockets and chains, which often give trouble, and has a powerful brake which does not interfere with the shears.



The Taunton Electric Snow Plow.

As will be seen, the plow has a cab, with bonnets attached. The motors and all the electrical appliances are placed in the cab, with such tools as are needed. The cab is well lighted, so that the motors and all electrical apparatus can be seen at any time. There is also a light under each bonnet which lights up the track. Diggers are provided for clearing the ice and snow off the track, which can be pressed down with a lever, giving the wheel a good contact. The shears have shoes where they bear on the rails, thus preventing wear and also holding up the ends. These shoes are readily replaced when worn out, at slight expense. The motors are easily removed, and can then be used for summer work.

The plow is simple in construction, and all parts, such as shears and diggers, can be readily replaced. It is double ended, running either way without turning, plows a furrow nearly ten feet wide and requires but three men to run it,—one motor man, one man to attend to the diggers and shears, and one on the rear end to look after the trolley. Any style of street railway motor can be used.

THE "REPUBLIC" INCANDESCENT LAMP.

The American Electrical Manufacturing Company, of St. Louis, announces its new "Republic" incandescent lamps at prices to meet all competition. This is a new departure, and a practical business idea. Their well known "American" lamp has achieved such a reputation that the company is not willing to change its quality, or use any lower priced materials in its construction to meet the lower prices now prevailing. They feel a pride in maintaining the "American" which they claim to be the best that is made, and their steady flow of orders is the best evidence that their trade is willing to pay a fair price for a high grade article. In order to be in a position, however, to satisfy all conditions and meet all demands, they are now manufacturing the "Republic" lamp, to the details of which the same careful attention is given, but some materials are used, and some changes made in process of manufacture that reduce the cost. These lamps they guarantee for 600 hours average life, and state they are equal to any other in the market, except their own "American," for which they guarantee 1000 hours average life. The company notified its trade only a few days ago that the "Republic" lamps would be ready for delivery about February 1, and many large orders have already been received. A large increase in their factory capacity has been made to meet the demands for both grades of lamps.

CHICAGO ELECTRIC WIRE CO.'S CABLES.

We have received from the India Rubber Comb Co. of this city two sections of submarine cable made by the Chicago Electric Wire Co., for Government torpedo service. The former company, as agents for the latter, have sold about 84 miles of this cable in two sizes containing one and seven conductors, respectively.

The conductors in the single and seven conductor cables are alike. Each is made of seven strands of No. 22 B. W. G. copper wire having a conductivity of 100 per cent. The insulation, one-quarter of an inch in outside diameter, surrounds this conductor and is made of the best rubber compound obtainable, is guaranteed to have an insulation resistance of 2,000 megohms per mile. The actual resistance, however, under normal temperature is about 5,000 megohms per mile. The insulation is protected against injurious effects of the sea, either from moisture or other troubles common to submarine cables, by a thin covering of lead, less than one thirty-second of an inch thick, weighing one pound to each fifteen feet. This feature is an innovation in submarine cables and has proved a great success as it entirely excludes moisture. The cables from this point are built up, first by a layer of jute well saturated in tar; they are then armored over this layer of jute, the single conductor being armored with ten No. 13 B. W. G. galvanized iron wire, each covered with a layer of tape, and again tarred. The seven conductor cable is made in the same manner except that 16 No. 9 B. W. G. wires compose the armor. The cables are covered with two layers of best Russian hemp closely wound in opposite directions and are treated with a bath of tar which not only protects the galvanized iron wire from the action of salt water but also excludes all moisture from the cables.

In the manufacture of submarine cables for torpedo service there are a great many difficulties to contend with not experienced with ordinary cables used simply for telegraph. The greatest care in their manufacture must be taken as no chances can be taken on the failure of the cable when wanted for actual service in blowing up the war ship of an enemy. Cables, as generally made with rubber insulation, or in fact every other known substance are prone to deteriorate from inaction or storage. They may dry up and crack and eventually become useless and on this account the Government has been compelled to store the cables immersed in water in order to protect them from the drying effect of the atmosphere. This has been found to be unsatisfactory, besides being very expensive. The cable above described, however, entirely remedies this troublesome defect, the makers inform us. The thin coating of lead protects the rubber from the atmosphere and not only makes dry storage of cables possible but renders them absolutely impervious to injurious atmospheric effects. The advantage to the Government is not limited to the saving of expense incident to the storing of the cables, but the convenience of having the cables readily accessible in case of an emergency is said by naval officers to be of the greatest importance.

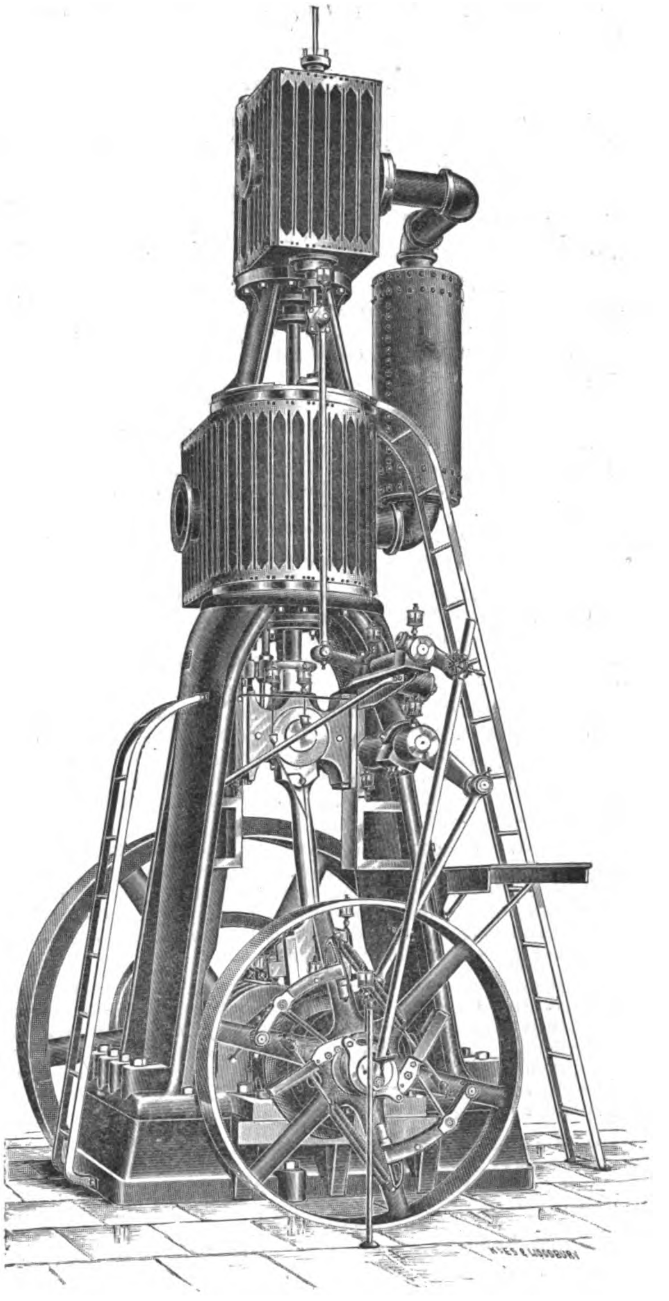
OHIO BRASS CO.

The Ohio Brass Co., of Mansfield, Ohio, has just commenced the sale direct of its electrical street railway specialties. This company has heretofore manufactured this line of goods for some of the largest street railway supply houses in the west; it will, from now on, however, sell its product direct from the factory in Mansfield. In making this change of arrangements, the opportunity is taken to bring out a number of novelties in street railway supplies, overhead material, line devices and car appliances which will interest all electric street railway people.

The officers of the company are, Mr. E. T. Cooke, president; Frank B. Black, secretary and manager. Both of these gentlemen have been interested in manufacturing enterprises for a number of years, and are prominent in business and social circles in Mansfield. The company has secured Mr. C. K. King as its electrical expert. Mr. King is well known in the profession, having for years been connected with the N. W. Thomson-Houston Co. and latterly with the Ansonia Electric Co., of Chicago. Mr. King has had a valuable experience in electric railway construction work both as an expert and as a salesman. A complete catalogue is now being prepared which will be ready for distribution on or about the fifteenth of this month.

THE FITCHBURG VERTICAL COMPOUND "STEEPLE" ENGINE.

The Fitchburg Steam Engine Co. of Fitchburg, Mass., do not intend to be behind in providing for the needs of the public in the steam engine line. The accompanying illustration shows one of two recently built by them for the Oakland Gas Light & Heat Co. of Oakland, Cal., and gives a good idea of its massive strength and graceful proportions. The height of the engine is about 20 feet from top to bottom. The high pressure cylinder is 16 inches in diameter, low pressure 27½ inches, stroke 20 inches, and the revolutions 210. The steam pressure under which it will run is 130 to 140 pounds with which it is expected to easily develop 400 h. p. The engines are connected directly to a heavy line shaft by means of Hill clutches, and the dynamos and motors are belted from this shaft, one engine being at either end of the line so that they can be run together or separately. All the parts of the engine are of the very best material and workmanship, the valves are expansible, as are all the valves used in the engines built by this company, providing for taking up all wear during the life of the engine without expense, while the original economy of the engine is retained. A cast iron lagging planed and polished, covers the cylinders and has nonconducting material beneath it to prevent all radiation.



The Fitchburg Vertical Compound Engine.

The crank shaft is 12 inches in diameter, made of the best forged steel; the bearings are 24 inches long, and the crank is carefully counter balanced for centrifugal force and the weight of the reciprocating parts. The guides are bored and the gibs are adjustable for all wear. The high pressure cylinder has direct connection with the automatic cut off, giving complete control of the engine and a possibility of cutting off as late as ¾ stroke. The low pressure valve motion is driven from an adjustable eccentric attached to the back of the governor case. The engines are absolute in regulation of speed, are of the closest economy in use of fuel and give a very large power in a very small space. A steam jacketed receiver between the two cylinders reheats the exhaust from the high pressure, giving it a slight superheat as it enters the low pressure, the receiver being also jacketed with an outside covering to prevent radiation. Deane independent condensers are used with the engines. These engines permit either direct connection to the line shaft or to the armature of a dynamo, or can be belted to the dynamos or shafting.

NEW YORK NOTES.

Buffalo, N. Y.—There is some discussion of a small preliminary municipal lighting plant for Buffalo, but the existing contracts run until 1897.

The Palermo Mica Co., S. T. Peckham, sales manager, 27 Peck Slip, have issued a neat circular of their mica for electrical purposes, in the various sizes and kinds of New Hampshire mica and "Silver Amber" sheet mica.

The Electrical Construction & Supply Company, of Buffalo, are introducing the American cycle compound for lubricating the chains of bicycles. It is claimed to reduce friction greatly, prevent wear and rusting and make the chain bearings waterproof.

The Springville Waterworks Co. of Springville, N. Y., have secured a franchise for electric lighting, and have already purchased an alternator of the Fort Wayne Electric Co. of Fort Wayne, Ind. The Fort Wayne Company have also secured from the city of Batavia a contract for 120 arc lights of the celebrated "Wood" system.

NEW ENGLAND NOTES.

The Hart & Hegeman Manufacturing Company, of Hartford, Conn., are working ten hours a day with a full complement of men, and are still behind hand on orders. They have not yet had a dull day this winter, a most extraordinary state of affairs considering the times.

The Eddy Electric Manufacturing Co. of Windsor, Conn., have recently received some very warm testimonials relating to their new power generators, and are well pleased at their success in this line. Meantime they are working with a reduced force, but orders are picking up every day, and they expect soon to be in full blast again.

The Brown Electric Company of Boston, have secured the exclusive agency for New England, for the well known specialties in sockets, switches, etc., manufactured by the Iona Manufacturing Company of Boston. The Brown Company are doing a large business also in electric railroad specialties, and have a number of contracts at present under consideration.

I. S. Spencer's Sons, at Guilford, Conn. have an extremely well appointed foundry for turning out iron and brass castings for electrical use, and have been fairly busy during all the months of depression. They make a specially fine casting for small articles, the outsides being as smooth as glass. All electrical manufacturing companies requiring castings would do well to correspond with them.

The Grosvenor-Dale Co., Grosvenor-Dale, Conn., are building their new coal sheds of iron. The construction is designed and built by The Berlin Iron Bridge Co., of East Berlin, Conn., and is so arranged that the coal can be unloaded direct from the cars into the pockets without handling. It is expected to save a large amount of money each year by abolishing the expense of handling their coal the second time.

Mr. Robert C. Wiggin, of Boston, has resigned his position as manager of the motor department of the General Electric Company, and has taken the agency of the Siemens-Halske Company of Chicago for New England. In addition to this, Mr. Wiggin will carry all the specialties of Mr. Charles D. Shain of New York, such as Weston instruments, Carpenter rheostats, etc., and will act in a general way as Mr. Shain's representative in New England. Mr. Wiggin has taken offices at 31 Milk street, Boston, where he will be very glad to see his numerous friends, and introduce them to his new apparatus.

Currier, Mayo & Company, of Boston, have succeeded to the business of J. A. Grant and Company, the well known agents of the McIntosh, Seymour and Company of Auburn, N. Y. Mr. Currier, who has for some years been associated with Mr. Grant, in the firm of J. A. Grant and Company, and is very favorably known in New England, will assume the active management, and Mr. Grant, though still interested in the company, will be relieved so as to attend to his many other business affairs. The capital of the old company remains the same, and they will retain the same offices at 16 Oliver street, and handle precisely the same specialties.

The Perkins Electric Switch Company of Hartford, Conn. promise soon to have a new line of switches, which they feel confident will meet with instant approval. Meantime they are busy with their regular specialties in sockets, switches, etc.

The Day-Moberg Electric Company of Boston, have recently put on the market a new form of storage battery which they call the "Jupiter." It is not at present intended for heavy work, such as street railway, or house lighting, but is well adapted for phonograph, dentists' and physicians' use, cautery, electro-plating, bank vaults, watchmens' and conductors' lanterns, photographers' dark rooms, small motors, and a host of other uses. It is portable in form, will stand a great deal of rough handling, and is constructed specially for the use of people who do not understand the care of batteries. It is intended for use at all times, is always ready, will not get out of order, and will stand an immense amount of wear and tear. For its own field, it is the best thing in the market, and is the design of Mr. Moberg, who has spent years in developing a battery of real practical use. Mr. Day, the business man of the company, will be glad to show the battery to any one interested and will mail full particulars on application.

WESTERN NOTES.

Grand Rapids, Mich. The street railway company at Grand Rapids has decided to build its own electrical apparatus, and is buying machinery, etc., for the purpose.

The Electric Storage Equipment Co. has been incorporated in Chicago with a capital stock of $250,000, to manufacture electric storage batteries under the Fenton and Elliot patents which the incorporators, R. W. Applegate, O. R. Stratton and H. B. Lindley, have purchased from the original holders.

The General Electric Company has secured commodious offices on the tenth floor of the Monadnock Block, Chicago, where all Chicago business will be transacted. The old offices on Adams street will be given up and all the officials will hereafter be quartered in the Monadnock. The new rooms are now undergoing subdivision to adapt them to the needs of their new tenants.

The Electric Appliance Company have been keeping a large extra force busy for the past few weeks taking care of the large shipments which are being received and placed in stock in preparation for spring business. The Appliance Company are materially increasing their storage and shipping facilities and when the alterations are complete their arrangements for promptly handling large orders will be perfect.

The Walker Mfg. Co., of Cleveland, O., has taken spacious quarters on the sixteenth floor of the Monadnock Block, Chicago, at the Van Buren street end. This office will be in charge of Mr. H. L. Barclay, who will look after the western interests of the Walker Company's new business in the manufacture and sale of electric railway motors. Mr. Barclay's office will be open for an active campaign in a week or ten days.

The Star Electric Lamp Company, Chicago, manufacturers of the Sunbeam lamp have changed their name to the Sunbeam Lamp Manufacturing Company. The policy of this company is to furnish lamps superior in quality. Recently some discoveries have been made, as the result of the extensive experiments they have carried on, which they claim will greatly improve the quality and add to the value of their lamp.

The Chicago Electric Truck Co. has opened an office at 1,436 Monadnock Block where Mr. Geo. H. Graham the inventor of the truck to be exploited and the vice-president of the company is in charge. The company has just been incorporated under the laws of Illinois with a capital stock of $25,000. Mr. Graham's truck is designed especially for electric street car service and possesses, it is claimed, many advantages for that class of service.

CANADIAN NOTES.

The Packard Lamp Co., Ltd., of Montreal.—The "Packard" high grade incandescent lamp manufactured by this company is meeting with great success and is making a name for itself abroad as well as in Canada as appears by several orders recently received for export, among which was one for 10,000 lamps for Brazil.

Electrical Engineer.

Vol. XVII. FEBRUARY 14, 1894. No. 302.

EFFECT OF FREQUENCY IN INDUCTION MOTORS.

BY

William Stanley, Jr.

We have lately been informed that, all things considered, a low frequency—as low as 25 per second—"is the proper thing" for the "transmission of power by alternate currents." In this paper the writer discusses some of the points why, from the alternate current motor side of the question, the use of very low frequencies is not justified, and in a subsequent paper he intends to show why such a procedure is bad engineering from the transformer standpoint.

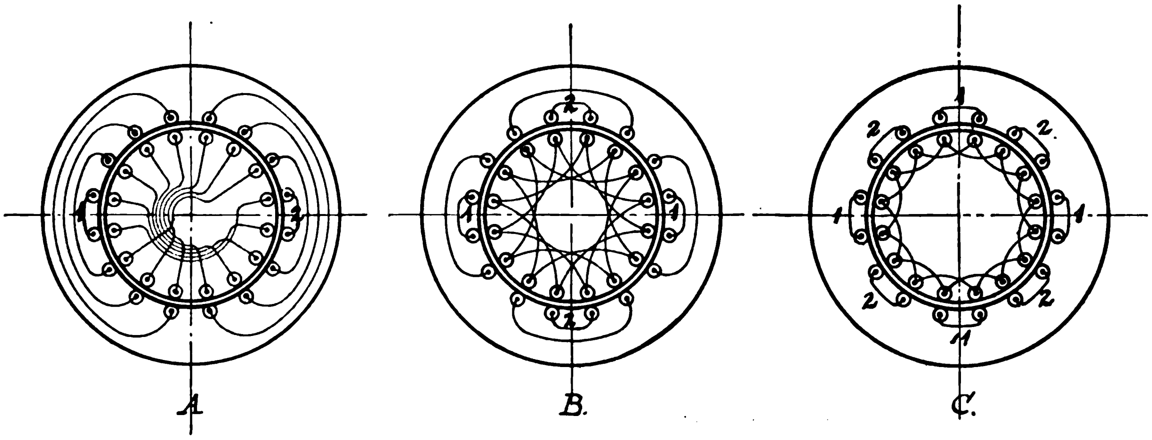

FIG. 1.

In the accompanying diagrams, Fig. 1, A, B and C are illustrated three induction motors connected for frequencies $n = 1$, $n = 2$, $n = 4$; say, 33, 66 and 132 periods per second. The cores of these motors are supposed to be exactly alike, to have the same number of slots and wires in the primary or field rings and similar armatures. The primary wires of A are grouped to produce two poles at 1 and 2, the secondary or armature circuit being connected as diameters. The primary wires of B are grouped in four sets producing four poles (two magnetic circuits) and the secondary or armature conductors are connected at points 90 degrees apart, as shown. The primaries of C are grouped to produce eight (8) poles and the secondaries are similarly arranged.

I propose to show that although the number of wires, speeds and fluxes in the three motors are the same, yet the starting torques and outputs of the motors are not the same, as would appear at first sight, but are greater in B than in A, and greater in C than in B, and that the use of induction motors on alternate circuits gives us no excuse for decreasing the frequency of a motor plant below the frequency best adapted to other interests.

To begin with, let us look at the constant and variable quantities delivering the torque and work developed by a motor, and then consider the relation of these quantities in the torque and work equations in the cases assumed. The quantities having assumed constant value in the three cases are :—

CONSTANT QUANTITIES.		VARIABLE QUANTITIES.
Impressed E. M. F.	same value for three cases.	R of field and armature circuits. C < B and B < A, the value of L (coef. of induction) varies $L_A = 4L_B$ and $L_B = 4L_C$; that is to say, in the three cases the coef. L for primary and secondary circuits varies inversely as the square of the frequency.
Rotational speeds (synchronous)	" " "	
Fluxes entering armature	" " "	
Number of field wires	" " "	
" " armature wires	" " "	

From these data we see that notwithstanding the fact that we have doubled the frequency of Case A in Case B, and doubled the frequency applied in Case C above Case B, yet by increasing the *number of magnetic circuits* proportionately to the increase of applied frequency in order to keep the speed of the motor the same for the three cases, we have actually reduced the self-induction factor opposing the flow of current in the motor circuit. In order to clearly appreciate the importance of these variable values of L and R and their relation to the output of an alternate current motor, let us express the work done by a motor armature in terms of the primary current, frequency, armature resistance and armature self-induction.

Let A = Maximum value of the primary current.
ρ = Resistance of the armature conductors.
M = Coeff. of mutual induction.
L = Coeff. of self-induction of the armature.
n = Impressed frequency.
n_1 = Armature frequency.
$\omega = 2\,\pi n$.
$\omega_1 = 2\,\pi n_1$ and $\omega - \omega_1$ = armature slip = ω_2.
ω_2 = slip.

$$\text{Work} = \frac{\omega_1\,\omega_2\,\rho\,M^2\,A^2}{\rho^2 + \omega_2^{\,2}\,L^2}.$$

A little examination of this formula will show that for any given ratio between ω_1 and ω_2, the work will be greater, the higher the value of ω. This is assuming M to be constant. It is actually, however, a variable depending on the armature reaction. This latter, of course, is measured by the number of armature ampere-turns multiplied by the sine of the angle of lag,

$$\frac{\omega_2 L}{\sqrt{\rho^2 + \omega_2^2 L^2}}.$$

That is to say, the doubling of the frequency applied to the motor in the case assumed reduces the self-induction E. M. F. in the armature to $\frac{l}{2}$ its original value, and from structural causes decreases somewhat the resistance of the armature. The lag of the armature current at a higher frequency will therefore be *less* than at a lower frequency, and the volume of the current for a given amount of work will consequently be less, as the work done by the armature varies as cos θ.

Now an alternate motor of any number of phases or frequency is nothing more or less than a poor transformer, having a movable secondary circuit. It is a poor transformer because of the consequent pole effect occurring between the primary and secondary circuit. It is impossible to so locate the primary and secondary circuit that the mutual induction shall remain constant. If the armature current lags at all,—as it must, to have the motor work,—the armature current opposes and tends to demagnetize the primary circuit, as there is necessarily an opening between the primary and secondary coils at the air gap of the motor, and as the primary circuit is on one side of the air gap, and the secondary circuit is on the other side, the demagnetizing action af the armature tends to scatter the primary flux driving it sidewise out of the air gap, as shown in Fig. 2.

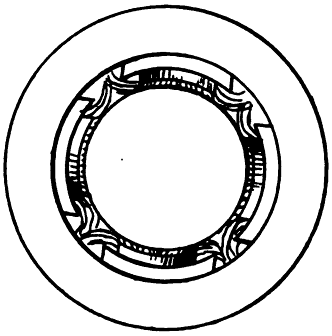

Fig. 2.

This armature reaction is termed "blowing out," and is simply the result of the lagging armature current. The "blowing out" depends on the ampere-turns of the armature and on the lag of the armature current, being maximum when the ampere-turns on the armature equal the ampere-turns on the primary and the armature current lags 90 degrees.

Now in the energizing circuits of A and B, Fig. 1, the ampere-turns per magnetic circuit are the same; but in the armatures A and B the difference is great. The number of turns per magnetic circuit in the armature is but one-half as great in B as in A; the currents in the two armatures are inversely as the cosines of the lag angles, and the demagnetizing effects directly as the sines of those angles. The effective demagnetizing turns vary as $t \frac{\sin\theta}{\cos\theta}$, θ being the angle of lag and t the number of turns per circuit. This is equivalent to saying that the demagnetizing effect varies as $\frac{\omega_2 Lt}{\rho}$, L being but one-quarter ($\frac{1}{4}$) and t one-half ($\frac{1}{2}$) in B what they are in A, while ω_2 is less than twice as great. It is clear that the force acting to lower the mutual induction is practically four times as great in A as in B.

To sum up, then, the virtues of high frequency motors, we have:

First:—A greater torque at all times for the material employed, and, consequently, a greater output.

Second:—A lower impedance armature and a lower inductance in the armature circuit, consequently for a given load a smaller armature current.

Third:—A smaller armature reaction and "blowing out" effect produced by armature reaction.

For what possible reason then have the engineers of the Cataract Construction Company ventured to adopt a frequency of 25 for their motor circuit? Is it because of the volume of the lagging currents at higher frequency? Surely the experience at Pittsfield, where for fifteen months two-phased motors whose magnetizing currents are supplied from condensers have been in operation, is a sufficient proof of the practical operation of condensers. These motors are operating at 130 periods per second. They are connected to all classes of work, operating, as they do, a saw mill, a woolen factory, machine shops, a printing office, etc., and it has been found by actual observations of the voltmeter, in circuit on the consumers' premises, that the variation of potential due to changes of load and lag on the motors does not average 2 per cent. of the voltage applied. The regulation of these circuits is as perfect as if they were simply operating lamps alone.

Prof. Forbes in his paper before the English Institution of Electrical Engineers justified the low frequency adopted at Niagara on the ground of a decrease in hysteretic loss. If he had figured the hysteretic loss per h. p. of output from the motors, and especially if he had taken into account the hysteretic loss in his transformers, he would have found that he would have to pay for the 42 per cent. he intends to save, but even were these figures correct (and we believe they are not), it is 42 per cent. of from 5 per cent. to 10 per cent. in a good motor,—not 42 per cent. of the energy applied to the system, but 42 per cent. of the hysteretic loss. Can the engineers of the Cataract Construction Company give any other reason for thus taking the life out of the alternating currents they intend to employ?

PROF. ROWLAND'S METHOD OF COOLING TRANSFORMERS AND CONDUCTORS.

In order to carry off the heat generated in transformers working under a heavy load Prof. Henry A. Rowland, of Johns Hopkins University, has invented a method employing a current of liquid led through the iron in tubes so placed as not to be cut by the lines of magnetic induction, the tubes and iron laminæ alternating with one another. Water or any other conducting liquid may thus be employed without interfering with the proper working of the transformer.

Another method employed by Prof. Rowland is to surround the transformer with a vessel containing a volatile liquid which, by boiling, carries away the heat. The vapor may be recondensed in the upper part of the vessel or carried off through a condensing coil and returned to the vessel in a liquid state. He also provides means for reducing the pressure in the vessel, in order that the liquid may boil at a low temperature.

To cool conductors carrying heavy currents, Prof. Rowland suggests making them hollow and passing a current of cooling liquid, such as water, through them from end to end, the liquid issuing in the form of spray to break the continuity of the stream and thus insulate it from the vessel into which it flows.

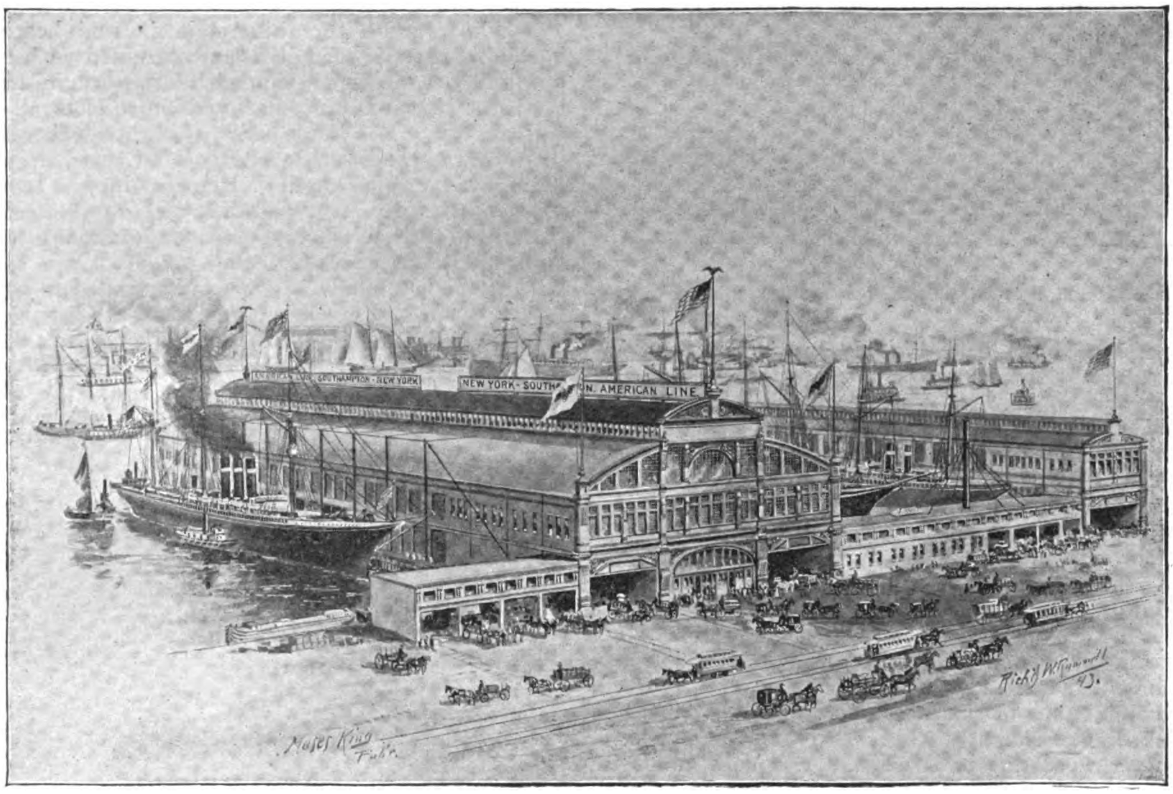
Professor Von Helmholtz has been elected an honorary member of the London Institution of Civil Engineers. The total membership is 6,490, but there are only fifteen honorary members.

THE FINEST PIER IN AMERICA.

ELECTRICAL FEATURES OF THE INTERNATIONAL NAVIGATION COMPANY'S NEW YORK HOME.

I.—THE PIER.

THE International Navigation Company, owning the American and Red Star lines of transatlantic steamers, have nearly completed what is said to be the most perfectly equipped, as well as the largest, pier in the country. Beginning at the North River front on West street, between Dey and Vesey, the pier extends 720 feet into the river and has a uniform width of 125 feet. It is thus only a few minutes' walk from the Barclay street, Park place and Cortlandt street stations of the Ninth and Sixth avenue elevated railroads, and within five minutes' walk of the Broadway cable cars.



THE INTERNATIONAL NAVIGATION CO.'S NEW "AMERICAN LINE" PIER, NEW YORK.

It is also in the immediate vicinity of the New York terminal of the Pennsylvania road, at Cortlandt street ferry; the Central Railroad of New Jersey, the Baltimore and Ohio, the Reading, the Delaware, Lackawanna and Western; the West Shore, the Ontario and Western, the New York, Lake Erie and Western and the Fall River line of boats.

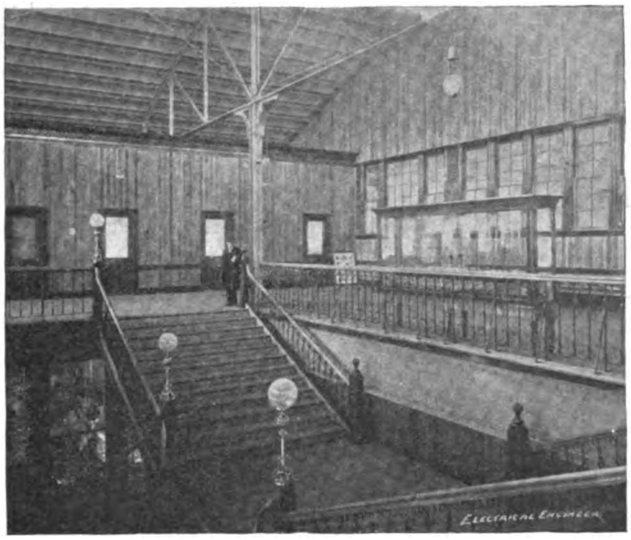
The pier has been leased from the city for ten years at an annual rental of $50,000 and the company has built upon it an enormous two storied "shed," so called—a masterpiece of light but solid iron work—for the convenience of passengers and the handling of freight. The building is the full width of the pier and extends to within 125 feet of the river end. The second floor will be wholly given up to cabin passengers, who will reach it directly from the main decks of the steamers and avoid the nuisance and discomfort of being indiscriminately mixed up with baggage, freight, cabs, trucks, etc. At the eastern end is the grand stairway leading by low, wide steps from the floor below, and a passenger elevator. Here, also, are the waiting rooms and offices, finished in hard natural wood and fitted with all the modern conveniences that one sees in well appointed railway depots. The lower floor, level with the street, is given over to freight, and the offices of the shipping department.

The Commercial Cable Company and the Western Union Telegraph Company have booths on the upper floor, and a public telephone service will also be furnished. The consideration of expense has not been allowed to stand in the way of the very best work in every case, and the whole cost of the building and fixtures has been something over $300,000.

II.—THE POWER PLANT.

In addition to a Sturtevant hot blast apparatus for heating and ventilating the offices, etc., the power plant contains the usual fire pumps, etc. The two boilers are ten feet six inches in diameter and eight feet seven inches long, built entirely of steel. They are of the cylindrical, single ended, return tubular or Scotch type of marine boiler, built by Brown & Miller, of Jersey City. Each has two furnaces with flanged expansion rings and separate combustion chambers. They are so fitted up that they may be run either under natural draft or under a system of induced draught, although under ordinary conditions the natural draught is sufficient to generate all the steam required; still at times, such as on the arrival of ships when an extraordinarily large supply of steam is needed for power and light, the boilers are enabled to give three times their usual power. This system is that of the Ellis & Eaves patent, which has of late been successfully introduced in steamship practice and gives promise of becoming very popular, as it is said to possess many advantages over other systems of forced draught.

The fan used is of a special type built by the B. F. Sturtevant Co. with a direct driven wheel eight feet in diameter discharging into the stack and calculated to give a suction of six inches of water. This fan draws off the waste gases, which, in their transit from the smoke box over to the fan at the back of the boilers, pass longitudinally around sets of three-inch plain tubes thirteen feet long in heater boxes. The ash pit and fire box doors are tightly closed on the furnace fronts, and the fresh air for the fire is drawn through the tubes in the heater boxes, where it is heated to a high temperature, and the amount passing above or below the fire is regulated by butterfly valves in the furnace front. In this manner the waste gases are deprived of considerable heat, and arrive at the fan at a low temperature. When a firedoor is opened, it automatically closes a large butterfly valve in its uptake, thus preventing cold air from being drawn into the fire and preventing the chilling of the furnace and combustion chamber. As there is no suction of air during that time through that particular furnace its supply of hot air ceases. This item alone is of considerable value, as in some forced draught systems the fireman must close all his blast valves before opening a door to prevent the fire being blown into the fire room.



Grand Staircase, International Navigation Co.'s Pier.

Experience has proved that, for any style of forced draught, boiler tubes of small diameter are too apt to become choked, consequently tubes three and one-quarter inch diameter were put in these boilers; plain tubes in one and Serve's patent ribbed tubes in the other. To prevent the too rapid passage of gases through them, retarders, consisting of strips of thin steel, the width of the inside tube diameter, and of the same length as the tube and twisted into a helix of about two turns are introduced into them causing the gases to revolve, and give up more of their heat, and still further increasing the efficiency of the boilers. Retarders for Serve's tubes are the same as for plain tubes, except that they are made narrower to fit between two opposite ribs, and in some cases plugged pipes are also used.

The Serve's patent ribbed tubes are now coming into extensive use, especially in steamship practice, and the company will now be able to make good comparisons with the plain tubes under different conditions. The plant is not quite completed so that there have been no tests as yet, but the patentees of the system have been able to burn as high as 60 pounds of coal per square foot of grate in their boilers at Sheffield, England, thus practically making two boilers do the work of six. As the boilers have ample steam and water capacity and all necessary precautions are taken against priming, etc., the care involved in running them is no greater than under ordinary conditions, the only difference being that the stop valve of the fan is manipulated instead of the ashpit doors.

The designs and plans of the power plant were made under the supervision of Mr. Jas. S. Doran, Superintendent Engineer of the International Navigation Co. and his assistant Mr. George Clarke.

III.—THE STURTEVANT HIGH SPEED ENGINE.

The Sturtevant engine is of entirely new design in every particular; a radical departure from engines previously built by the B. F. Sturtevant Co., and distinctively a high speed engine. Years of experience in the operation of fan blowers which require continuous running at high speed has given this company a thorough appreciation of the requirements of this work, which is so similar in its nature to electric lighting. This particular type of engine was designed primarily for dynamo driving either by belt or direct connection. The features of compactness, accessibility, economy and stability, with consistent lightness of parts, together with the ability to maintain an excessively high speed during a long continued period, are the result of careful study and design.

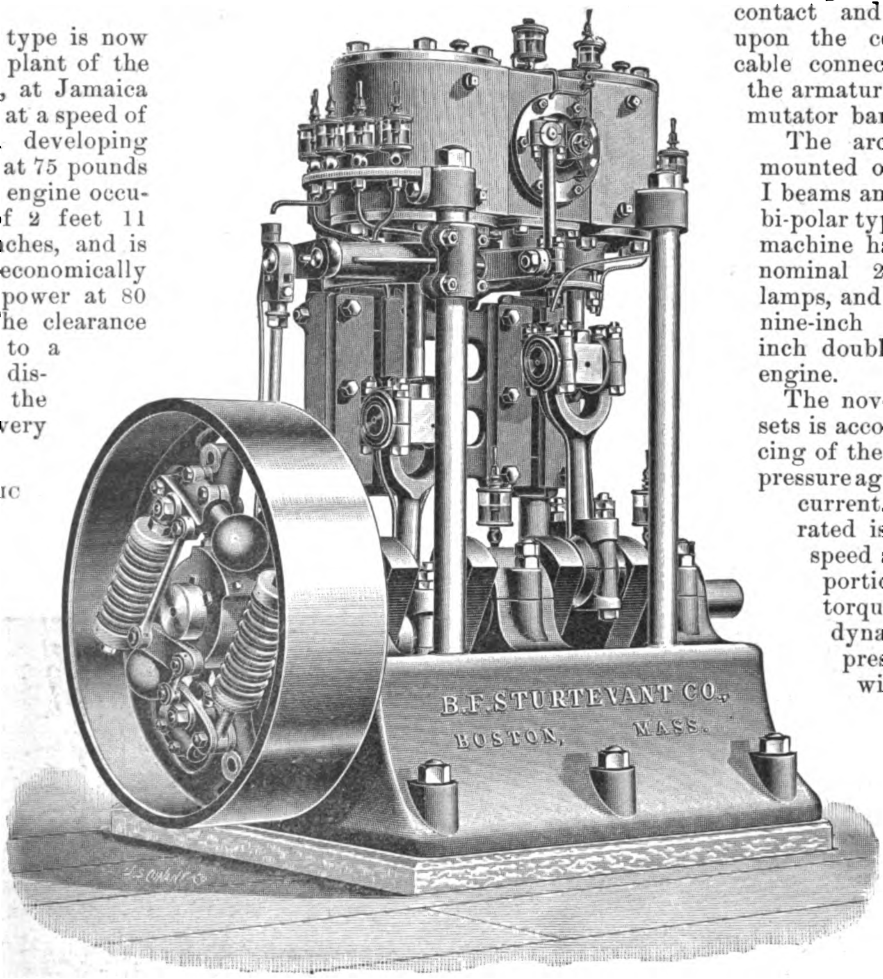
The bed carries the three main journal bearings, brass bushed in their lower halves and provided with continuous oiling devices in connection with oil reservoirs beneath; its interior is formed into a basin which collects all drip from water or oil. The four heavy upright steel columns are securely fastened to this bed and to their upper ends is bolted the cylinder casting. The engine has two cylinders of proportionally large diameter and short stroke, the engine from which this cut was made having cylinders 9 inches in diameter by 5½ inches stroke. The special feature of this engine is a single valve operated to admit steam to the upper end of one cylinder and the lower end of the other at the same time, also attending to the exhaust from the other ends of the two cylinders. This valve is cylindrical in shape with ports parallel to its axis; its ends are extended and form taper bearings, or trunnions, which are carried in special brass taper bushings, abjustable to take up all wear. By this means the valve is always maintained central within its bushing and friction on the valve seat avoided. The entire wear comes upon the trunnions and it is therefore possible to maintain a steam tight valve. The valve simply oscillates, being operated by rocker and rods directly from the eccentric upon the regulator. This

Façade of The International Navigation Co.'s Pier.

regulator is extremely strong, yet sensitive; it controls the admission of steam between zero and ¾ cut off and is capable of the finest adjustment for regulation. A brass dial is provided upon the end of the valve stem whereby the action of the valve is readily shown.

The cross heads are of the slipper type, the cross head pins forming extensions of that part of the cross head into which the piston rod is screwed, and the connecting rods have yoked wrist pin ends and are of large size. The connecting rods and cross heads are of forged steel and all parts of the engine are of the highest grade as regards material and workmanship. Special attention has been paid to the lubrication, separate oil cups being provided for each of the moving parts and all of the oil cups except those upon the main journals being placed upon bars at either end of the engine with tubes dropping oil into catch cups upon the various running parts.

An engine of this type is now driving the electric plant of the B. F. Sturtevant Co., at Jamaica Plain, Mass., running at a speed of 540 revolutions and developing about 65 horse power at 75 pounds steam pressure. This engine occupies a floor space of 2 feet 11 inches by 5 feet 2 inches, and is readily capable of economically developing 75 horse power at 80 pounds of steam. The clearance spaces are reduced to a minimum and the discharge of steam to the cylinders is made very direct.



The New Sturtevant Vertical Engine.

IV.—THE ELECTRIC PLANT.

The electric plant was constructed and installed by The Electro-Dynamic Company of Philadelphia, and consists of two incandescent light, compound wound, direct coupled dynamos, of 400 16 c. p. lamps each, running at a constant speed of 450 revolutions, and two 50 arc light, direct coupled dynamos, the speed of which is governed by the load, running 500 revolutions per minute for full load and proportionately less for lighter loads. All circuits are controlled by switches in the dynamo room. The incandescent switchboard is of slate equipped with one main knife switch and one main ammeter for each dynamo; one combined voltmeter and ground detector, which gives the ground reading directly in ohms; and six double-pole, double-throw knife switches for the different circuits. The switches are all mounted on slate and are so arranged that any circuit can be run on either dynamo. The ammeters and voltmeters deflect on either side of the zero of the scale, and the steel magnets used in their manufacture go through a special process of magnetizing and ageing which gives them a great constancy.

The arc light switchboard is also of slate, and has mounted upon it one ammeter and two lightning arresters for each dynamo, and five sets of plug and socket switches for as many circuits. There are also transfer plugs and socket switches all arranged so that any circuit can be run from either dynamo, and any circuit can be cut in or out without disturbing the sets while running.

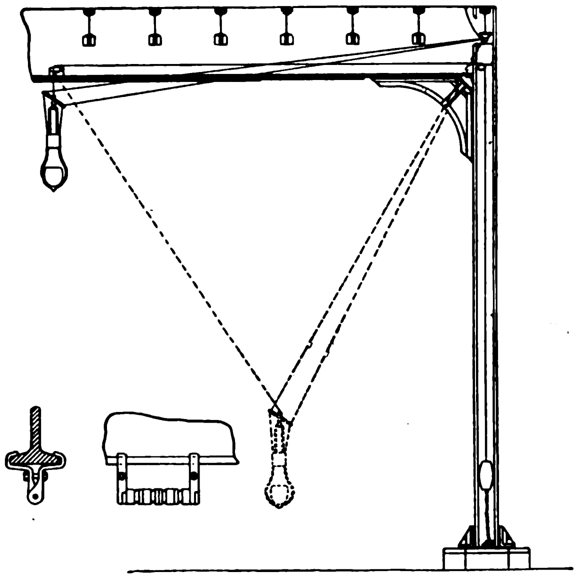
The incandescent machines are of the bi-polar Gramme ring type, compound wound, each with its engine mounted on a common bed plate of I beams and cast cross pieces carefully fitted and snugly riveted together, and directly connected to double upright automatic Sturtevant engines, having cylinders seven inches in diameter by five inch stroke, and running at a speed of 450 revolutions per minute. The dynamos have large ball bearings, bronzed bushed and self-oiling, with a wick feed which delivers to them filtered oil free of grit. The commutator is of tempered copper, mica insulated throughout, with ample wearing surface. Carbon tipped copper brushes are used which give great flexibility of contact and produce little wear upon the commutator. Flexible cable connections are used from the armature winding to the commutator bars.

The arc light dynamos are mounted on bed plates made of I beams and are of the Gramme bi-polar type, series wound. Each machine has a capacity of fifty nominal 2,000 c. p. double lamps, and is coupled direct to a nine-inch by five-and-one-half-inch double upright Sturtevant engine.

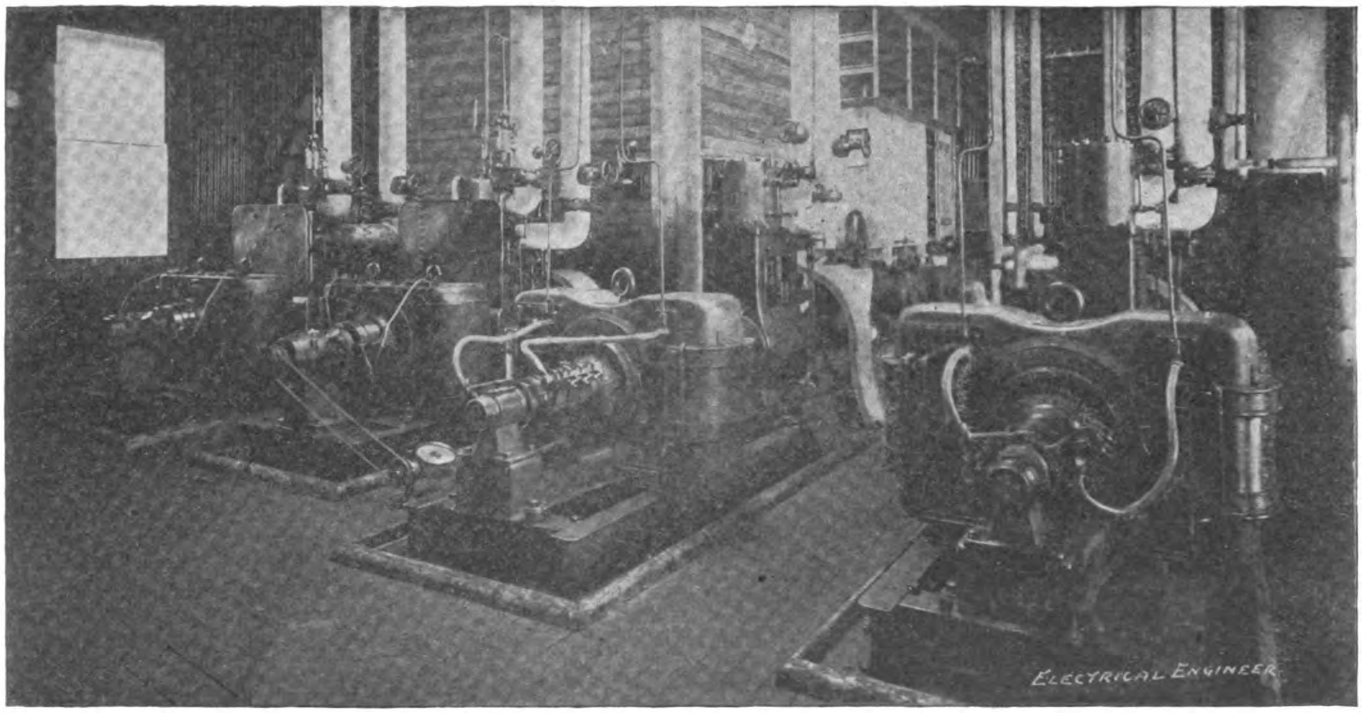
The novel regulation of these sets is accomplished by a balancing of the torque of the steam pressure against the torque of the current. The E. M. F. generated is proportional to the speed and the current is proportional to the pounds torque of the shaft of the dynamo. A constant steam pressure on the piston with fixed cut-off gives a constant torque on the shaft and constant number of amperes in current. The power used is the product of the pounds of mean effective pressure by the speed, and also the product of the amperes and volts; hence, if the steam pressure is kept constant, the torque in pounds on the shaft and the amperes flowing will be constant and the voltage will vary with the speed. Or, in other words, when more lamps are put in circuit the engines will run faster, and when lamps are cut out, the engine will run slower, which would ordinarily seem paradoxical. With this system, a short circuit will slow the speed of the engine instantly, without damage to any of the parts.

V.—THE WIRING.

In the wiring for the lamps installed on the pier great care has been exercised in the method of thoroughly insulating the wires from the building, and especially in the method of the suspension of the arc lamps. From the polished slate incandescent switchboard in the dynamo room two mains for the incandescent lighting are run to a central distributing board placed in one of the waiting rooms leading from the grand stairway. The sub-feeders are run to three other slate distributing boards placed in various parts of the building, which in turn feed the respective circuits. The lighting is divided up into two circuits, one known as the general lighting circuit, and the other as the police, or all night circuit, both controlled from the main switchboard in the dynamo room. There are also run directly from the switchboard two independent circuits, one on each side of the pier, controlling the twelve cargo outlets for flexible cable to furnish light for the cargo lanterns used in the work of loading and unloading ships at night. Grimshaw white core wire has been used throughout for the incandescent work, while a high grade of fire and weather-proof wire manufactured by the Roeblings has been used for the arc lamp circuit, except that where the wires are connected in loops to the arc lamps on the outside of the building, Grimshaw flexible cable is employed.



METHOD OF HANGING THE ARC LAMPS.



ELECTRO-DYNAMIC CO. LIGHTING PLANT ON THE NEW PIER OF THE INTERNATIONAL NAVIGATION CO., NEW YORK.

The method of lowering the arc lamps on the first floor of the pier is novel. The device consists of two pulleys one fastened on the centre of the web of a cross girder and the other between the flanges on one of the vertical columns supporting the second floor. A steel rope is run from the cross-arm connected to the lamp, and over these pulleys to a balancing weight of such dimensions as to slide easily up and down the column. On the lower end of this weight is a chain so that the lamp can be pulled down and hoisted back into its place. When the lamp is lowered the loop wires draw it towards the foot of the column making a V-shaped angle with the rope suspending the lamp. All lamps are also hung with intermediate insulators so as to thoroughly protect their frames from the iron in the building.

The arc lights on the outside of the building are hung upon iron cranes arranged to swing back against the windows, so that the lamps can be trimmed without being lowered. Those at the two corners of the river front can also be swung around to light the slip if necessary.

The wiring of the pier was carried out by the International Trading and Electric Company, of this city, in accordance with the plans and specifications of the Electro-Dynamo Company, of Philadelphia, and under the supervision of their engineer. It is gratifying to know that the only transatlantic line flying the Stars and Stripes is also the possessor of the finest pier in America, provided with the most modern system of electric lighting.

THE TELEPHONE PATENT SITUATION.—V.

THERE seems to be a prevailing superstition that a non-infringing form of magneto generator, when once secured, may be used in connection with telephone circuits without infringement; it may be so used provided it be permanently connected in series with the telephone instruments. The moment an organization of circuits is employed, however, in which the magneto calling apparatus is in circuit while ringing up, and is out of circuit while conversation is being carried on, a patent of Thomas A. Watson is infringed. This patent is dated April 16, 1878, and is numbered 202,495. The claims are as follows:

> 1. The combination, with a system of electric telephones, and upon the telephonic circuit, of signaling apparatus and a supplemental electric generator in a branch circuit independent of that containing the telephone, the whole being arranged and adapted to call the attention of distant operators, substantially as shown and described.
>
> 2. The combination, with a system of electric telephones, of a supplemental magneto-electric inductor in an independent branch circuit, substantially as shown and described.
>
> 3. The combination, with a system of electric telephones, of magneto-electric inductors and call-bells with polarized armatures, the whole being operated substantially as shown and described.

It will be readily seen that any form of magneto generator which is alternately in circuit and out of circuit, infringes this remarkably broad patent. Private line or other apparatus to be non-infringing must either use a battery call, or must have the magneto permanently in circuit, which would seem to be impracticable.

Another surprise to those who have not made a careful inspection of telephone patents will be to learn that the very idea of a switchboard and even of an ordinary telephone plug is patented. The patent covering these features is that of Charles A. Cheever, No. 208,463 of Oct. 1st, 1878. The claims are as follows:

> 1. In combination with a transmitting-telephone, a receiving telephone, a battery, and a signaling apparatus, a plug-switch having one side of the plug insulated, substantially as and for the purposes described.
>
> 2. The combination of the transmitting-telephones T, switchboard K, annunciator A, battery B, and receiving-telephones R, whereby a less number of receiving-telephones is used to receive messages from a greater number of transmitting-telephones, substantially as described.
>
> 3. The combination of a series of telephones connected with the switchboard K, which is provided with the spring-switches S, and receiving-telephones R and plugs P, when connected with the annunciator A, battery B, and return-wires, substantially as described, whereby the insertion of the plug P cuts out the annunciator and battery from the line through which the signal is to be received, but leaves the other lines intact, substantially as described.

As the growth of the telephone business during the current year will doubtless be more in the direction of private line and speaking-tube service, this patent is not of so great immediate importance as those previously referred to.

Those manufacturers and purchasers of telephone apparatus who propose to use several telephones in series on a line so arranged that a switch to the right or left will afford the desired connection in either direction, will be interested in the claims of the patent of T. B. Doolittle No. 209,115, of Oct. 22, 1878. They are:

> 1. In a district-telephone system, a series of switches, normally constituting portions of the main line, and adapted to sever the main line and complete a circuit from the earth at any station through either fragment of the broken main line on either side of said station, substantially as and for the purposes specified.
>
> 2. A district-telephone switch of conducting material, normally forming a portion of the main line and resting on two conducting-posts of the main line, and adapted to be swung about either of said posts, as centers, into contact with a metallic post having a ground connection, substantially as hereinbefore set forth.
>
> 3. The case I, provided with an alarm-bell and armature, a vibratory bar, and four cross-rods and wire connections, substantially as and for the purposes set forth.
>
> 4. In combination with the vibratory bar P and the cross-bars N N′, the bow-spring R, substantially as and for the purposes set forth.
>
> 5. The lever ends of the bar P, formed as described, in combination with the suspension-hook *f* and latch *g*, arranged to operate in the manner and for the purpose set forth.

It would seem that the judicious use of the metallic circuit would clear this interesting patent.

As to patents upon telephone switchboards and their circuits, a separate series of interminable articles would be necessary to convey any adequate idea of the careful and comprehensive manner in which the American Bell Company, through the Western Electric Company, have covered the subject. Any one contemplating the use of the simplest switchboard for telephone service, is advised to make or have made, a thorough and exhaustive search of switchboard patents before possibly laying himself open to litigation.

To give an idea, however, of how broad some of these patents are, it may be sufficient to refer to the following, covering the multiple switchboard: Patent of Leroy B. Firman, No. 283,334 of Aug. 14, 1883. Claims:

> 1. The combination of telephone-lines L and L^3 with connecting-plates A C, each provided with two plug-bales, the branch circuits, including annunciators 1 and 3, and switching apparatus, as described, whereby either of said annunciators may be included in the circuit of said telephone-lines when connected, as and for the purpose specified.
>
> 2. The combination of the telephone-lines with switches, one for each line upon the central-office switchboard, branch circuits, one branch circuit for each line, each branch including an annunciator and switching apparatus, whereby any two telephone-lines may be connected together through the annunciator of one of the lines, while the annunciator of the other line is not included in the circuit.

In connection with miscellaneous telephone patents, there is one of Thomas A. Watson upon an adjustable desk stand which is of interest.

The date of the patent is Sept. 28, 1880, and the number is 232,787. The first claim is:—

> 1. A telephone stand consisting of a telephone clamp or holder and a standard therefor, the said standard and holder being adjustable as to height and angular position to enable a telephone to be supported at any desired height and angle to suit the user, substantially as described.

It will be observed that if the desk stand be so arranged as to be adjustable as to angular position only, it does not infringe the patent.

One of the most encouraging signs of the times to the private line and speaking tube business, is the sale of telephone receivers outright by the Metropolitan Telephone and Telegraph Company of New York and other like concerns. The Bell company should unquestionably be able to make by far the best telephone receivers, through their ability, acquired by long practice, to produce a compound steel magnet of surpassing strength and durability.

Since January 30th, genuine Bell receivers have been on sale in various parts of the country. No transmitters, of course, or switching devices have been furnished. The price of receivers was first announced as $2.50 each, but it was soon reduced to $1.25 per instrument. The public is distinctly the gainer by the policy of the Bell Company in selling these superior instruments outright, whatever be the motive.

It would seem that the telephone patent situation is full of promise to those who propose to enter the business with a conscientious determination to respect every inventor's rights and to infringe no one's patents. It would also appear that the deliberate infringers are going to have a hard time of it. There are likely to appear two general classes of telephone manufacturers and dealers,—those who do not infringe switch and transmitter patents, or who honestly believe they do not, and those who propose to go ahead to suit themselves, respecting the rights of no one, and depending upon exaggerated and misleading statements to build up a business among innocent purchasers which will be sufficiently remunerative to take care of their own litigation, leaving the purchasers to take care of themselves.

If the new manufacturers of telephone apparatus will only be as careful and as conscientious in respecting existing telephone patents as are the American Bell Telephone Company, and the Western Electric Company, the future of the telephone business in this country will indeed be bright.

One or two vital points, not strictly within the patent purview, will be touched upon in a concluding article.

THE ELECTRO-MAGNET; or JOSEPH HENRY'S PLACE IN THE HISTORY OF THE ELECTRO-MAGNETIC TELEGRAPH.—VI.

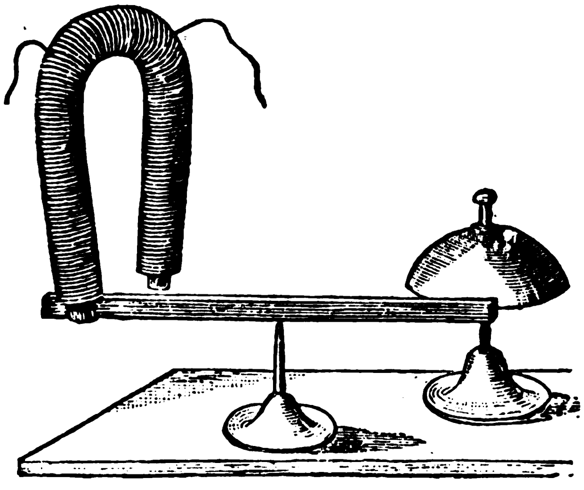
BY

Mary A. Henry

We have seen Henry making that circuit in which electricity was willing to act at a distance and discovering the reason why the great motive force was at last so complaisant after baffling the efforts of man for more than a century; we have seen him making that combination of magnet and battery which in fact constitutes the telegraph. "A number of other experiments," Henry says, "would have been made to verify this had not our use of the room been limited by its being required for public exercises."[1] These were the exercises of the exhibition or Commencement day of the Academy. When that day was over there was quiet in the empty rooms; a vacation of three weeks was before Henry—a delightful, free time to devote to scientific research.

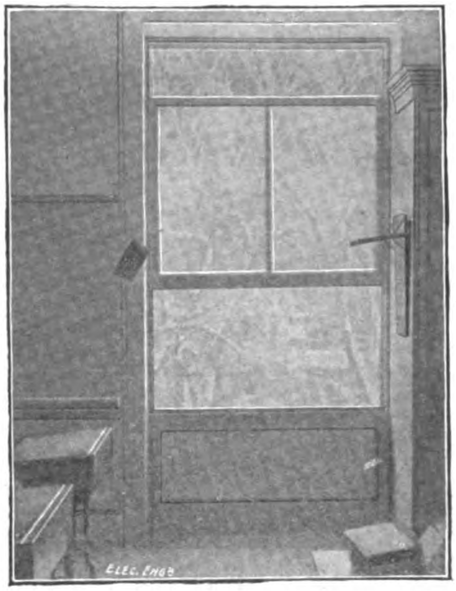
> "At the conclusion of the series of experiments," Henry says, "there were two applications of the electro-magnet in my mind: one the production of a machine to be moved by electro-magnetism, and the other the transmission of or calling into action power at a distance. The first was carried into execution in the construction of the machine described in *Silliman's Journal*, Vol. XX., 1831, and for the purpose of experimenting in regard to the second, I arranged, around one of the upper rooms of the Albany Academy, a wire of more than a mile in length, through which I was enabled to make signals by sounding a bell. The mechanical arrangement for effecting this object was simply a steel bar permanently magnetized, of about ten inches in length, supported on a pivot and placed with its north end between the two arms of a horse-shoe magnet. When the latter was excited by the current, the end of the bar thus placed was attracted by one arm of the horse-shoe and repelled by the other, and was thus caused to move in a horizontal plane and its further extremity to strike a bell suitably adjusted."

Surely it was another marked day in his life when Henry thus put to practical test the power of the circuit he had formed. We go back in imagination to see him make the trial. It is made in an upper room, the room appropriated to his use when he entered the Academy, his school room, lecture room and laboratory. His friend, Dr. Ten Eyck is his assistant. Around the wall passes the wire, a mile long. The battery is the same Cruikshank's trough, we saw him use on that memorable day in the long room.



Henry's Original Telegraph Apparatus.

The "intensity" magnet, if not the same, is of similar construction. In the recess of a window it is placed, and between its arms trembles the small steel magnet upon its pivot, while close at hand is the little bell. The magnet and battery are connected; the electric current begins; the mile of wire does not stop it; the iron horse-shoe wakes to life; the magnetic bar, ready to respond, springs to one pole, to strike with its free end the little bell; the bell rings. The telegraph has given its first signal. The first electro-magnetic telegraph is in existence.



The Starting Point of Henry's Original Telegraph Line.

(As we write these words we seem to hear a protest, and to see a finger pointed to some one or other of those telegraph efforts we have noticed in classes. We answer, perhaps with tedious repetition, those efforts, unable to surmount that great difficulty, the failure of the electric force, were not telegraphs in the sense that common use has given the term; they produced signals by means of electricity, which could be used to communicate intelligence, but they could not make these signals at any great distance. Henry, in the course of a few months had made the sensitive "intensity" magnet, the only intrument which could respond to electric influence at a distance; he had made the combination of magnet and battery, essential to the telegraph, and now, merging the discoverer in the inventor, he had made with that magnet and that combination, by the application of a mechanical contrivance, an apparatus capable of practical work. This telegraph in Henry's room, was not only the first, it was the first possible. It has been said it was not a telegraph, because it was not used commercially. Are our fingers not fingers, because we may not have used them for purposes of trade? This was an actual working telegraph, making sound signals exactly as the telegraph of to-day makes the sounds which give the telegraphic message; and later, in Princeton, Henry used the same arrangement in his philosophical hall to communicate with his wife in his residence, the wires stretching across the college grounds. But all this is a digression.)

Yes, the first telegraph in which there was no danger of the failure of the electric force was in existence. There was only a mile of wire around that room, but with no change in the principles there exhibited; in accordance with the laws there illustrated, that wire was to extend until it connected the Old World with the New, finding not even then a limit to the power of the electric current to act at a distance. We are told that a sound never is lost, that with the new phonetic instruments of the day, the falling stream may give back the words spoken near it, and what we say to-day may be repeated a century hence. There may come a time when history will be read by the ear, instead of the eye; when man may go back to the past, not to search in dusty archives, and among prejudiced records, but to wring from the air each sound that has broken it since it was first breathed by the human race; then this little bell will ring again and tell how and where this telegraph was born—the telegraph which could meet the long cherished desire for distant communication. It had made its first sound; there was its birthplace in that upper room of the Albany Academy, where the holes in the walls, only a few years ago showed where the wires were fastened. Do we say this was the birthplace of the telegraph? We must make here the distinction we have made elsewhere; the ringing of the bell was only one mode of using that combination of magnet and battery, which we have said really constitutes the telegraph. The long exhibition room, where that combination was first made, is the real birth place of the telegraph.

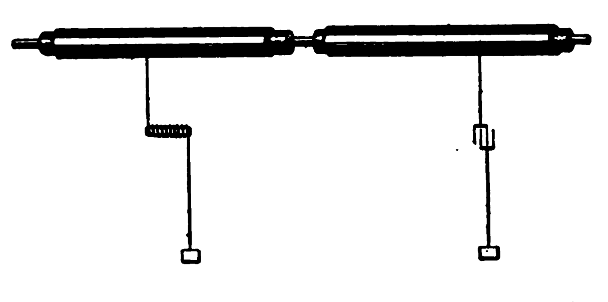
---

[1] Writings of Joseph Henry, vol. 1, p. 42, or *Silliman's Journal*, Jan. 1831, vol. XIX.

THE TESLA HIGH POTENTIAL CONDUCTOR.

In order to prevent loss by dissipation or interference by induction on line conductors carrying high potential alternating currents they have in some instances, such as at Deptford, London, been insulated and inclosed in a continuous conducting sheathing which is connected with the ground by a good conducting path.

While conducing to the safety of the system, Mr. Tesla has found that the use of a conducting sheath or screen around the line conductors and well grounded, or even brought into proximity to external conductors or large bodies is attended by an actual, and generally a serious, loss of energy which is the greater, the greater the number of alternations and the higher the potential. He therefore maintains the sheath either entirely isolated or connected directly or inductively to the ground, through a path which will practically prevent the passage of currents over it. He has also found that when a continuous isolated sheath or screen is employed, there is greater liability to loss of energy by inductive action; for, unless the sheath or screen be considerably shorter than the current waves passing in the conductor, electromotive forces will be set up between different points in the sheath, which will result in the passage between such points of induced currents. Mr. Tesla therefore, divides up the sheath or screen into short lengths, very much shorter than the wave lengths of the current used, so that the grounding of any one of such lengths or the approach thereto of a large body will result in an inappreciable loss, or at most a small local draining of the energy, while the tendency of currents to flow between different points in the sheath is effectually overcome. The function of the sheath as a static screen for preventing the dissipation of the electric energy, however, requires for its complete effectiveness an uninterrupted conducting partition or screen around the conductor. In the case of a sectional screen, this is obtained, by causing the ends of the insulated divisions or sections to overlap, and interposing insulating material between the overlapping portions.

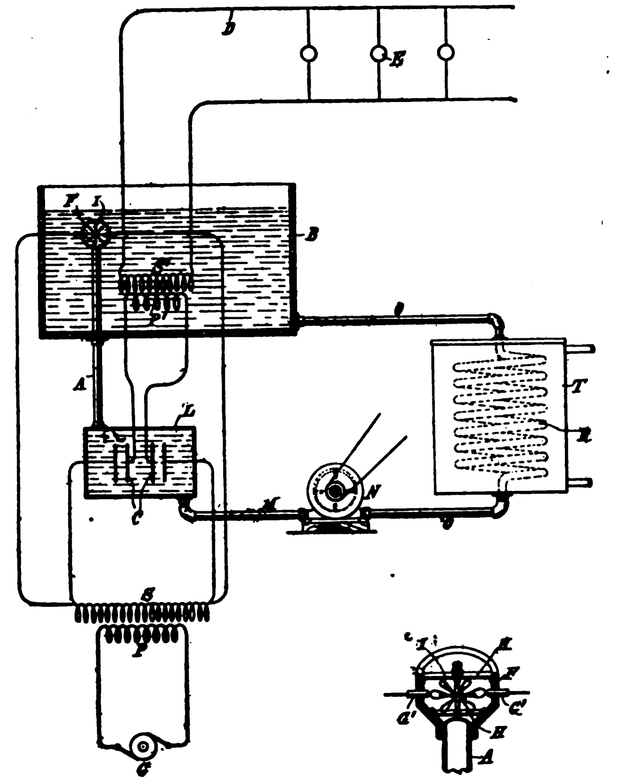


FIGS. 1 AND 2.—THE TESLA HIGH POTENTIAL CONDUCTOR.

For transmitting currents of very high potential and very high frequency, Mr. Tesla provides between the sheath and the ground a path of very high ohmic resistance, or one containing a self-induction coil properly determined with respect to the existing conditions so that it will effect the desired result, or a condenser of very small capacity, as shown in Fig. 1. In such cases the sheathing or screen for practical purposes may be regarded as isolated from the ground, since by the character of the connection employed no appreciable loss results from the passage of current from the sheath to the ground. Fig. 2 shows the construction of an actual conductor of embodying the idea.

TESLA'S AUTOMATIC FLUID INTERRUPTED FOR PRODUCING HIGH FREQUENCY CURRENTS.

The Tesla system of lighting and power transmission with high frequency and high potential currents, as is now well known, involves the maintenance of an intermittent or oscillatory discharge of a condenser or circuit of suitable capacity into a working circuit containing lamps or other devices. In systems of this character when the high frequency of the currents employed is due to the action of a disruptive or intermittent discharge across an air gap or break at some point of the circuit, Mr. Tesla has found it to be of advantage not only to destroy the least tendency to continuity of the arc, but to control the period of its re-establishment, and from investigations made with this object in view he has found that greatly improved results are secured by causing the discharge to take place in and through an insulating liquid, such as oil, and, instead of allowing the terminal points of the break to remain at a uniform distance from each other, to vary the distance by bringing them periodically in actual contact or sufficiently near to establish the discharge and then separating them, or what is the equivalent of this, throwing in and out of the gap or break a conducting bridge at predetermined intervals. To obtain the best results, moreover, Mr. Tesla finds it essential to maintain at the point of discharge a flow of the insulating medium, or, in general, such a circulation of the same as will constantly operate to cut off or break up the discharge as fast as it is established. The accomplishment of this latter result involves the employment of some mechanism for maintaining the flow or circulation of the insulating medium past the points of discharge, and he takes advantage of the presence of the same device to maintain the circulation of the insulating liquid in which the converter for raising the potential and the condenser plates are immersed; by this means the liquid is prevented from heating.



TESLA'S AUTOMATIC FLUID INTERRUPTER.

All this is accomplished by a pumping arrangement shown in Fig. 1, the spark gap being controlled by a small turbine which is shown enlarged in Fig. 2. When the pump is started up and the turbine I revolves, the blades bridge the space between the two terminals, nearly or quite touching the terminals in their movement. If now the tank B be filled with oil and the latter permitted to flow off through the tube A, the turbine will be rotated by the flow, the rate of rotation being dependent upon the rate of flow. By this means the arc or discharge is periodically established through a flow of oil, which secures in the most satisfactory manner the conditions best adapted for practical results. The flow of oil is regulated by the speed at which the pump N is driven, and by this means the period of re-establishment of the arc is controlled. A cooling tank T may be provided if necessary.

TELEGRAPHY AND TELEPHONY IN AMERICA.

Mr. W. H. Preece has recently read before the English Institution of Electrical Engineers a very interesting paper on his trip to this country last year. It is, in a sense, an appendix to his paper of 1884, which in turn took up the thread of a discourse delivered in 1878. In all these papers, Mr. Preece shows himself a keen, intelligent observer, a just critic, and one who is not prepared to condemn something novel simply on the ground that it has the misfortune not to be English. He is ready with hearty praise for what he thought good, and he came evidently to study rather than to scoff. There is of course much in the paper read last month that is familiar to Americans, but it is none the less an admirable epitome of the situation and the status of the electric arts in this country. Mr. Preece observed with care, lost no opportunity of seeing whatever was worthy inspection, and formed his opinions for himself. We may have occasion to refer to other points, but are now concerned chiefly with his remarks on the telegraphic and telephonic fields of work. His close touch with these in England makes his views on what is being done here the most interesting and suggestive part of his paper.

Summed up, Mr. Preece's statements embody an opinion on his part that telegraphy here is practically unprogressive and that telephony is making rapid strides; that England has nothing to learn from America in the use of the key but may gather many useful lessons as to the development of telephony. In fact, we have as much to learn, telegraphically, as the English have to learn telephonically. The inference is that the art of telegraphy here has crystallized, and a further inference, or corollary, would be that this condition was due to the existence of a virtual monopoly that does not keep pace with the times. This again would be a reflection on telegraphic management, but Mr. Preece is too courteous to indulge in that. Besides, may it not be possible that what we have ourselves heard an old expert telegrapher call "Western Union dry rot," is due to the fact that the telegraph has its very practical limitations, and cannot be pushed beyond a certain point? If that be so, the executive staffs of our telegraph companies may be sternly wise in keeping within narrow bounds and doing what they can there.

The telephone is to telegraphy what the incandescent lamp is to the arc light. The key and the arc have a necessarily limited sphere, while the telephone and the incandescent have a range so wide and universal that no frontier has yet been discovered for them. And this is true also of the technical side of the art, explaining why in telegraphy and arc lighting there is such little room for the engineer, while in telephony, as Mr. Preece notes, and in incandescent work, abundant opportunity is afforded for all the very best training and ingenuity that can be found. For this reason, we think, the telephone is even now dominating in the field of transmitting intelligence, and will at no distant date give further evidence of its inevitable mastery.

THE NIAGARA DISCUSSION.

In this issue we bring to a close the discussion on the memorable paper of Prof. Forbes describing the electrical features of the Niagara undertaking and embodying Prof.

Forbes' reply to his critics. Probably no electrical engineering work has ever been so variously criticized as this, and to that extent it is apparent that the authorities still differ widely on essential points in modern forms of electrical distribution. One fact is noteworthy, however, and that is, the almost entire absence of continuous current advocates. Had this paper been read five years ago it is safe to say that the greater part of the discussion would have been based upon the relative advantages of the continuous as against the alternating. As it is, the criticisms are confined almost exclusively to the question of periodicity and its effects and to details of construction. For the present, therefore, and until something more available is brought to the front, it may be considered that for great or even moderately long, distances, the alternating current is to be looked upon as the standard method. Notwithstanding the adverse comments of some of his critics, Prof. Forbes maintains the correctness of the views which led to the adoption of the system to be installed at Niagara and is willing to abide by the results of actual performance of the plant when finished. As a very few months will see the first dynamos at work it is but fair to suspend judgment until that period has arrived.

CONDUIT RAILWAY SYSTEMS.

The prize offered by the Metropolitan Railroad Company of New York, for a practical system for operating street railroad cars by underground electrical conduits has stimulated workers in this field to such an extent that in addition to the many such systems already proposed, we have almost daily brought to our attention some new method designed to fulfill the conditions imposed. It would be folly to deny that the problem is a hard one, but, on the other hand it would be very wide of the truth to say that it cannot be solved. The conditions to be met with are sufficiently well-known, and the question, therefore, resolves itself into providing the most simple means for fulfilling them. Evidently, one of the most important features of such a system, which must be considered, aside from mechanical strength and adaptability, is that of insulation, and those who have had experience with overhead circuits will appreciate the difficulties of maintaining a circuit carrying 500 volts in good working condition underground. If to this be added the further condition that the circuit shall be exposed at frequent intervals so as to make contact with a contact device carried on a passing car, the still greater difficulty of the problem would become apparent.

We have already described various methods which have been tried or proposed for accomplishing the results under discussion, and in this week's issue we publish a description of a system which embodies some features not heretofore used in connection with conduit railways, and which deserve more than passing attention. This system, known as the Munsie-Coles, carries out the principle that the base upon which the insulator is mounted shall be as well insulated as the conductor itself, and in order to carry out this design, use has been made of a particular form of insulator, designed to hold a drying agent, such as sulphuric acid. The practical results obtained with this system during an extended test at Hartford, Conn., would seem to make it well worth the attention of all interested in conduit electric railway work and we shall probably hear more of this system in the future.

EARNING DIVIDENDS.

However much dogmatism may still thrive in matters in which faith or belief alone is involved, it has no place in science or business, and hence we are led to call in question the rather sweeping statement made by Mr. W. N. Stewart in the paper on "Advantages of Direct Connected Direct Current Generators," printed on another page. After showing the benefits to be derived from the method described in the title of his paper, the author boldly asserts his belief "that it is the direct current stations that are paying the dividends." It is a pity that the author was not more specific in his statement, but we may fairly interpret his remark to mean that more dividend paying stations, proportionately, are to be found among the continuous current than among the alternating current stations. As the utterance is based merely on belief, it is perhaps not worth while to enter into an extended discussion upon so slight a foundation but the remark nevertheless is significant as showing the state of opinion, at least in some quarters. But if we examine into the origin of this belief a little closer we may perhaps discover the cause which has induced it. To begin with, it is not so very long ago that the standard method for operating both continuous and alternating current stations was by means of high speed engines belted directly to the dynamos or by slow speed engines and countershaft. While this system is still almost exclusively employed in alternating work, a distinct change has been wrought in the method of continuous current dynamo driving by the quite general introduction of direct connected engines. We do not doubt that by this means considerable economy has been effected in numerous continuous current stations that have heretofore employed belting and that to that extent at least they are in a better position to pay dividends. The "belief" of Mr. Stewart is probably traceable to his success with the more modern method. But we know of many stations of both types that are still employing the old methods that have been, and are still, paying dividends, and until we have more definite figures on the subject the statement of Mr. Stewart above quoted must stand as challenged. If Mr. Stewart's paper shows anything it is, that if alternating stations desire to hold their own with the continuous current they must, like the latter, come to direct connected driving. A beginning has already been made in this direction, and it is to be hoped that we shall see more such machines like the one installed at the Narragansett Electric Light Co.'s plant in Providence.

A Sign of The Times.

The trouble with the electrical business lately has been that there are too many receivers and not enough "transmitters;" but we see marked evidences of a return to normal and healthy conditions of activity. It is true that a great many electrical concerns have been treading the way of sorrow these many months, but trade is certainly on the mend, slow as the improvement may be. It affords us no little pleasure to note as one of the best signs of the time the recent reorganization of the Mather Company which was one of the first to feel the pressure of the common adversity and which is now one of the first to pull itself together for renewed work. It has enlisted capital and brains, and starts out on a new career with many a fervent wish for its prosperity. The courage and enterprise it has shown in springing to its feet again are most commendable and significant.

ELECTRIC TRANSPORTATION DEPARTMENT.

THE MUNSIE-COLES CONDUIT RAILWAY SYSTEM.

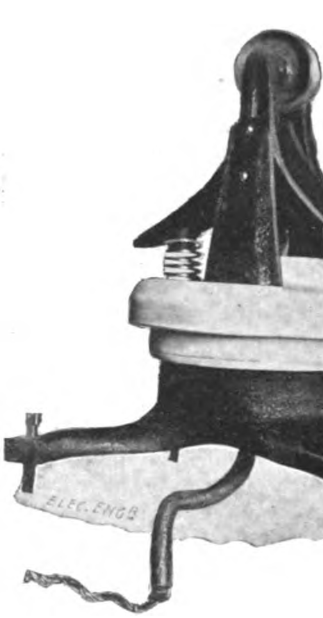

FIG. 1.—THE MUNSIE-COLES RAILWAY CONDUIT INSULATOR.

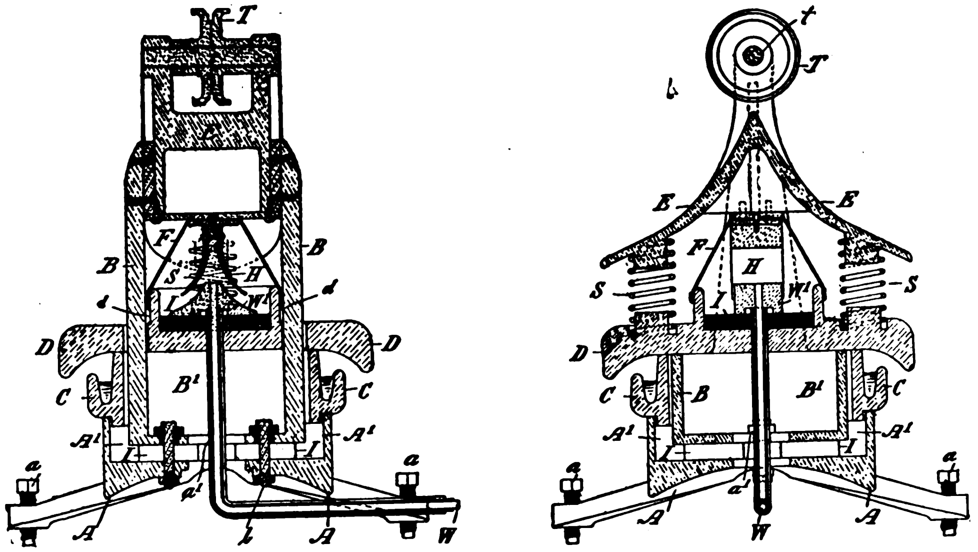
THE conviction is fast growing in electric railway circles that sooner or later the overhead trolley construction must give way to the conduit system, not only on account of the public demand for the removal of all overhead electrical construction, but because, in the opinion of those competent to judge, in the long run, a reliable underground system will be found to be more satisfactory and economical to operate, than an overhead. But, while this may be perfectly true, electric street railway companies cannot be blamed for exercising due caution and acting conservatively in the adoption of a system which must necessarily involve the expenditure of large sums of money and upon which their very existence depends. As a consequence the system which would seek favor must be shown to be practically operative, or, indeed, have been practically operated under all the conditions to which such a system is subjected. Among the few conduit systems which can be classed under the latter head is the "Munsie-Coles," surface contact system which was operated in Hartford, Conn., and of which an account was given by Mr. A. C. Shaw in THE ELECTRICAL ENGINEER, of May 17, 1893. The work of installation was begun in the fall of 1892 and the car was running in December, and was operated at different times every day except Sundays until September, 1893, without a single case of trouble in the circuit. No drainage was obtainable, as the city would not allow the tearing up and excavating of the streets outside of railroad tracks. The winter offered a severe test, on account of heavy storms of rain and snow with very cold weather. The insulators were often covered with water, slush and mud, but the circuit remained perfect and the car was run every day.

This was purely an experimental plant, but was found a valuable investment, as it enabled the Munsie-Coles Electric Railway Equipment Co. to perfect all their mechanical details of the apparatus and to establish a standard for permanent construction. Those improved details in every case were mechanical constructions on the insulator and surface contact-point box. The working circuit was on one of the railroad's regular lines, and their traffic was maintained without interference while the system was laid and worked. The result of the test was satisfactory in every respect, though performed under the most trying conditions in the Spring of 1893.

The operations at Hartford, though eminently satisfactory, nevertheless gave opportunity for further improvements, and we illustrate in this issue the latest form of insulator employed. This insulator is so constructed that, paradoxical as it may seem, it can be seated in the moist earth, and when the circuit is closed on it with everything covered with moisture, no leakage can take place, although the body of the insulator is made of iron and other metals to insure strength and life.

How these conditions can be fulfilled will be readily seen by a study of the accompanying engraving, Fig. 1, which shows the insulator in perspective, and Figs. 2 and 3, which give respectively a longitudinal and transverse section. A is the iron base hollowed out and running upward to the base of an annular piece of porcelain, C. B is the inner iron which is separated and spaced off from the base by a hard rubber block I and is bolted to it by bolts B B, which are insulated from B by rubber tubing shown as a piece of I. The circular formation of B is broken at the base of the porcelain overhang D, and runs up in two side pieces to the crosshead E, forming guides or slide bars for the crosshead E.



FIGS. 2 AND 3.—THE MUNSIE-COLES RAILWAY CONDUIT INSULATOR.

When the spur wire W is connected to W' on the hard rubber base I, the insulator is turned bottom up and liquid plastic insulation is poured in at A' which fills the space A' made between A and B to the base of C, and then up to the top of D. It also fills up the space B', thereby giving a solid body from the top of D to the bottom of A, at the same time thoroughly insulating B from A.

The efficiency of the plastic insulation is not affected either by contraction or expansion of the iron. After the work of filling the spaces has been done, the friction roller T and spring closer H with its soft rubber hermetic sealing cap F are all attached to the cross-head E. This being done E is connected up to slide up and down between B with F fastened on to the flange D so as to hermetically seal the circuit closer H and the live contact point W' and keep them clear of moisture, etc.

It will be seen by this that when the travelling contact bar on car shown in Fig. 4, mounts the friction roller T, it depresses the crosshead E in slides, which of course brings the circuit closer H in contact with live point W'. It can be readily seen that B with all its metallic contacts will be charged by current but the current cannot charge the base A unless by the outside surface of the porcelain overhang D and C. No moisture can ever lodge between the overhang and the concave space as the trough of the lower insulator C is charged with sulphuric acid which keeps the under part of the overhang bright and dry under every condition of moisture and dampness and consequently makes an absolute insulating brake between B and A. Flooding is not expected to take place, but if it should, water will not affect it any more than to give a slight leak for the time the flood lasts and only at the point where the circuit is closed, as the live point W' is sealed and protected by the cap F. As soon as the car passes the roller T, the spring S of the crosshead, Fig. 2, jumps back into position and makes the break in circuit between H and W'.

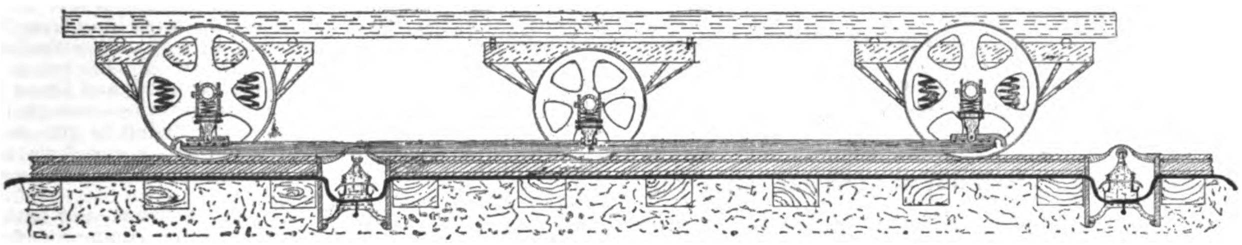


FIG. 4.—THE MUNSIE-COLES CONDUIT ELECTRIC RAILWAY SYSTEM.

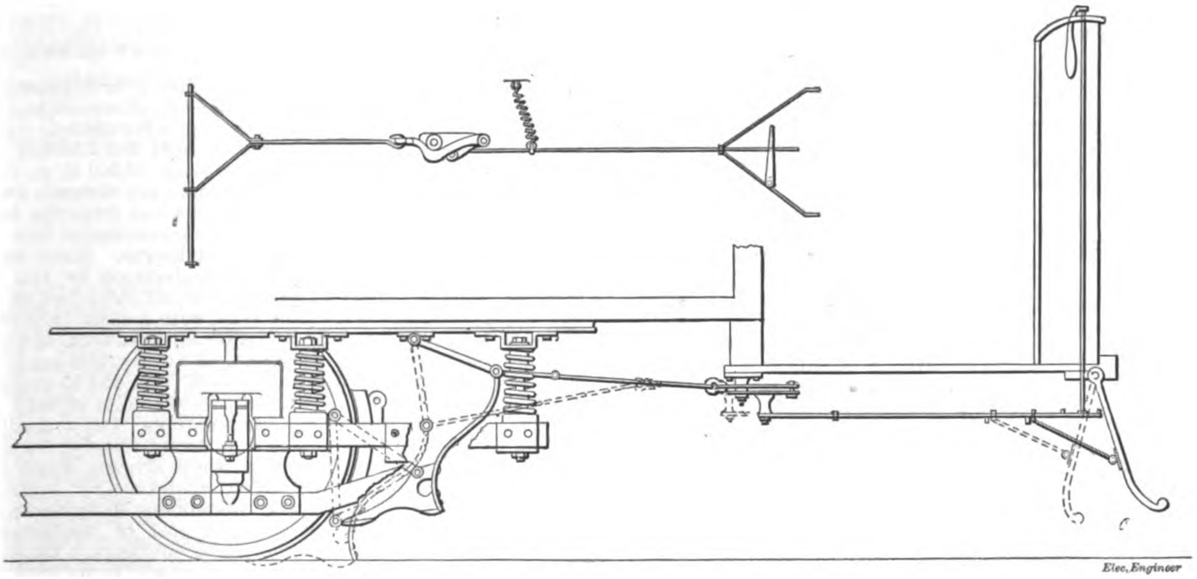
The sealing cap F and the annular porcelain chamber C with acid has been shown to be a most powerful practical working insulator, as it did under the severest test substantially everything claimed for it. The crosshead covers the spring S and sealing cap F and protects them from what little water may come through the slot in the surface plate. The corner bolts A are for the purpose of vertical and transverse adjustment of the insulator between bearing rails. The sulphuric acid requires renewing every two or three months, and one man can do two or three miles a day.



Elec. Engineer

AUTOMATIC CAR FENDER AND BRAKE.

It will also be noted that the system permits of the laying of a continuous, highly insulated cable to which the contact boxes are connected by flexible cable tops thoroughly insulated and lead-covered, so that the only exposed portion of the circuit is at the contact points. Another advantage of the system consists in the fact that no slot is required, so that the road way remains uninterrupted. The contact box, as will be seen, Fig 4, projects a short distance above the pavement and the bar attached to the car merely depresses the wheel to which the contact bar is attached and which completes connection between the live underground circuit and the motor on the car. After the car has passed, the contact is broken by the springs and the contact wheels are dead and can be handled with impunity.

The Munsie-Coles system is being exploited by the Munsie-Coles Electric Railway Equipment Co., of this city.

AUTOMATIC CAR FENDER AND BRAKE.

The first step in the improvement of any combination is the elimination of the uncertain human factor. In the improvement of the method of operating cars upon crowded streets so as to avoid accident, the public is not the element to be eliminated, certainly. While the public will benefit by "education" yet many injuries result from a lack of presence of mind on the part of the motorman, and a lack of adequate means of doing what should be done instantly and effectually.

The motorman can be "eliminated" so far as accident is concerned, only by some mechanical device which will automatically and at the proper time do all that the motorman can do,—stop the car. Such a device should cut off the source of power which propels the car, brake the car in the most effective manner and absolutely prevent anything from being crushed beneath the car. It should be simple in construction, always in working order, and inexpensive. All of these various requirements it has been attempted to meet in the device shown in the accompanying cut.

This device is operated automatically by pressure upon the hinged projecting fender, or by the motorman at will. Either method moves the rod under the car-platform, cuts off the current or releases the cable and swings the shoes down upon the track under the wheels, which run up slightly on the shoes, blocking the car. It is evidently impossible for anything to get under the wheels and it is equally evident that the car cannot be more effectually braked, practically, in any other manner, for the heavier the load, the more effective the braking, particularly if the under surface of the shoe is slightly roughened, and for this purpose the shoe may preferably be constructed so that the roughened surface bears upon any desired part of the rail to prevent excessive wear. The shoes on either side of the car may be connected with a light wire fender, to keep anything from getting under the body of the car, or, if preferred, the usual board fender may be fastened directly upon the shoes.

The mechanism at the point directly under the front of the body of the car where the rod running from the hinged fender connects with the rod running to the shoes is a simple lever, for the purpose of obtaining greater movement, and of throwing the weight of the shoes upon a dead centre, it being kept there by a slight spring. This arrangement keeps the shoes in their proper position when raised, offers a ready means for adjustment both as to the movement of parts and delicacy of action, and prevents any operation except in the manner appointed.

The shoes may be lowered, as already stated, or raised by the motorman by means of the lever upon the platform. The handle of this lever is hinged so as to drop into a slot to prevent it being turned accidentally, and this does not interfere with the operation by the hinged fender automatically.

It is not claimed that each distinct part of this device which is controlled by Mr. D. McFarlan Moore, of this city, is new; it was put forth simply as a combination of well known mechanical devices, for the accomplishment of obvious purposes, in an effective and inexpensive manner.

THE BALTIMORE AND WASHINGTON ELECTRIC RAILWAY.

WORK has been begun on the Baltimore and Washington Electric Railway, in which Messrs. P. A. B. Widener and W. L. Elkins, of the Philadelphia Traction Company, are interested. One track will be laid at first and turnouts used while the second track is being put down.

The electric line will be only 32 miles long, while the Baltimore and Ohio's steam road is 40 and that of the Pennsylvania 42 miles in length between the two cities. Entrance has been secured both in Baltimore and Washington, and connection will probably be had in the former city with the Edmondson avenue line of the Traction Company, which is to be converted into an electric railroad.

The estimate of cost of the Boulevard road is $3,000,000. The boulevard is to be 100 feet wide, and about one fourth of that width is to be occupied by the railroad tracks.

CANAL ELECTRICAL PROPULSION IN MARYLAND.

In regard to the use of electricity on canals in Maryland the report of mine inspector McMahan says:

"The use of electricity as a propelling power on the canal has been widely discussed, and from theory has been advanced to practicability. Maryland capitalists and coal operators have recognized the advantages to be derived from its introduction, and a company has been organized with a capital stock of $250,000 to introduce it on the canal. Mr. C. K. Lord, third vice-president of the B. & O. Company, is president of the new corporation, and in its directory are Lloyd Lowndes, H. Crawford Black, Alexander Shaw and J. Clarence Lane. This new method of transportation will greatly increase the output of coal from George's Creek region and will call for the employment of many more miners in our State. Not only will the mining region be benefited, but new life will be given to the towns and industries along the canal by opening up a new field of employment.

WESTERN ELECTRIC RAILWAY NOTES.

RICHMOND, IND. The electric railway line at Richmond, Ind., has passed into the hands of a receiver, who was appointed at the instance of the Union Trust Co. of St. Louis, Mo. The heavy expense recently incurred for improvements and the general depression of business are assigned as causes of the failure. About one year ago this line passed into the possession of Col. John F. Miller, superintendent of the Pennsylvania lines west of Pittsburg, and Russell Harrison, son of ex-President Harrison. The road is 11 miles long and has an equipment of 24 cars, of which 14 are motor cars.

AN INTERESTING FIGHT over the street railway franchise is going on in Indianapolis. The Citizens' Street Railway Company operates all the Indianapolis lines, 35 miles out of a total of 85 being equipped electrically. On January 18 the company's 30 year franchise, it is alleged, expired by limitation. Several months ago the city council prepared another 30-year franchise and sold it to the highest bidder. The old company did not bid for the new franchise, claiming that by virtue of an amended ordinance passed in 1880, but never formally accepted, the old franchise has yet seven years to run. Mayor Denny has called a council meeting to determine what to do. He says the Citizens' company will be notified to vacate the streets. The capital stock of the company is $1,500,000 and less than a year ago the property was sold to eastern capitalists at a high figure.

ST. JOSEPH, MO. A new electric railway is to be built this year at St. Joseph, Mich., to be known as the St. Joseph and Lake Shore Electric Railway. The capital stock of the company, just organized, is $75,000 and the officers are: C. P. Wright, president; J. S. Wolfe, vice-president; A. L. Thatcher, treasurer, all of Chicago; and S. C. Rosenberg of St. Joseph, secretary.

CHICAGO. A franchise has been granted to the Cicero and Proviso Street Railway Company, now operating an electric line in the city of Chicago, to lay two tracks on Chicago avenue from Robinson avenue west to Harlem avenue. The road is to be in operation within a year. Electric, horse or cable equipment may be used, but electricity will probably be employed.

THE NEW YORK-PHILADELPHIA ELECTRIC RAILWAY.

THERE now seems to be little doubt that a trolley line connecting New York and Philadelphia will actually be built in the near future. Within the last few weeks arrangements have been made to extend the New Jersey Traction Company's lines from Newark to Elizabeth and thence to Plainfield by way of Westfield avenue, the "county road," running parallel with, and but a stone's throw from the New Jersey Central Railroad, and hence passing through all the smaller towns whose travel has been exclusively controlled by the latter road. From Plainfield the road will probably be extended through Bound Brook and from there to New Brunswick, and thence through Princeton and Lawrenceville to Trenton.

This section will include the smaller towns now entirely dependent upon the Pennsylvania road for communication with each other and with the outer world.

The section of road between Trenton and Philadelphia is under the control of Col. Edward Morrell, of Philadelphia, who first conceived the idea, it is said, in order to provide a feeder for his steamboat line between that city and Bristol. He has purchased the right of way from the Philadelphia and Trenton Turnpike Company and organized two companies to operate the road, north and south of Bristol respectively. The first of these is known as the Bristol Railway Company and the second as the Holmburg Railway Company. It is promised that cars will be running on the road before next winter.

TRANSFERS IN CLEVELAND.

THE CLEVELAND CITY RAILWAY COMPANY, of Cleveland, having been much troubled by the fraudulent use of transfer checks, has adopted a new variety. It is larger than usual and the conductor in issuing it will be required to punch the month, day, hour and minute of issuance, the junction at which it is issued and the direction in which the passenger is going.

PROPOSED ELECTRICAL TRANSMISSION OF POWER IN INDIA.

SOME time ago Mr. Thomas Oddy, electrical engineer, of Rochdale, received instructions to prepare specifications and estimates for the utilization of waste water power for electric lighting and power purposes in Southern India, says the London *Electrical Engineer*. The project was to transmit 12,000 h. p. from some extensive waterfalls to two large towns some distance away. The towns in question are so far apart and away from the falls that it will necessitate a cross-country power transmission line (poles and conductors) being laid, 110 miles in length. Some idea of the magnitude of the scheme will be understood by the following abstract from Mr. Oddy's report: 3,000,000 cubic feet of water per minute is precipitated over the falls, with a clear drop of 200 feet; 12 1,000-h. p. turbines will be required, 12 towers, 10 bridges, 144 alternators, motors and dynamos, of an average capacity of 250 h. p. each; telephonic communication from end to end and at five intermediate stations; 3,300 poles; 24,000 miles of wire made into cables; two large central-station buildings; two transformer stations; 96 transformers of 250 h. p. each; massive switchboards, weirs, flumes, sluices, etc. The whole scheme when completed will cost £350,000. After making allowance for interest on this loan, paying £10,000 as a yearly instalment to decrease loan, paying working expenses, inclusive of cost of maintenance, and depreciation of plant, machinery and buildings, a profit of £7,000 per annum is anticipated. The current will be utilized for power and lighting purposes in cotton mills, corn and rice mills, for domestic purposes, in machine shops, for pumping, working cranes, hoists, mineral-mining and coal-cutting, haulage of canal tug-boats, tramways, and various other purposes. Mr. Oddy is now also engaged on a similar scheme for some public authorities in Southern Russia. This project is for transmission of 5,000 h. p. a distance of 98 miles.

ELECTRICAL GOODS IN WALES.

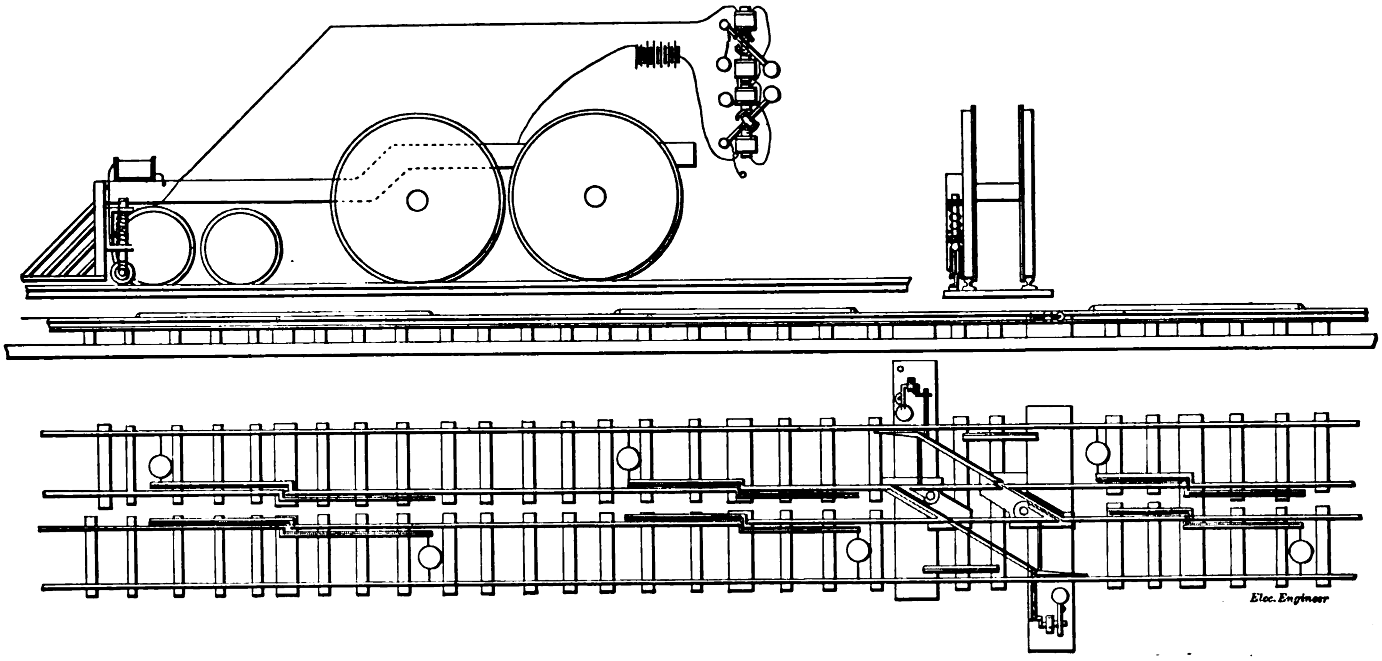
Mr. John J. Willetts, 30 Ryder street, Cardiff, Wales, vice and deputy U. S. Consul, is desirous of securing the agency for American standard electrical apparatus in the Principality.

MISCELLANEOUS.

THE SHEEHY ELECTRIC BLOCK SIGNAL.

Since the recent fatal disaster on the Delaware, Lackawana & Western Railroad the company have been forced to consider some form of block signal system. It seems incredible that a road of this size and importance should have been so long permitted to depend wholly upon the vigilance of its conductors and the sprinting powers of its rear brakemen to prevent rear end collisions; and events now show that beside the loss of life, traceable directly to the lack of modern improvements, the criminal parsimony of the company will result in the loss of a sum of money probably quite sufficent to have avoided the horror had it been expended for some practical block system instead of in the payment of damages.

Among the systems submitted for examination is one devised some years ago by Mr. R. J. Sheehy, of 44 Broad street, this city —an automatic electric signal indicating upon semaphores in the engine cab the condition of the road ahead, whether another another train, a misplaced switch, a broken rail or an open drawbridge prevents further progress or demands caution. The accompanying diagram will explain the system. The tracks are divided into independent blocks, one rail having its sections bonded throughout its entire length, and the other throughout the length of each block and insulated from the next. At the further end of each block the two rails of the track are cross-connected through a permanent resistance embedded in the ground. A contact plate of angle iron a little higher than the track is attached to the other end of the "block" rail (so called here to distinguish it from the continuous rail) and extends back a thousand feet or more into the preceeding block. A similar plate may extend from the forward end into the section ahead, as shown. This when used would be on the opposite side of the rail and is for use in case a train is compelled to back again into a block it has once cleared.



The Sheehy Electric Block Signal System.

On the locomotive is the contact device carried on the frame, but insulated from it and pressed downward by a strong spring, while in the cab are two visual signals and a battery. An artificial resistance is also provided exactly equal to that of the track circuit on any block. It may be mentioned that no matter what the length of any one block may be, the resistances of all are made alike by the coils embedded between the tracks. When the contact arms are resting upon their stops the circuit is, then, from the battery through the semaphores, the resistance and back to the battery, the semaphores both showing safety signals When the contact wheel runs upon the angle iron plate connected with the next block the arm is raised and the circuit is broken at the stops, cutting out the resistance upon the locomotive and instantly substituting that of the track. If the line ahead be clear, therefore, no change will occur in either semaphore. If, however, the circuit ahead should be broken, by reason of a broken rail, a misplaced switch or an open draw, the semaphore indicating "incomplete track" would fall, as it is arranged to do on the cutting out of the current. Should a train be on the block it would short circuit the permanent resistance at the further end and send an excess of current through the instrument actuating the "block occupied" semaphore.

The whole system is thus always before the eyes of the locomotive engineer and neither fog, darkness or smoke can hide his signals from view. The whole system is thoroughly automatic and the cost, both initial and for maintenance, is said to be much lower than that of any existing practical system.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.—IX.—(*Concluded.*)

BY PROF. GEORGE FORBES.

(*Discussion.*)

Prof. Forbes said he had to congratulate them on the fact that that evening's discussion had somewhat redeemed the character of the Institution. Those who had really studied this problem to some extent, who knew what the difficulties were, and where the pitfalls were, must have felt that some of the gentlemen who took part in the discussion on the first night had not even begun to grasp the character of the problem before them. He himself had felt nothing but sorrow for the position of that Institution in having such speeches made on a matter of so much importance. That evening there had been more appreciation shown of the difficulties of the work and of its character generally, and the discussion had been carried on with less show of ignorance. In the discordant views expressed by the various speakers he saw a reflection of the train of reasoning which had been going on in his mind during the years he had devoted to the subject, and he saw the beginning of the workings of the minds of those who would have arrived at different conclusions if they had had longer to think about the matter. He was astonished at the manner in which the question of low frequency had been received. He did not claim for himself one atom of credit for having, after most careful consideration, arrived at the conclusion that the lower the frequency they got in the design of their dynamo the better would it be for the working; but now, after the remarks that had been made, he began to look upon himself almost as if he was the discoverer of low frequency. Before going on to discuss the different speeches, he wished to say a few words on a subject which Mr. Ferranti had brought forward, and which had also been alluded to in the technical press. It had been said that the International Commission was a farce, and that those who prepared schemes had been treated unfairly. Mr. Siemens had in a great measure answered this, and he would not delay them by referring to that part of the subject. But it had been said that it was determined to give to the men who furnished the plans which should be adopted the superintendence of the work. He held in his hands a report which he submitted at the time, in which he said that alternating current was to be used, that it was to be of two phases, that 2,000 volts was to be used for the local work, and that step-up transformers were to be used to carry it to Buffalo, that the motors were to be synchronizing motors, Tesla motors with two phases, and motors with laminated fields and commutators. The International Commission had been absolutely loyal to their compact in giving him the superintendence of this work. The only serious mistake which he made in that report was to recommend the adoption of the Mordey alternators. They knew now that they were not of the right frequency and that in certain other points they would not suit their purpose. If the discussion had been barren in certain parts, they had at least heard from Dr. Fleming of the methods used at Deptford to overcome electrical resonance and that was an important point. The endorsement which Dr. Fleming had given to his views he considered to be of great value, and showed that he given some attention to the subject. When he said that the lines should never be suddenly connected to or disconnected from, the machine, he said something which other speakers probably considered might be regarded as an axiom. But although it might be the practice in this country, it was absolutely the contrary to the practice in America. Accustomed as Mr. Mordey was to deal only with comparatively small electric-lighting plants, he did not realize what their scheme was to be, and especially he did not realize that theirs was to be a power-distributing plant, and that the electric lighting that was to be done was utterly insignificant compared with the rest of the work. Mr. Mordey's opinion that he (Prof. Forbes) had thrown down the gauntlet to electric-lighting men showed that he did not realize the nature of the problem; his reference to transformers of small horse power as being applicable to their case also showed it; his willingness to condemn the artificial load on the ground of expense also showed it. With regard to parallel working, Mr. Mordey argued, if 100 periods succeeded, why go down to 25? He (Prof. Forbes) had shown twenty reasons for going down below that. It was true 100 periods would allow of the machines working in parallel without getting out of step. But they wanted more than that; they wanted them to run in step without waste current passing from one to the other, and without breakdown. He did not consider that 100 periods would succeed so well as Mr. Mordey would lead them to believe. Mr. Mordey knew quite well that while his alternator worked nicely in parallel it did not work perfectly; he knew his machine had broken down at times. They at Niagara could not afford to experience such breakdowns as he had met with in his comparatively small machines. Mr. Mordey's alternator did not work well enough for their purpose. He said, before deciding whether to adopt it or not, tests must be made with high resistance between the dynamos in parallel. Mr. Mordey put in a group of Sunbeam lamps in series. The lamps went up and down with a periodicity of a few seconds. From the moment of those experiments he (Prof. Forbes) felt that the machines were not suitable for their purpose. Mr. Mordey thought artificial loads would introduce greater dangers. He had been utterly unable to see what those dangers were. All he claimed for the artificial load was that it was a help to keep the system from breakdown. They could not afford to have breakdowns. He looked to every possible safeguard that could be devised, even though the expense were something greater. In this case there was no additional expense, because the artificial load when not being used for that purpose was useful for other purposes. Mr. Mordey's remarks about skin resistance would be accurate if they could subdivide the 36 square inches required for the conductors of the first 15,000 H. P. used at 2,000 volts. But they could not get space for the enormous conductors unless they massed them together, and at high frequencies the skin effect would come in. Mr. Mordey's remarks on transformers caused him the most regret, for they showed him how far he was from grasping the problem. He did not appear to realize the work that must be done by consulting engineers. An engineer was very little likely to advise such a scheme until he had every detail worked out to a very large extent. Foreseeing difficulties with manufacturers, he set to work to design transformers of low frequencies for every kind of work for which they wanted them. Designing transformers for special cases and for larger sizes than usual was somewhat laborious work, but the results were quite certain when they knew the quality of iron used. Efficiency was so high as to be of almost no account at all when dealing with the large sizes which they required for their work. With regard to the question of the electromotive force of the dynamos, he really hardly understood Mr. Mordey, who wanted them to use 500 volts. If Mr. Mordey would estimate the section of copper for 50,000 H. P. or so, he would see the difficulties to be met with. That copper section would be about 400 square inches. He had no doubt Mr. Mordey had never realized that until that moment. He could quite understand that with Mr. Mordey's type of machine it would not do to go above 2,000 volts. But he was surprised that Mr. Mordey was not able to realize these two facts: first, that with a 5,000 H. P. the space taken up by insulation was quite immaterial, and in the second place that if you shirked the difficulty of insulating to 20,000 in the fixed armature of the dynamo you would have to face it when you came to the fixed transformer. Mr. Mordey's remarks on lighting were quite beside the mark. Theirs was not a lighting station. Mr. Kapp had dealt with the relative efficiency of single, alternating, two-phase and three-phase currents, and quoted Prof. Elihu Thomson's views. Prof. Elihu Thomson had submitted to him the whole of his reasons for his statement, and he examined them most carefully, and found that they owed their error to the common American mistake of estimating the size of the conductor by the amount of drop they were going to allow instead of by Lord Kelvin's law of economical section. Mr. Kapp admitted his (Prof. Forbes') proof that the losses in the field of a multiphase motor were increased 42 per cent. in the case of a particular motor when they doubled the frequency, but he claimed that a machine with twice the number of poles running at the same speed gave 2¼ times the power. Had it not been Mr. Kapp who said that, he would have taken no notice of it. But in both of them they had the same total number of lines of force rotating with the same velocity round and round the armature, generating the same electromotive force in the armature and the same current. There was no difference whatever in the power developed in those two machines, and the 42 per cent. remained as he (Prof. Forbes) had given it. Mr. Kapp said they could not find space to put rings on to a direct-current motor to convert it into a synchronizing motor, He (Prof. Forbes) did that last summer with one of the stock machines supplied by the Westinghouse Company. Mr. Kapp said he did not know how he would start that motor. The motor would only require to be started once in several months, yet he had started it without recourse to Tesla motors. Mr. Kapp said he had objections to low frequencies with motors, but he did not give his reasons. He heartily thanked Mr. Kapp for the way in which he spoke of his (Prof. Forbes') machine; he was exceedingly glad that a man of such eminence in designing as Mr. Kapp had spoken so well of the machine. He need hardly say that if he dreamt that the Cataract Construction Company were acting in any unfair way he should cease to be connected with the work. Mr. Ferranti had been good enough to tell them that he had stolen the machine from Mr. C. E. L. Brown. Mr. Brown said it was the worst possible design that could have been devised. He knew it was simply a ridiculous assertion that the design of that machine could be said to be in any sense like that of Mr. Brown; but he was glad to be able so promptly to bring a quotation from Mr. Brown to show that he did not think so. He believed his (Prof. Forbes') machine was the first which had been designed upon a principle which ought always to rule the design of a large machine of a new type of construction where they had not past experience to go upon, and that was that they should reach the most economical efficiency. In this design he had added material until he reached a point at which $60 worth of material did not save 1 H. P. He had found, as the result of experience in trying parallel running with different types and a certain number of different frequencies, that lowering the frequency increased the efficiency, and not only the ease, of parallel working. With regard, further, to Mr. Ferranti's remarks, he denied *in toto* that any person had the right to say that the design of that machine had a plausible resemblance to the design of any machine that was put before the Company. He was seeking to get the best design he possibly could, and in so doing it so happened that he differentiated that machine from any one of those sent in infinitely more than they differentiated amongst themselves. Mr. Ferranti said he was wrong in saying that 20,000 volts completely insulated was so very good. He (Mr. Ferranti) thought 10,000 volts with one pole to ground was better. He gave as his reason that with the 20,000 volts, if one conductor was put to ground, the whole insulation was reduced to 10,000 volts. Yet he admitted that he had one of his own conductors to ground; suppose the other got put to ground by any means, how many volts insulation would that be reduced to? It might be that by using concentric cables they avoided the chances very much of putting the other one to ground, but there were connections and numbers of other means by which it could be put to ground far more likely when hidden underground than in the subway. They owed some gratitude also to Mr. Evershed for working out the back electromotive force due to the inductive action of the conductors, and for showing them how valuable low frequency was for that reason. Mr. Crompton complained that he had not given the cost. Mr. Crompton might be perfectly sure that when they knew the actual cost down to a penny he would not give him the cost then either. There were some things he could not tell them, but he did not think the Institution had any right to complain of his not having been candid enough. The result of the discussion upon his mind had been, first, astonishment to find that he was a discoverer instead of a plain, straightforward plodder; and in the next place he was impressed by the vast differences of opinion expressed by different members of the Institution. He felt a good deal fortified in all the conclusions he had arrived at by the general result of the criticisms, however opposed to his views they might have appeared to be. It might be premature for him to say so, but he felt now that all those who had entered into the discussion would, with further study of the subject, ultimately arrive at his position. Meanwhile he thanked them heartily for the expression of their opinions; he appreciated their motives, and he appreciated the value of what had been said by some of them. At the same time he could assure them that he had not lost one particle of confidence in the perfect success of the work that was being carried out; in fact, his own opinions had been strongly confirmed by the general result of the discussion.

The PRESIDENT said although the hour was very late he was certain they would not wish to close that meeting and the session without conveying to Prof. Forbes their deep thanks to him for having brought that subject before them, and for having elicited such an important discussion. They had evidence before them that night of Prof. Forbes's enthusiasm and his nervousness, or rather his suppressed anger every now and then had kept him from that fluent defence of his position of which they were more familiar. He was quite certain that if any one of them had worked for years on a tremendous undertaking like that of Niagara, and had been as severely handled as Prof. Forbes had been, they would not have remained as cool as he had.

ADVANTAGES OF DIRECT CONNECTED DIRECT CURRENT GENERATORS.[1]

BY W. N. STEWART.

For a model generating plant of 500 h. p. the following apparatus should be installed: One multipolar generator of 100 h. p., running at about 250 revolutions per minute, directly connected to a compound engine of the same speed. One multipolar generator of 400 h. p., running at about 170 revolutions per minute, directly connected to a compound engine of the same speed. In most cases condensing apparatus is to be used where water is available. These dynamos are to be made for 220 volts if the 3-wire system is used, and for 480 volts if the 5-wire system is employed; 3 wire distribution to be employed where the distances are not over one mile from the power house, and five-wire where they exceed one mile.

Additional apparatus as follows would be necessary: for 3-wire system, 120 cells of storage battery, each cell having a capacity of 30 amperes for fifteen hours; for 5-wire system, 240 cells of battery, same size. This storage plant to be used as an equalizer and regulator, and to furnish current during the day. Necessary switchboard apparatus, including an automatic regulator for dynamos, would also be necessary.

The wiring would be as follows: one circuit of mains and feeders for commercial and house lighting. This would supply all private consumers with arc or incandescent lighting or motive power; each customer to have a meter. All motors to be connected to the outside wires of either three or five-wire system.

To operate this plant we would employ but two men—one engineer and one fireman. The station would have a superintendent and lamp trimmers as necessary for the number of arc lamps used. The public arc lamps would be wired as follows: if 3-wire system is used, a common neutral wire would be supplied for both public and private lights: this neutral being thoroughly grounded at various points. Thus but two wires would be run for the public lighting; the arc lamps being connected in groups of two between the positive and neutral. If the 5-wire system is used, the arc lamps would be run in groups of eight, each lamp having an automatic cut-out. To run arc lamps on a constant potential circuit it is necessary to have a certain amount of resistance in the circuit to steady the arc; this resistance should be in the line wire, iron wire being used in some cases, or copper wire not smaller than No. 8.

Technical men may say that this is a waste of power, but the author thinks this loss in resistance is overrated.

If the ordinary arc dynamo gives 78 per cent efficiency and the constant potential machine 95 per cent., we have a difference of 17 per cent. in favor of the constant potential machine. The resistance necessary to work the low tension arc lamps never absorbs more than 15 per cent. of the current, so that we have an advantage of 2 per cent. in favor of the system which I am describing.

But we have still another gain: the ordinary arc dynamo runs at about 900 revolutions per minute and must therefore be belted to the engine. The friction of this belting and high speed dynamo must be taken into consideration. If one belt direct from the engine is used, 10 per cent. is lost; if a counter-shaft is used, 18 per cent. is lost. So that is one case where we gain 12 per cent. in our power bill, and in the other 20 per cent. And this is not theory; it is being done every day in the State of Wisconsin, and adjoining states.

The operation of such a station would be as follows: The small dynamo would be started no later than four o'clock in the afternoon, most of its current being absorbed by the storage battery; as darkness approaches, the large dynamo would be started, its current being divided between the customers, streets and storage battery, until all the lights are burning, when the battery would simply act as a regulator. This engine would run steadily until 2 o'clock in the morning, the last four hours being principally devoted to charging the battery. Thus the employees would have a daily run of 10 hours, and the engines would always work at maximum efficiency for the full run. The battery would do the work 14 hours daily. It may be well to state here that storage batteries are now being used in most European stations, and in three or four of the largest American stations with good results, and that batteries can be had which infringe no patents, and which are thoroughly reliable in their action.

We have a station which is made up as follows: One machine in operation at one time, doing all our work, that machine having an efficiency of 95 per cent. with no losses in belting or shafting, running at slow speed with consequent minimum of cost for repairs. A daily run of only 10 hours, thus getting the best possible service from employees. Current available day and night for all persons. A machine which does not burn out, and which can be repaired in three hours. Low pressure wiring, therefore no damage suits for loss of ife. Longer life and less blackening of incandescent lamps, as the battery gives a current absolutely uniform at all times. Less real estate and buildings required. Less liability to breakdowns. No burned-out armatures. The average cost of burned-out armatures on arc machines in 77 cities was last year $2.14 per arc lamp. Less oil; fewer employees; no losses in transformers, or other subsidiary apparatus.

The author asserted that an economy of 40 per cent. could be thus obtained over the old-fashioned methods, and cited several instances of existing plants to substantiate his statement. In conclusion, he said that facts, as observed by him in this country and Europe, lead him to reiterate his belief founded on 23 years' work in the electrical business, that it is the direct current stations which are paying the dividends.

CORLISS COMPOUND ENGINES FOR ELECTRIC LIGHT WORK.[1]

BY E. L. DEBELL.

WITHOUT attempting comparisons with any other types I will endeavor to give the conclusions arrived at from the use of Corliss engines in our plant at Sheboygan, leaving each of you who is interested to compare them with results or knowledge obtained of the other types. In our plant we have been running steadily for the past 15 months a Corliss cross-compound, 24 x 28 high pressure cylinder, 46 inch diameter low pressure, speed 74 revolutions per minute, rated capacity about 650 h. p.

We use a syphon condenser, supplied by a duplex pump with two 18 inch steam, and two 12 inch water cylinders, 12 inch stroke.

We carry constantly 25 inches of vacuum, which, however, can be readily increased to 28 inches should the load be very heavy. When the load is light we consider it the best practice to keep it at 25 inches and reduce the steam pressure.

A good Corliss engine of this size and type should handle its rated economical load on 18 pounds of water evaporated per horse power hour and within a range of 20 per cent. above or below that point on not over half a pound additional. With good boilers properly fired, and allowing 7½ pounds of water evaporated per pound of coal this would equal 2.4 pounds of coal per horse power hour.

It should be borne in mind at this point that while the first cost is higher for an engine capable of running the least coal, it is really cheaper in the end, as less investment is required for boilers, and the saving in coal continues for all time.

The first cost of the Corliss engine may be placed at one-third more than an equally well made one of the high speed type, and it takes up about one-third more room. Its life however is generally conceded to be 50 per cent. longer, on account of larger wearing surfaces and slow speed. The greater bulk is usually of no serious moment, except where space is restricted or valuable. The cost of attendance and oil and waste is practically the same as on any other good engine, while the cost and facility of making repairs seems to be in their favor.

Another feature of the Corliss engine is that trouble usually develops slowly, in most cases giving warning of its existence in time to apply the proper remedy before it becomes serious, sometimes saving a shut-down of more or less duration.

The selection of proper sizes is a very important consideration as the addition of an extra cylinder reduces the range of economy. The load in nearly every electric light plant is so variable that one engine cannot do the work properly, and it is probable that in most cases three engines of one size will give the best results. They should be large enough so that one will handle the light load, two of them the heavy load, leaving one always in reserve. This gives an economical size for all the varying loads, and practically duplicates the plant with a minimum expenditure in idle machinery. The cost of the three engines will not be very much greater than the same capacity in one or two engines, and some less boiler capacity will be required.

As to close regulation and steady motion, no trouble should be had on this score, if the power machinery is properly installed and managed, and the engines worked within their economical range.

The proper appliances should be used both in the engine and boiler rooms to ascertain if the benefits paid for are being secured, and if not, where the leak is. If more fuel is being consumed than seems necessary, examine the engines, and if they are working properly ascertain how much coal the boilers are consuming per pound of water evaporated. The trouble will most likely be found in one of these quarters, and when remedied good results will surely follow.

---

[1] Abstract of a paper read before the Northwestern Electrical Association, January 17, 1894.

SOME PERSONAL REMINISCENCES OF HEINRICH HERTZ.

The first days of the new year have brought with them a mournful message which could only be received with deepest sorrow in all countries where science has found a home and the work of its representatives meets with adequate understanding. Heinrich Hertz, the celebrated physicist, has, after a short but brilliant career, closed his eyes forever, and a life bright with powerful and fertile energy, and unfolding the most splendid prospects, has sunk into an early grave. The grief which the news excited in Germany, his native country, meets with a loud echo in all parts of the world where the weight of the loss is fully understood and the merits of the deceased have found deserved appreciation. Deeper it must be with all those who have learned, by personal experience, to admire besides his eminent talents the noble and amiable disposition of his mind.

Heinrich Rudolph Hertz originated from a prominent family in the city of Hamburg, where he was born on the 22d of February, 1857. After finishing the preparartory course for the university, he first devoted himself to the study of civil engineering at the Polytechnic School of Berlin, where at the same time he served his military term in the Imperial Railway Regiment.

More and more he felt an imperative attraction towards abstract scientific investigation. He consequently resolved to make physical research his special branch and pursued this line of study in the Universities of Munich and Berlin. The solution of a prize theme proposed for competition by the University of Berlin, in 1878, offered him a welcome inducement for a first trial of his ability for original scientific research. The problem was to determine by experiments in induction an upper limit of the kinetic energy of the electric current. A gold medal tendered with the most flattering comment on the cleverness and originality of the solution presented, rewarded Hertz for this first effort in scientific production.

The time of recreation offered by the ensuing Michaelmas vacations of 1879, brought out the second fruit of the work of the young scientist, this time purely mathematical in character. His treatise on "Inductions in Rotating Spheres" immediately placed him in the ranks of the most competent mathematical philosophers. He made it the basis of his application for the degree of Ph. D. Professors Helmholtz and Kirchhoff, his examiners, gave their official verdict on the dissertations, pronouncing it as "Doctrinae et acuminis specimen laudabile," a rare distinction from the tribunal of these authorities.

A short time thereafter, Prof. Helmholtz selected Hertz as his assistant in the Physical Laboratory of the University of Berlin, while at the same time he became a member of the "Physikalische Gesellschaft," the renowned society which embraces the most prominent German workers in physical research.

The period which Hertz spent in the quiet palace of the Physical Institute bore ample witness to the fertility of his mind in the most diversified branches of his favorite science. We find him equally engaged on problems in the provinces of elasticity, hydro-dynamics, heat and meteorology, the great majority of his researches however belonging to the department of electricity. Several practical instruments devised at this time illustrate the inventive disposition of his mind which is characterized in every instance by the originality and simplicity of the means employed.

The power of Hertz's judgment and his eminent mathematical talent soon secured him a prominent position in the estimation of the members of the Physical Society, and when in 1883 the University of Kiel inquired for a competent "Docent" on mathematical physics, and Hertz was selected for the position, the impression that the choice was the proper one was unanimous. Great satisfaction prevailed when, two years later, his superior merits were rewarded by the honors of a full professorship, the Government of Baden calling Hertz to the chair of physics in the Polytechnic School of Karlsruhe.

Here it was that Hertz carried out the celebrated investigation which gave him international fame and made him the centre of admiring attention throughout the scientific world. Decades had elapsed since by Maxwell's famous treatise the brightest prospects were opened for establishing a new and solid bridge between the departments of electricity and of light. Hundreds of the most able minds, thoroughly convinced of the intrinsic truth of the theory, were looking for means of its experimental verification, when Hertz presented the conclusive proof of the identity of optical and electrodynamic waves as the mature fruit of his wonderful and exhaustive researches.

In close succession the papers illustrating his systematic course of investigation followed each other. Starting with the development of the proper instruments of observation, keenly perceiving and clearly interpreting even the most minute and obscure indications of the same he soon proceeded to the application for the grand problem which they were destined to solve. Early in 1888 he was able to lay before the scientific world conclusive evidence of the finite velocity of the propagation of electrodynamic waves and of their close relationship to light waves. A few months later the full triumph of Maxwell's theory was established in every detail by exhaustive and overwhelming experimental proof.

One cannot read the series of papers embodying these researches, which soon created a sensation throughout the scientific fraternity, without deeply admiring, besides the rich fruit harvested at every step, the divining mind which is never misled by any complexity or obscurity of facts. The hearty delight enjoyed by the author himself in his intricate work finds an enthusiastic and almost poetical expression in the popular lecture by which the results were brought to the cognizance of a larger circle in the meeting of German Naturalists at Heidelberg in 1889, making Hertz's name one of the most popular of his country.

When in 1889 the University of Bonn was bereft of one of its most renowned celebrities by the death of R. Clausius, the famous pioneer in the mechanical theory of heat, the honors of the chair were offered to Hertz. He gladly accepted the call to the charming seat of science on the banks of the Rhine where his colleagues and the students were equally proud to offer him the most hearty welcome. While his lectures on experimental physics were addressed to a large number of students of all branches of natural science and medicine, a special course on mathematical physics gathered around him a select circle of pupils especially devoted to the field of physical research. His particular attention was directed towards increasing the facilities of the physical laboratory of the University so as to make it the centre of the efforts of those who under his guidance wished to enter the field of experimental investigation. In a colloginum he united with the more advanced of his students to discuss the leading problems and tried to introduce them into a full understanding of the productions of contemporary science.

The fame of Hertz's wonderful scientific success soon made his house the Mecca for a large number of visitors from all parts of the earth. The prominent feature that must strike everybody who made his acquaintance was the excessive modesty which gave a peculiar charm to his personal character. While ready to acknowledge emphatically every merit, however slight, in others, he never longed for praise for his own superior achievements. Free from any vain ambition he was exclusively governed by a pure and ardent desire for scientific progress.

In general conversation he showed a most diversified and universal interest. The earnest foundation of his scientific mind was accompanied by a sympathetic taste for the serene side of the human life, while the humorous touch which he liked to impart to his own narratives made it a fascinating pleasure to listen to him. To those who had once won his friendship he was dearly and permanently attached. His hospitable home—adorned by the charming wife (whose heart he had won during his stay in Karlsruhe) and by his two lovely children—was a picture of perfect happiness and offered the most cheerful abode to every guest who entered it.

A deplorable fate has severed the lovely bands which connected this unusual character to the highest scientific aims of the age, to his numberless friends and admirers, to the happiness of his cheerful home. Deep is the grief over this premature loss in every quarter of the scientific world. Endowed as very few are with the most acute perception of the secret ways of nature, combining the highest power of mathematical intuition with mastership in experimental investigation he seemed destined to lift the veil from many a mystery yet, and his friends confidently looked forward for further accomplishments of equal brilliancy to those by which he had filled the minds of his contemporaries with admiration. Seldom indeed has an early death dissipated brighter hopes than the passing away of our lamented friend, of whose life-work the very rays of light, the nature of which he so keenly disclosed, will speak to future generations. Bright as the laurels which he has joined to the wreath of honor of his nation will be the memory of his name in the hearts of all to whom science is dear; and brighter still will it be with those who were by personal friendship attached to his noble heart.

F. S. B.

ELECTRICAL UTILIZATION OF REFUSE AT HARROWGATE.

The City Council of Harrowgate, England, has resolved, it is stated, that an apparatus for the sorting and combustion of town's refuse be made a part of the electric lighting plant. Many "destructors" have been erected primarily with the object of burning the refuse, and the question of utilizing the heat evolved during such burning has either been entirely neglected, or at the best but a feeble attempt has been made to turn such heat to some useful purpose. On the basis of the results obtained in experimental tests there is enough fuel in the town ashpit refuse to supply steam power for an electric lighting plant double the size of the first equipment, and this without further capital outlay in a drying and sorting plant.

LITERATURE.

The Inventions, Researches and Writings of Nikola Tesla: With special reference to his work in Polyphase Currents and High Potential Lighting. By Thomas Commerford Martin. THE ELECTRICAL ENGINEER, *New York*, 1894. Illus. 496 pp., 6 x 9 inches. Price, $4.

THERE has been no one in the scientific field, unless it be the late lamented Heinrich Hertz, who during the past few years has attracted so wide attention among laymen and physicists alike as the subject of this sketch, nor has there probably been any one more generally misunderstood among all except those who have been specialists in somewhat the same lines as he.

Nikola Tesla, although for many years well known among electricians, has not until a comparatively recent date been known even by name to the layman, for he has appeared in public but a few times. The public lectures which he has delivered have attracted world wide attention however and have been faithfully reported by the electrical journals both in this country and abroad, but the intervals between their utterance have been such as to require closer attention even among professional men to connect them together than most of them have been able to give, and the newspaper reports were often so incorrect and even absurd, that the general opinion of what he had done has almost invariably been erroneous. Then too, all of his lectures have not been consecutive in thought nor intended to be, and it required a biographer thoroughly in the confidence of the great inventor and familiar with his work to fill in the gaps. And again, as I have said, by reason of the long intervals between his lectures, it became the more difficult to refer to the previous one in preparation for the new one. It involved the looking over of files of periodicals and these files were often wanting or inaccessible.

The purely popular interest with which Mr. Tesla's name and work have been surrounded may be imperfectly described by the standard of the throngs that were attracted to his lecture in St. Louis last spring. The largest hall in the city—the great auditorium at Exposition Hall—had been chosen for the occasion, yet this was jammed to the doors and thousands were turned away; while the scientific interest which they had aroused was equally well attested by the limited audience composed of the leading savants of all countries to which he spoke during the International Electrical Congress at the World's Fair.

The biographer in this case, Mr. Martin, was eminently fitted as everyone knows, to handle his subject in a literary way most satisfactorily, but it may not be so generally known that he was also eminently qualified for the task by reason of his long continued relations with, and friendship for, the man of whom he writes. With these two essential qualifications it would be strange if his attempt were not a successful one, and those who for these reasons expected an admirable fulfillment of the promise have had no cause for regrets at the result.

The book opens with an excellent full page portrait of Mr. Tesla. Then after a short preface and a table of contents comes Part I divided into 24 short chapters—the first one of which is chiefly biographical and introductory in character. The remaining chapters are devoted entirely to the polyphase current and its applications, describing his discovery of the now much used principle of the rotary magnetic field and the various applications which the inventor made of it. Each step is fully described and illustrated by cuts wherever the latter could be of service. Very much of this is either entirely new or, if previously published, so scattered as to render its collection by the average reader almost impossible. The experiments here described were all performed with alternating currents of the ordinary voltage and frequencies.

In Part II the author takes up Tesla's work with extremely high potentials and high frequencies. This will prove to many the most interesting part of the book as it may be said to be fundamental as respects that portion of his work which has aroused the most enthusiasm. It was the first public announcement of his work it this line that constituted Mr. Tesla's remarkable lecture before the American Institute of Electrical Engineers at Columbia College on May 20, 1891, and it was this same announcement that made him the cynosure of the eyes of the scientific world. The lecture itself is given in full in Chapter xxvi which is one of the eight comprising Part II.

It may be said at this point that it was only through the most untiring efforts and most urgent solicitations of Mr. Martin himself that this lecture was given at all, or rather, perhaps, that it was given at that time.

The enthusiasm aroused by this lecture abroad led Mr. Tesla to accept an invitation to England early in 1892, where he appeared before the Institution of Electrical Engineers, and a day later before the Royal Institution. The former of the two lectures takes up 97 pages and constitutes Chapter xxvii.

On Mr. Tesla's way to St. Louis to deliver his lecture there he stopped over at Philadelphia and addressed the members of the Franklin Institute—afterwards delivering with somewhat more elaboration the same lecture two or three days later before the National Electric Light Association meeting in Convention at St. Louis. This lecture, fully illustrated, constitutes Chap. xxviii.

The other four chapters of Part II are devoted respectively to Alternating Current Generators for High Frequency, Electrostatic Induction Apparatus, "Massage" with currents of High Frequency, and Electric Discharge in Vacuum Tubes.

Part III consisting of nine chapters, is devoted to what the author terms "Miscellaneous Inventions and Writings." This part is chiefly valuable as showing the great diversity of lines of research which Mr. Tesla has pursued. While it adds little to the book and practically nothing to the art, the volume would have been incomplete without it. A record of one's failures is sometimes quite as valuable to the world as a record of his successes. It certainly forms an appropriate chapter in the history of his achievements.

Part IV brings the history down to the time of the World's Fair. The first chapter of Part IV deals with Mr. Tesla's personal exhibit at the World's Fair. This is most admirably described and explained, and it is a pity that we did not have this chapter at least to inform us of the meaning and history of the many odd looking things while they were still assembled in Electricity Building. They were mostly historical machines each of which exemplified some important step in the evolution of now well known types; but the descriptions are accompanied by so many well executed cuts that many of us who saw them there will recall them, and if we did not then understand them, can now read the descriptions understandingly.

The second chapter—Chapter xliii—the last in the book, gives a running report of Mr. Tesla's lecture before the savants, already referred to. As this lecture was delivered to a limited few invited guests it was not taken down stenographically, but Mr. Martin has given a very fair abstract of it. The subject announced was "Mechanical and Electrical Oscillators," and those who were invited expected to hear the lecturer talk on some subject which his previous lectures had naturally led up to. What was their surprise however, to hear him talk about his achievments in an entirely different direction, namely mechanical reciprocating engines of an entirely new type, from which he hoped to obtain more easily, more economically and more surely, electrical results which he had already obtained by other means.

In conclusion it must be said, that Mr. Martin has been very happy in his language and exceedingly clear in his interpretations of hitherto misunderstood passages. He has done a real service to science in thus making accesible to all who desire it a complete and clear record of the sayings and doings of one who already has attracted so much attention and who, if not cut off like Hertz, to whom we naturally compare him, will do much more to entitle him to the niche in the temple of Fame which he has already earned. And it must be said further that the book is suitable not alone to those of technical acquirements but will be interesting to, and readable by, that now vast army of intelligent people who make science in its popular form a pastime.

NELSON W. PERRY, E. M.

LETTERS TO THE EDITOR.

MR. VAN NUIS ON THE PENNOCK "VOLT DISTRIBUTOR."

My attention has been called to a circular, issued by George B. Pennock, in which my name is unwarrantably used, and which, to say the least, is misleading.

To a casual observer, this circular would appear to be a report of an exhaustive test of the Pennock system of multiplying power by a "volt distributor," and assumes that I would be responsible for the statements and figures contained therein.

A more careful perusal of the subject, however, would reveal to the experienced engineer the real object of the author (to mislead) so there is little need of warning for those posted in such matters; but, for the benefit of laymen, and would-be investors in electrical enterprises, allow me to say, through the columns of your paper, that I have never made a detailed report of the Pennock system of distribution for anyone.

At the solicitation of a client, I called at Mr. Pennock's laboratory, to investigate the workings of the machine. After listening to Mr. Pennock's explanation of, and claims for, his crude apparatus, and taking several readings of the current output of his battery while doing various kinds of work, I was unable to report a multiplication, or saving, of power to any extent whatever, by the use of the "volt distributor," much less to verify Mr. Pennock's large claims to economy.

Before seeing Mr. Pennock's apparatus, I suggested to my client that the electricians of the country condemned it as a fraud, though I visited the exhibit in Boston with a fixed determination to give due credit to any point of merit I might be able to discover.

My search for merit was fruitless, but a careful survey of the exhibit, and of the methods employed by Mr. Pennock and his satellites, confirmed the report I had heard of this system in other localities.

A hungrier set of parasites is seldom seen, seeking as their prey any one with money. The bunco steerer's vocation seems mild when compared with this.

In the circular referred to, Mr. Pennock has arbitrarily assumed conditions and figures to suit his own conveniences, while the facts in the case do not warrant a single conclusion in this truly wonderful document.

C. S. VAN NUIS.

NEW YORK, Feb. 2, 1894.

NON-INFRINGING TELEPHONE TRANSMITTERS.

IN the columns of one of your esteemed contemporaries, a contributor undertakes, as he says, to point out to inventors the lines upon which they may work with a reasonable expectation of producing a practical non-infringing telephone transmitter. He refers, among other devices, to a pair of electrodes separated from each other and immersed in water, and to a pivoted lever attached to the diaphragm, which varies the resistance by moving a contact over the terminals of a rheostat. In the innocence of his heart, he cites these archaic and preposterous contrivances as proof "that it is possible to construct a *practical* transmitter without infringing the Berliner and Edison patents!" If this gifted scientist should ever, by any unlucky chance, find himself immured in a dungeon cell, under sentence to be deprived of food and drink until such time as he succeeded in making his wants known to the outer world through the instrumentality of a telephone transmitter of either of the above-named "practical" types, it is much to be feared that his fate would be no less tragic than that of the ill-fated prisoner who was condemned to be immured alive in a wall of solid masonry. It would seem as if the most elementary knowledge of the necessary conditions of telephonic transmission would have been sufficient to have prevented the publication of such worthless and misleading "expert" advice as is contained in the communication referred to.

BOSTON, Jan. 27, 1894.

ARC LAMP DESIGN.

In the London *Electrician* of Dec. 8 there appears a reprint of an article on the above subject by the writer, taken from THE ELECTRICAL ENGINEER of Nov. 15, which is commented upon editorially in that journal as follows:

> SOME of the difficulties in the design of arc lamps which are enumerated by Mr. W. A. TURBAYNE, in his article which we publish this week, are undoubtedly of importance; the others are rather trite. It is the fashion to say that the mechanism of arc lamps has been neglected, but, while this would have been true a year ago, it is not by any means true now, at any rate, as regards English lamps. During the last twelve months considerable attention has been given to arc lamps, both by makers, in regard to their mechanism, and by physicists, in regard to their distribution of light and the relation between watts, volts and carbons. However, it is quite true, as Mr. TURBAYNE points out, that there are still some important difficulties in the way of making a perfect lamp. But it is by no means clear how any of these difficulties are to be got over, in the case of running lamps in series, by a return to the old-fashioned series-coil method of feeding the carbons. To us, Mr. TURBAYNE's assertion that "the best foundation design for an arc lamp for direct-current working would undoubtedly be that of the *non*-differential variety," is simply unintelligible. The essential property of lamps run in series is that they shall regulate without influencing one another, and without any change of current. How can any such independence be obtained where there is a series feed?

Will you allow me space to set the writer of the above right as he has evidently misunderstood the general meaning of the term "non-differential" arc lamp.

In this country a non-differential lamp is generally supposed to be one in which the arc is controlled only by the shunt magnets; in other words, it is purely a shunt feed lamp and a lamp which certainly regulates when run in series, irrespective of the number in circuit, providing the E. M. F. is sufficient, as with any lamp, and the design is proper. It is needless to say that some of our most prominent systems of arc lighting now comprise a non-differential lamp and many of the constant potential lamps are also of this form.

I do not understand how the writer of the above criticism considered me to refer to a series feed, as my article plainly refers to a shunt feed lamp all along and positively states that "the main current has nothing whatever to do with the regulation;" this could hardly be called a series feed. We know that a lamp can regulate simply by the variations of main current, and such lamps are being made every day, especially single burning alternating lamps; but one would hardly have the nerve to propose such a thing for series lighting.

My article in THE ELECTRICAL ENGINEER, simply stated that the non-differential possessed numerous advantages over the differential form of lamp especially if the arc did not tend to elongate, during continued burning, by the heating of shunts or gradual decrease in weight of carbon, and thus call for a greater E. M. F. than the dynamo was capable of producing, resulting probably in serious "pumping," etc.

No one is more appreciative than myself of British arc lamps, especially of their substantial and weatherproof qualities.

WM. A. TURBAYNE.

DETROIT, MICH.

OBITUARY.

MRS. G. M. PHELPS.

It is with deepest pain and regret that we record the death, on Feb. 10, in Brooklyn, at the age of 47, after a brief illness, of Mrs. Annie Lapham, wife of Mr. George M. Phelps, president of THE ELECTRICAL ENGINEER. Funeral services were held on Feb. 11, and the body was carried next day to Troy for cremation and interment in the family plot in the cemetery there. Through her husband, Mrs. Phelps was known to a large circle of electrical friends and acquaintances, here and in Europe. Of her benevolence, charity, and sunny, serene disposition, a tender memory remains to her household and those among whom she went about quietly doing good. A painful death was faced with noble courage and sweetness. From the ENGINEER staff, as from all others who know them go forth profound feelings of sympathy with her daughter, and with the husband thus bereaved on the morrow of the twenty-fifth anniversary of his wedding day.

LEGAL NOTES.

LAMP SOCKET LITIGATION.

ON Jan. 25 argument was heard before Judge Coxe in the U. S. Circuit Court at Albany in the suit of the Edison Electric Light Co. (General Electric Co.) vs. The Electrical Engineering & Supply Co., of Syracuse, in the suits for infringment of patents covering lamp sockets. The patents sued on are those of T. A. Edison, No. 265,111, which is claimed to be the "foundation" socket patent; the metal covering patent of E. H. Johnson, No. 251,596; and three patents of S. Bergmann, Nos. 257,277, 293,552 and 298,658, covering various details. Messrs. R. N. Dyer and C. E. Mitchell appeared for the complainants and Messrs. Hay & Wilkinson for defendants. A decision is looked for within a few weeks.

MORE STORAGE BATTERY LITIGATION.—BRUSH vs. CHLORIDE.

THE BRUSH ELECTRIC COMPANY and the Consolidated Electric Storage Company as complainants have brought suit against the Electric Storage Battery Company (manufacturers of the "Chloride" accumulator), for infringement. Motion for preliminary injunction will come on to be heard before Judge Green in the United States Circuit Court at Trenton, on February 20. The suit is brought on the Brush storage battery patents, notably U. S. patent No. 337,299 for the broad claims covering the mechanical application of active matter, or matter adapted to become active, to a frame or support.

SWITCH PATENT LITIGATION.

THE suit of the Schuyler Electric Co. vs. the Electrical Engineering and Supply Co., of Syracuse, came up before Judge Coxe at Albany at the last term in January. This suit was brought for alleged infringment of the Perkins switch patent in the lamp socket, embodying a rotating ratchet and fixed pawl. Mr. C. L. Buckingham, appeared for complainants, and Messrs. Hay & Wilkinson for defendants,

EDISON ELEC. LT. CO. vs. DAVIS ELEC. CO.—APPEAL—LAMPS MUST NOT BE REPAIRED.

A decision on the appeal of the Davis Company against the decision of Judge Colt, in favor of the Edison Elec. Lt. Company, enjoining them from repairing Edison incandescent lamps, has been rendered by the Appellate Court in favor of the Edison Company.

SOCIETY AND CLUB NOTES.

THE N. E. L. A. CONVENTION AT WASHINGTON—SPECIAL TRAIN.

MR. C. O. BAKER, JR., Master of Transportation, has issued the following notice from headquarters. We may add that the attendance promises to be very large. It is said that some fifty ladies have already been registered to form part of the gathering.

> The various Passenger Associations have granted a rate of fare and one-third for the round trip from all points east of Chicago, Burlington and Peoria and the Mississippi River to Washington, D. C. Negotiations are now pending with the Western Traffic Association for members in that territory to secure this rate. Ask the ticket agents from whom you purchase your ticket for Delegate Certificate to National Electric Light Association Meeting, which, when properly filled in and certified at Association headquarters in Washington, will entitle you to return for one-third the regular fare.
>
> A special vestibuled train, composed of Parlor, Cars, will leave via Royal

Blue Line, Foot of Liberty Sireet, New York, at 1:30 p. m., Monday 26th inst.; and will leave Twenty-fourth and Chestnut Streets, Philadelphia, at 3:20 p. m., arriving at Washington, D. C., 6:20 p. m. Seat checks for this train can be procured from the undersigned at $1.25 each, and railroad tickets from New York to Washington at $6.50 each. Railroad tickets can also be obtained at any Blue Line Ticket Office. Be sure to get a certificate when purchasing ticket. Please make checks payable to C. O. Baker, Jr.

NEW YORK ELECTRICAL SOCIETY.—CANAL PROPULSION.

The next meeting of the Society will be held at Columbia College, 49th street and Madison ave, on Thursday, February 15, at 8 p. m. Mr. Joseph Sachs will deliver a lecture on: "Electric Canal Boat Propulsion, with special reference to the Erie Canal." *Synopsis:* 1. The Erie Canal agitation; 2. The necessary requirements for a feasible system; 3. Several ways in which boats can be electrically operated on the Erie Canal: (*a*) propeller, (*b*) cable hauling, Belgian system, (*c*) rack or rail hauling with stationary rail on bank or overhead, motor on boat gripping rail by means of an arm from the boat, (*d*) movable cable on bank and gripping devices on an arm extending from the boat, (*e*) motor on bank, i. e., locomotive on bank or overhead; 4. Comparison of the various methods and their efficiency, including the cost of installation and operation of propeller and hauling method; 5. General considerations of canals other than the Erie. The lecture will be fully illustrated by means of the lantern.

THE UNIVERSITY EXTENSION LECTURES.

The lecture by Mr. A. E. Kennelly, on Electrical Measurements, at Cooper Union, on Feb. 5, was well attended and was very interesting. The exposition of the subject, with the free aid of illustration, was in Mr. Kennelly's best vein, being clear, simple and thorough.

The lecture by Prof. F. B. Crocker on Electric Lighting, to have been delivered on Feb. 12, has been postponed until this evening (Feb. 14) as Monday was Founder's Day at the Cooper Union.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED JANUARY 30, 1894.

Alarms and Signals :—

Train Operated Device, J. H. Frischen and R. Pfeil, Berlin, Germany, 513,498. Filed Nov. 28, 1893.

A signaling device for steam railways arranged so as to have different effect upon the semaphores according to the direction in which the train is moving.

Fire Alarm Telegraph System, M. J. O'Sullivan, Baltimore, Md, 513,526. Filed June 7, 1893.

Electromechanial Device for Bells, &c., W. O. Meissner, Chicago, Ill., 513,587. Filed Sept, 11, 1893.

Annunciator, J. H. McEvoy, Waterbury, Conn., 513,592. Filed May 8, 1893.

Electric Bell, J. H. McEvoy, Waterbury, Conn., 513,593. Filed May 8, 1893,

Electrical Registering Device, F. Von Hefner-Alteneck, Berlin, Germany, 513,612. Filed Nov. 3, 1893.

The invention relates to apparatus for recording railway signals upon a strip of moving paper.

Annunciator, M. Garl, Akron, Ohio, 578,775. Filed June 28, 1893.

Automatic Circuit Closer, H. Lawers, Carson City, Nevada, 513,796. Filed July 11, 1893.

A thermostatic circuit closer especially adapted for automatic fire alarm.

Electric Alarm, D. S. Schureman, Rockford, Ill., 513,829. Filed May 6, 1893.

A dial thermometer with conductors so arranged as to make contact with the pointer and ring an alarm at a predetermined temperature.

Annunciator, F. W. Ross, Boston, Mass., 513,956. Filed Oct. 6, 1893.

Conductors, Conduits and Insulators :—

Anti-inductive Conductor, H. F. Chick, Waterton, Mass., 513,482. Filed May 29, 1893.

Employs a separator of textile material wound about and between the two conductars and permanently attached to one of them.

Electric Wire Cleat or Holder, A. W. Fuller, Saugus, Mass., 513,564. Filed Mch. 13, 2893.

Consists of a many-sided block having two parallel grooves formed upon two or more of its sides.

Detachable Electric Wire Holding Device, C. Beard, Brookline, Mass., 513,630. Filed Oct. 20, 1893.

A detachable clip embracing the support and provided with an eye through which the wire passes.

Connector For Electric Wires, E. H. Munson, New Britain, Conn., 513,949. Filed May 9, 1892.

A water tight coupling easily made and broken and especially adapted to testing apparatus.

Distribution :—

System of Electrical Distribution, C. H. Talmage, St. Louis, Mo., 513,839. Filed Mch. 31. 1893.

Relates to means for automatically regulating the quantity of electricity supplied to electrical translating devices.

System of Electrical Distribution, W. Stanley, Jr., and J. F. Kelly, Pittsfield, Mass. Reissued, 11,400. Filed Nov. 29, 1893.

Has for its object to provide a self regulating transformer system in which the primaries of the induction devices are connected in series with the main, or inducing, circuit and the translating devices in multiple with the secondaries by which they are supplied with current.

Dynamos and Motors :—

Commutator, G. A. Rollins, Chicago, Ill., 513,533. Filed Apl. 11, 1893.

Employs commutator bars secured and insulated at their ends and separated along their middle portions by air spaces.

Dynamo Brush, W. H. Fleming, Bayonne, N. J., 513,611. Filed Nov. 13, 1893.

Claim 1 follows:

A dynamo brush consisting of successive layers of wire gauze formed into the desired shape and then compacted by pressure. (See THE ELECTRICAL ENGINEER Feb. 7.)

Lamps and Appurtenances :—

Electric Arc Lamp, F. A. Perret, Brooklyn, N. Y., 513,725. Filed Nov. 7, 1892.

The invention consists of a train of wheels geared to the upper carbon rod, a rotary armature controlling the movement of said train, a pivoted frame supporting said train, and an electromagnet connected with the frame and controlling the rotary armature.

Electric Arc Lamp, M. R Gutierrez and M. T. Thompson, Jalapa, Mexico, 513,921. Filed Aug. 8, 1893.

Employs two carbons both supported at their right upper ends, the lower ends coming together in the shape of a V, and feeding mechanism for maintaining the lower ends at a proper distance apart as the carbons are consumed.

Incandescent Lamp Socket, J. McFarlane and W. B. Edgar, Glasgow, Scotland, 513,931. Filed Mch. 31, 1893.

The invention relates especially to a switch of cheap construction contained within the socket.

Metal Working :—

Electric Furnace, E. Thomson, Lynn, Mass., 513,602. Filed June 10, 1886.

Employs a heat producing conductor packed in a non-conductor of heat consisting of blocks of carbon pressed together.

Miscellaneous :—

Mechanism for Controlling Engines, B. F. Teal, Chicago, Ill., 513,601. Filed Aug. 14, 1893.

An electrically operated valve by means of which the steam pressure in the supply pipe is made to actuate a small piston closing or opening the steam passage.

Electrolytic Cell, C. T. J. Vautin, London, Eng., 513,661. Filed Apr. 19, 1893.

Claim 1 follows:

A mercury electrode comprising a chamber or pocket with mercury therein, the metallic joint internally surrounding said chamber, and capable of amalgamation with mercury and the non-conducting reticulated mesh sieve or perforated plate extending over the opening of the said chamber to hold the mercury in place.

Automatic Damper-Regulator, H. F. Maxim, Norfolk, Va., 513,948. Filed Mch. 14, 1893.

Railways and Appliances :—

Trolley Wire Finder, E. Gale, Peoria, Ill., 513,566. Filed Nov. 21, 1892.

Claim 3 follows:

The combination of the trolley pote and wheel with a revoluble finder-spool near the wheel, extending laterially beyond the vertical planes of the sides of the wheel, and mounted on lever-arms pivoted or in line with the journals of said wheel.

Electric Connection for Railway Rails, A. Green, Rochester, N. Y., 513,777. Filed Sept. 30, 1893.

Provides means for the removal or substitution of a single rail without interrupting the current.

Trolley Pole Stand, G. Valley, Cleveland, O., 513,846. Filed, May 6, 1893.

Trolley Pole Stand, G. Valley, Cleveland, O., 513,847. Filed May 11, 1893.

Electrically Propelled Drive Wheel, C. G. Anderson, Lynn, Mass., 513,859, Filed Sept. 1, 1892.

Employs a stationary motor arranged within the wheel and secured to the shaft, and intermediate gearing between the motor and the edge of the wheel.

Sectional Electric Railway, G. W. Demmick, Lynn, Mass., 513,894. Filed July 20, 1893.

A system in which the wheels of the truck make contact with the different sections of the conductor which are automatically cut out of circuit after the car has passed.

Power Transmitting Mechanism for Electric Locomotives, M. W. Dewey, Syracuse, N. Y., 513,895. Filed Apl. 17, 1891.

Employs an electric speed reducing mechanism connected to the moving part of the motor and to the shaft and consisting of two parts adapted to electrically attract or repel each other and a friction clutch connected to the moving part of the motor and also to the shaft.

Insulated Rail Chair, L. McCarthy, Boston, Mass., 513,950. Filed Sept. 27, 1892.

Switches and Cut-Outs :—

Circuit Controller for Regulators, B. B. Ward, New York, 513,545, Filed May 10, 1893.

An automatic circuit controller designed to have a certain amount of lost motion and then to make or break the circuit with an instantaneous snap.

Automatic Rheostat, C. J. Sturgeon, Erie, Pa., 513,626. Filed Mch. 31, 1893.

Switch Bar, F. A. Weller, Boston, Mass., 513,745. Filed Feb. 27, 1893.

A switch for shunt wound motors with which both the field and armature circuits may be instantly broken and again established through the greatest rheostat resistance when it is desired to start the motor.

Telephones and Apparatus :—

Signaling System for Telephone Circuits, J. I. Sabin and W. Hampton, San Francisco, Cal., 513,534. Filed Aug. 18, 1893.

Provides apparatus by which the subscriber operates a visual signal at the switching station automatically by the act of removing the telephone from its hook.

Signaling System for Telephone Trunk Lines, C. E. Scribner, Chicago, Ill., 513,537. Filed June 16, 1893.

Provides means whereby an operator in a telephone exchange is automatically notified of the connections established by other operators in the same exchange.

Telephone, H. S. Page, Somerville, Mass., 513,720. Filed May 15, 1893.

Employs a diaphragm of insulating material the outer surface of which is carbonized and the inner surface platinized, two electrodes in contact suspended by a conducting support, one being in contact with the platinized surface, and the whole included in the battery circuit.

Telephone Transmitter, F. H. Richards, Hartford, Conn, 513,729. Filed Dec. 4, 1893.

Employs a compound electrode supported upon the frame of the transmitter and a follower electrode connected with the diaphragm and supported against the working face of the compound electrode.

Telephone Transmitter, F. H. Richards, Hartford, Conn., 513,730. Filed July 31, 1893.

Similar to No. 513,729.

Automatic Telephone Switch, A. C. Wheat, Chicago, Ill., 513,960. Filed June 5, 1893.

Employs a shifting contact maker carried by the receiver hook and operating by gravity.

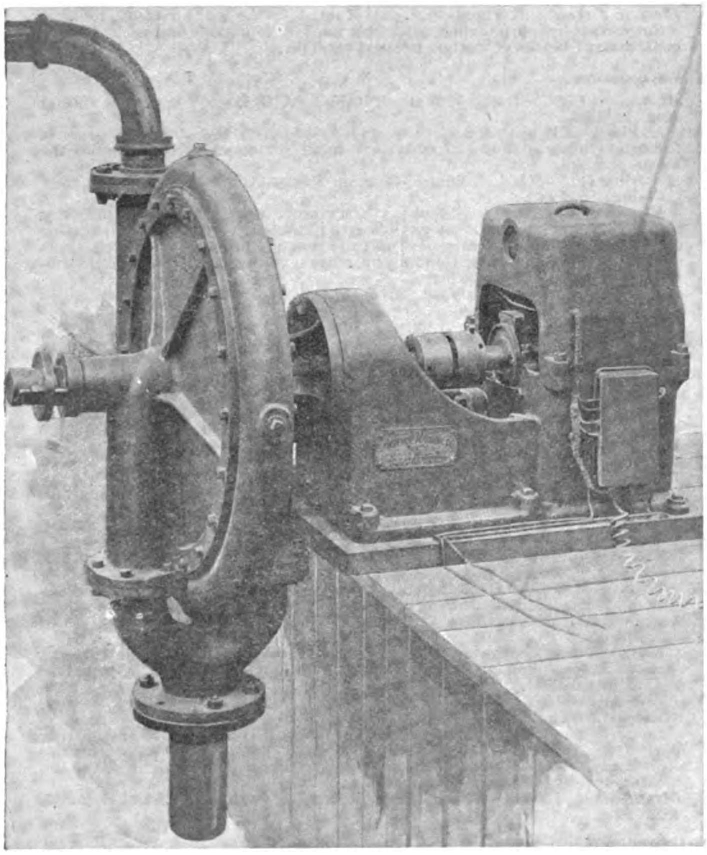
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

ELECTRIC CENTRIFUGAL PUMP.

AMONG the many types of electric pumps exhibited by the General Electric Company in its Power and Mining Section at the Chicago Exposition, the electric centrifugal pump, ejecting its broad stream of water into the reservoir in Electricity Building attracted considerable attention.

The pump itself, illustrated in the accompanying engraving, is a No. 4, four inch, centrifugal pump, manufactured by the Lawrence Company. The shaft of the pump is direct connected to the shaft of the armature of a General Electric iron clad No. 2½ W. P. motor, running at 400 revolutions at which speed it develops 8 H. P. This pump is intended for use where muddy or dirty water is encountered, which would quickly destroy the usefulness of any valves of the ordinary pump. It has proved remarkably efficient wherever it has been used, especially in raising water for irrigation purposes.



G. E. ELECTRIC CENTRIFUGAL PUMP.

J. G. WHITE & CO.

THE contract for erecting the electrical equipment of the Edmondson Avenue and Monument Street Lines of the Baltimore Traction Company has been let to J. G. White & Co. of this city, the contractors who have built all the other electric lines of the company. The Edmondson avenue line will be double-tracked to North avenue. At present there is only one track beyond the B. & P. R.R. bridge on Edmundson avenue. The Monument street line will follow the present tracks. If the weather permits, the contractors will commence setting poles at once. It is said the bidding was very close, and that superior construction work was the cause of the contract being awarded as it was. Mr. C. G. Young is the electrical engineer in charge of the work for J. G. White & Co.

THE ROBBINS PASTE BATTERY.

MR. A. C. ROBBINS, of Watsonville, Cal., has recently introduced a new dry battery for telephones, bells, annunciators, medical and spark coils, and all open circuit work. The Robbins paste battery is claimed to be as effective and as economical as the Leclanche, without the objectionable features of the latter.

It is also said to be non-poisonous and to contain neither acid, alkali, nor ammonia. The number 1 size, 3 inches high and 2½ inches in diameter, will, it is claimed, operate an ordinary call-bell and push-button circuit satisfactorily for from six months to one year, without any attention whatever. When exhausted, this battery can be recharged by a current of from two to five volts from an ordinary gravity battery. The battery is made in six sizes.

SWEDISH CHARCOAL IRON FOR ARMATURES AND TRANSFORMERS.

THERE is probably no one thing which has contributed more to progress in the construction of dynamos and transformers than the recognition of the fact that heating and other losses are due largely to the inherent quality of the iron employed. What may be very good soft iron for some purposes may be totally unfit for work of this kind and it has required much time and experience to manufacture the quality of iron best suited to this purpose. Among those who have devoted special attention to the manufacture of iron for armatures and converters are Messrs. Jos. Sankey & Sons, of Bilston, England, who are represented in this country by Mr. Geo. L. Colgate, of 136 Liberty street, New York. Transformer work is specially trying to the iron and the perfection to which the above mentioned firm have brought their Swedish charcoal iron is seen from the fact that transformer stampings show only an average loss of $\frac{6}{10}$ of a watt per pound, at a frequency of 100, with an induction of 4000 C. G. S. units; this is claimed to be more than equal to the mild steel used by some manufacturers in this country and the cost of the iron is considerably less than the steel. The use of this iron in armature cores reduces the heating effect and materially increases the efficiency of the machine.

One great advantage to the manufacturer is that Messrs. Sankey & Sons make no charge for tools that may have to be made on account of deviations from the sizes and styles of stampings they have already made, and for which they have tools in stock. Aside from the great advantage of the quality in their iron there are also other advantages to the manufacturer, notably the following: The stampings come to him ready for use; he needs no large investment in presses and other special tools; he needs no department in his factory to accommodate these tools and the necessary workmen; and he saves the waste and the repairs and the cost of labor and he gets a uniform iron.

There is another point which has been found to be of great importance, and which is quite necessary where the iron is used in transformer work, and that is, that stampings that have been bent and straightened again do not give the same results as when the iron is carefully kept flat, and it is believed the iron loss in the company's transformer stampings is considerably less owing to careful handling, than when the stampings are made by inexperienced people.

Another point of importance is that in the process of annealing the iron is given a finish which does away with the necessity of placing insulating material between the plates.

Since Mr. Colgate has begun to introduce this iron into America, he has secured orders from many of the leading companies, and in every instance it has given entire satisfaction and secured permanent customers.

"N. I. R." WIRE IN CHICAGO.

THE METROPOLITAN ELECTRIC COMPANY, General Western Agents for "N. I. R." wire and cables, have just recently had some very satisfactory tests from two of the largest buildings in Chicago, in which their wire is used.

The "N. I. R." factory have enlarged their line of products, and are now making electrolier wire, lamp cord, rubber and friction tape; all in harmony with their regular wires and cables.

A full stock of these goods will be carried by the Metropolitan Electric Company, at prices to suit the times.

PURITY OIL FILTER CO.

THE list of recent sales of the Purity Oil Filter includes names of companies from California to New York and from Wisconsin to West Virginia, besides which many applications for machines on trial have been received. An improvement of considerable merit in these filters has lately been made, the particulars of which may be learned by addressing the company in Pittsburgh.

THE ELECTRIC APPLIANCE COMPANY have recently added several improvements to their now celebrated Washington alternating arc lamp which make the lamp even more desirable than it was as originally placed on the market. A highly polished metal reflector has been placed over the outside of the globe which can be used or not as desired. The metal base of the lamp has been done away with entirely leaving nothing whatever on the lower part of the globe to obstruct the light and also shortening the lamp several inches, so that a 15 hour lamp is only a trifle over 20 inches long over all.

OHIO BRASS COMPANY RAILWAY SPECIALTIES.

The accompanying illustrations show some new devices for electric railway work, just being introduced by the Ohio Brass Company of Mansfield, Ohio. Figs. 1 and 2 represent Wood's adjustable two and three way switch. The tongues of this switch being pivoted in the body admit of a wide range of adjustment, and it can be used equally well for a right hand, left hand or Y turn out. The two way style will answer for all turn outs, which makes it very convenient for new work. The three way switch is substantially the same as the two way except that the pan is made broader to admit of the use of three tongues. In fastening the short end of the trolley wire in the switch no soldering apparatus is required. The wire is laid in the tongue and the clamping pieces at the ends are hammered down over it and held in place securely by means of the screw cap and clamping piece which is attached to a lug on the tongue of the switch. This also acts to fasten the tongue at the desired angle.

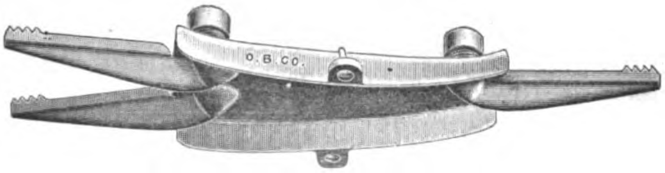


FIG. 1.—WOOD'S TWO-WAY SWITCH.

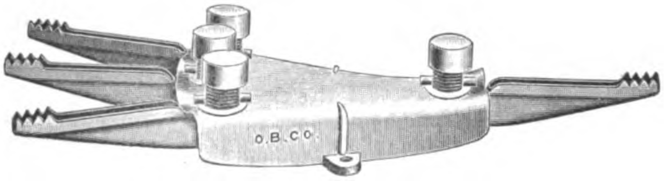

FIG. 2.—WOOD'S THREE-WAY SWITCH.

The threaded trolley splicer is shown in Fig. 3. To make a splice the ends of the trolley wire are threaded with a small die furnished for the purpose, and the thimbles are then screwed on and fit into the recesses in the coupler. The two parts of the coupler are then screwed into each other making a strong compact splice but a trifle larger in diameter then the wire itself.

FIG. 3.—THREADED TROLLEY SPLICER.

The feeder wire splicer, Fig. 4, can be used as a permanent or temporary connector. The halves of the splicer are placed over the abutting ends of the bare wire, and the nut is then screwed on the tapered ends. These are slightly corrugated on the inside to securely clamp the wire. If a permanent splice is desired solder can be poured through a slot provided for this purpose. A joint made in this way is but a trifle larger than the wire and is of low resistance and great strength.

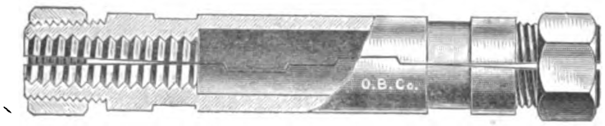

FIG. 4.—FEED WIRE SPLICER.

BERLIN IRON ROOFS.

The Berlin Iron Bridge Co., of East Berlin, Conn., have received the contract for an iron roof for the boiler and engine room of DeLand & Co., at Fairport, N. Y. The roof will be covered with The Berlin Iron Bridge Company's patent anti-condensation corrugated iron. The new mill of The Diamond Mills Paper Co., at Millbank, N. J., is being put in place by The Berlin Iron Bridge Co. The Citizens' Gas Co., of Brooklyn, N. Y., have placed the order for an iron roof for their new producer house, with the Berlin Iron Bridge Co. The building is 69 ft. wide and 151 ft long, with an iron roof covered with slate.

QUEEN "HOT WIRE" INSTRUMENTS.

QUEEN & Co., INC., of Philadelphia, are about to introduce a variety of standard voltmeters on the "hot-wire" plan made under the fundamental Cardew and other more recent patents. These instruments prove extremely accurate for both direct and alternating circuits, which is confirmed by an award received at the World's Fair for "Success attained in *overcoming* the defects of the ordinary hot-wire instrument, viz.: Lack of great range through which the instrument is sensitive, great correction due to change of temperature and inconstancy of zero point, and also for its compactness, portability and excellence of mechanical construction."

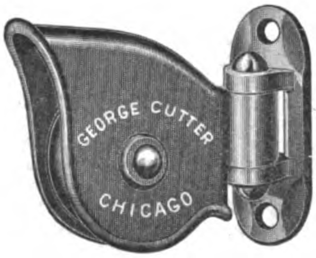
Exhaustive experimental work conducted in the Queen laboratory for more than a year past, enables the makers to feel great confidence in the efficiency of the "Acme" standard voltmeters, the portable type of which will be ready for sale in a few weeks. A price list and full particulars will be issued shortly.

SOUTHERN NEW ENGLAND TELEPHONE CO.

THE above company with headquarters at New Haven, Conn., has issued a very neat calendar for 1894, of which a copy has been sent us, accompanied by a list of towns and post offices in Connecticut and by a memorandum book that contains a list of pay stations for the use of non-subscribers. All the data is useful and well prepared.

CUTTER'S NEW POLE PULLEY.

The new year would not be doing itself justice if it did not bring some more of the "better things" devised by George Cutter. The first of these comes in the shape of a new swivel pole pulley, well shown by the cut. Most of our readers are acquainted with the older form of swivel pole pulley, which has been used extensively for several years, and which is said to be giving the best of satisfaction. The new type is built on the same general lines, but instead of requiring a special screw for fastening it to the pole, it has a wall-plate which can be secured with a couple of ordinary lag screws. This wall plate is made of malleable iron and curved so as to fit the pole, making the support both strong and quite rigid. That such a pulley will always swing into line with the hoisting rope so as to avoid any chafing of the rope, is evident, and this point, added to its other good features, will no doubt command a good market for it. It is made and handled by George Cutter of Chicago.



CUTTER'S NEW POLE PULLEY.

INFRINGEMENT OF THE STAR VENTILATOR.

IN the Omaha *Sunday World Herald*, of December 17th, appears a paragraph in regard to an alleged infringement of the patent of Merchant & Co.'s Star ventilator. It would seem that the Star ventilator was specified for the Lincoln, Neb., Hospital for the Insane and that the contractor placed other ventilators in the building, which Merchant & Co. claimed to be infringements on their Star patents. Steps were accordingly taken to stop payment on the work pending an investigation. The matter was duly laid before the State Board of Public Lands and Buildings, with the result that the board decided to withold a settlement with the contractor until he had made a satisfactory settlement with Merchant & Co. We are informed that Merchant & Co. have recovered heavy damages in the case.

REDUCED PRICES FOR "SECO" LAMPS.

THE SOUTHERN ENGINEERING CO., of Louisville, Ky., has issued an announcement of reduced prices for its "Seco" incandescent lamps, making the rate 32½ cents for lamps up to 20 c. p.; 38 cents for 25 c. p. and 45 cents for 32 c. p. Special prices will be quoted on special lots or special makes. Any lamp proving defective within ten days of normal use will be replaced free of charge.

RE-ORGANIZATION OF THE MATHER ELECTRIC COMPANY.

FOR several weeks a movement has been on foot for the transfer of the Mather Electric Company of Manchester, Conn., to a syndicate of Hartford capitalists. All the details of the transfer have now been arranged and new men will take charge of the company and its affairs. The old directors resigned Saturday, and at a meeting of the stockholders in the afternoon at the Phoenix National Bank, officers were chosen as follows: President, Maro S. Chapman; vice-president, T. C. Perkins; secretary and treasurer, John L. Bunce; directors, Charles E. Perkins, T. C. Perkins, M. S. Chapman, Henry A. Redfield, Charles M. Jarvis, John L. Bunce, Norman McD. Crawford.

Mr. Charles E. Perkins is a well-known lawyer in Hartford, and his son Mr. T. C. Perkins, who becomes vice-president, will assume all the active duties of the management. Mr. T. C. Perkins is well known in New England, and though still young in years, has had a varied experience in the electrical field, and knows well just what kinds of dynamos and motors are required. He is also well known in the West, having been associated with Mr. W. B. Pearson in the management of the Chicago office of the Ball & Wood Company. Mr. Perkins has the reputation of being enterprising and pushing in the extreme, and will lend all his youthful energies to the business. Mr. Henry A. Redfield is president of the Phœnix National Bank, Hartford. Mr. C. M. Jarvis is widely known as the general manager of the Berlin Iron Bridge Company, of East Berlin, Conn. Mr. Chapman is in charge of the Government Envelope Works in Hartford, and is also president of the Perkins Electric Lamp Company, and the Waring Electric Company. Mr. Crawford is a consulting electrical engineer of Philadelphia, and is at present electrician of the Hartford Street Railway Company. Mr. Bunce who will be directly associated with Mr. Perkins has had several years' experience in the electrical business, having been with the Schuyler Company and the Perkins Switch Company.

The new officers have engaged as superintendent of the electrical and manufacturing departments Theodore Gonet, an electrical engineer who is at present with George Westinghouse, of the Westinghouse Electric and Manufacturing Company of Pittsburgh. He will have associated with him W. E. Powell, who is now with the Mather Company. The company starts out under the re-organization free from debt and with a working capital of about $80,000 outside of the stock capitalization of the company. Electrical supplies of various kinds will be made, but the company will make a specialty of large dynamos and generators for electric lighting plants and electric street car systems.

Recently the Mather Company made an addition to their factory of a building 200 feet by 50 feet, with a traveling crane capable of lifting 20 tons, so that they are now well equipped to manufacture the largest sizes of generators and dynamos. The old ring type of machine will still be used, but new types will be developed in the heavy railway generators as soon as practicable. The shops are running light at present, but it is expected that a large force of men will be put to work in the near future, and before long it is hoped that 200 to 300 men will find employment with the Mather Company.

MUNICIPAL CONDUIT SYSTEMS IN MASSACHUSETTS.

A bill has been introduced into the Legislature of Massachusetts to enable cities and towns to construct, maintain and lease conduits and the connected structures for electrical wires, cables and conductors. The bill provides that

> Any city or town in which electrical wires, cables, etc., are in use over, along or across any public way, may accept the provisions of the act, and thereupon proceed to construct, operate and maintain conduits, manholes and the necessary distributing boxes and service pipes connected therewith and may compel any and all corporations, firms and individuals using the wires, etc., to place the same in such conduits and man-holes and compel owners of wires within ninety days after the service of notice to remove the same from over or across public ways; if the wires are not removed within ninety days, the city or town may remove them at the cost of the owner; a city or town may defray the cost of such conduit by issues of bonds to be called "Conduit Loan Bonds," to run not over thirty years and bear interest at a rate of not more than five per cent.; a rental not exceeding $500 per mile annually for each three-inch duct in the conduit may be charged for use of the conduit.

Nothing in the act is to be construed as referring to trolley wires of street railway companies or supporting wires for the same. In case there is an existing conduit in a city or town it may be taken upon terms agreed upon by the parties, or at a price, in case of disagreement, fixed by a method provided for by the bill. No public highway is to be interferred with without the consent of the public highway commission.

UNDERGROUND WIRES IN ST. LOUIS.

PRESIDENT McMATH of the St. Louis Board of Public Improvement says that in case a conduit system is required by the city a grand trunk subway would probably be built to lie north and south. It would be built very like a sewer, the material used in its construction being either brick or concrete. The interior would be large enough for workmen to move in, and the cables carrying the wires would be laid on shelves or brackets on the sides.

In this subway would be laid all kinds of wires, including the supply wires of the street railroad and electric light companies. At right angles from this grand trunk subway and at intervals of not less than two blocks submains would be required, consisting of 20 or less ducts, carrying the cables of all companies. These conduits could be laid under the sidewalk and when put down be subject to calculations ahead for 25 years or more.

No permits are now granted for the excavation of basement or cellar areas within four feet of the curb line, this four feet being reserved by the Board of Public Improvements for city use for whatever purpose that space may be most available, and it is in this space that the subways will probably be placed.

WESTERN NOTES.

THE JONES BROS. ELECTRIC CO., Cincinnati, O., are about to bring out a new lightning arrester in three designs—one for station work, one for outside work, and one for electric cars.

ST. LOUIS ELECTRICAL SUPPLY CO.—Mr. E. Rubel, President of this company, was at the Auditorium, Chicago, for several days last week, looking after some important business for this company.

MR. CHARLES WIRT, of Wirt indicator fame, has just bought the entire stock, tools, fixtures and "good will" of the Wirt Laboratory, formerly owned by the Ansonia Electric Co. Mr. Wirt in addition to the manufacture of the well-known "Wirt" brush will now manufacture his indicator. Mr. D. B. Cheever for many years with the Ansonia Co. remaining in charge of that department.

THE UNDERWRITERS' HATCH DOOR CO., Chicago, of which Hon. Jno. W. Hepburn is president and general manager, are overwhelmed with orders for their automatic electric hatch doors, by which all the floors of an elevator shaft are automatically closed in case of a fire starting in any part of the building. This company is soon to extend its operations to all the larger cities of the United States.

P. & B.—The Metropolitan Electric Company have just taken the General Sales Agency for the P. & B. specialties, which include paint, armature varnish, electrical compounds, tape and Chatterton's compound. A large stock will be carried at their store and ware rooms, 186–188 Fifth Avenue, and prices will be made the same as from the factory.

CROUSE-TREMAINE CARBONS. Appreciating the demand which has existed for some time for a stock of high grade electric light carbons in Chicago the Electric Appliance Company have made arrangements to carry a stock of the celebrated Crouse-Tremaine carbons in Chicago sufficient to meet all reasonable demands for prompt shipment. They are also prepared to bid on large quantity orders for direct shipment from factory.

RAPID TRANSIT FOR NORTH CHICAGO.—Among the important measures that came before the Chicago Council at its last meeting was a proposition for extensive electric lines on the North side, which, it is claimed, will do away with the horse cars and transfer slips. The North Chicago Electric R.R. Co. made the proposition, and it has been recommended by the Council Committee on Streets and Alleys, North, D. H. Louderback, J. L. Cochran and others, who control the Evanston Ave. electric line, are said to be behind the scheme, although Mr. Cochran says the two companies are independent of each other. The discussion of the proposed ordinance in the council promises to be a stormy one.

MR. J. L. BARCLAY has moved into his new business quarters on the 16th floor, in the South end, of the Monadnock Building. The offices are well adapted for Mr. Barclay's electrical interests, and primarily selected by him for exploiting the Walker Manufacturing Company's electric railway and power machinery. The Central and Western departments of the Company's business are under Mr. Barclay's immediate supervision and management. Mr. H. McL. Harding, who is also interested in the above Company, has his headquarters for the Eastern department, in New York. While the general electrical interests of the Walker Manufacturing Company will receive the combined attention of Messrs. Barclay and Harding, all business directly connected with the Western and Middle States will be transacted at the Chicago headquarters. The appointment of District and Sales agents is now receiving attention. At this time, particularly, little trouble will be encountered in securing competent men. Mr. Barclay feels very much encouraged at the business outlook, notwithstanding the financial depression. Inquiry for the heavy types of generators and motors, such as the Walker Company manufacture, are numerous.

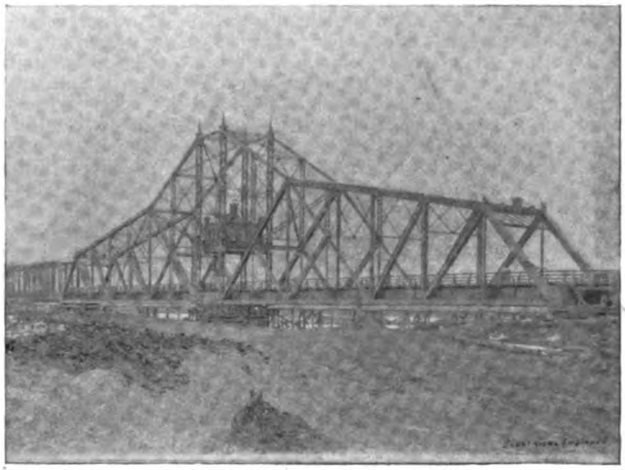
Electrical Engineer.
Vol. XVII. FEBRUARY 21, 1894. No. 303.

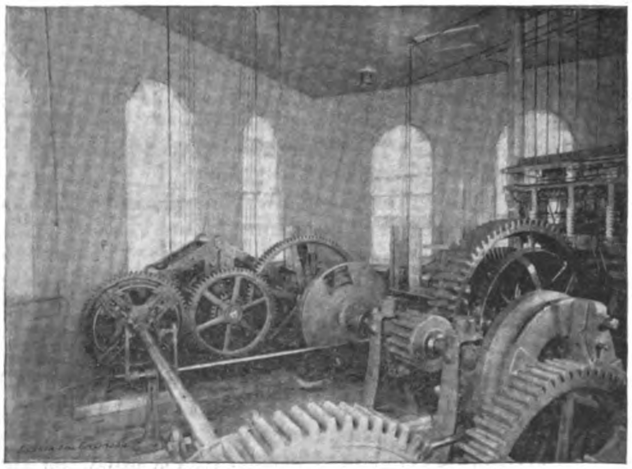


East Omaha and Council Bluffs Draw Bridge.

THE STORAGE BATTERY ON A DRAW BRIDGE, AT OMAHA.

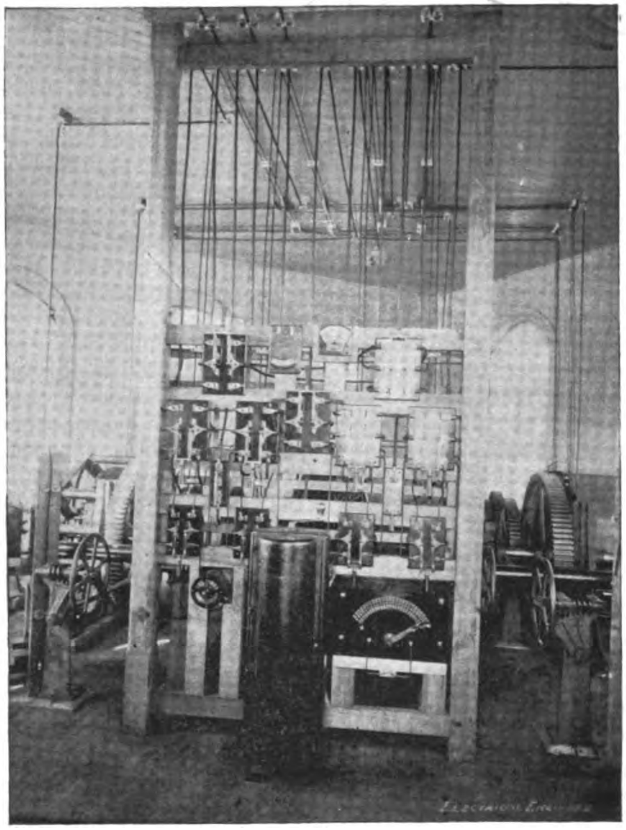
ONE of the most interesting applications of the storage battery is that recently successfully tested, and now in actual operation, on the 520 foot span of the Omaha Bridge and Terminal Company's draw bridge between East Omaha and Council Bluffs. The draw weighs between three and four million pounds and is swung in about four minutes by two Waddell-Entz motors of forty h. p. each, taking current from 384 cells of copper-steel alkaline storage battery arranged upon eight racks, each two in series, giving four distinct units. The motors, batteries, switchboard and gearing are all contained in a tower at the middle of the span forty feet above the road bed. The cells are charged from the trolley wire of the East Omaha Street Railway Company. The whole battery may be charged in series or it may be divided into two parts and each charged separately, and the machinery may be worked from one-half the battery independently of the other half if desirable.

The motors are geared to the main shaft that turns the bridge, and also to another shaft that operates the locking mechanism, both through the medium of friction clutches. The main shaft is cut at its centre and an equalizer is introduced to distribute the strain upon the large rack. The main gear wheel is five feet in diameter with a six inch face. An electric signal tells when the tracks on the bridge are in line, that the draw may be stopped exactly at that point.



View in Tower of Omaha Draw Bridge.

It is not supposed that the draw will be swung many times in the year for the passage of steamboats, but to keep it in good order the company will probably open and shut as often as once a week.



Switchboard in Omaha Draw Bridge Tower..

SENSITIVE CELLS.

In a letter to *Nature* of January 18th, Prof. Minchin describes some results obtained by him at Dara-mona House, Westmeath, by aid of Mr. W. E. Wilson's two-foot reflector in measuring the photo-electric effect of the light of the planets and fixed stars. The sensitive cells employed were seleno-aluminum-aenanthol cells, three square millimetres in area, and were connected with the telescope in place of the eye-piece. Clifton's form of the quadrant electrometer was employed. An electromotive force of 1 volt was represented by 460 scale divisions. Venus (quarter of disc) gave 40 divisions; Sirius, 9 divisions. Aldebaran gave no result.

THE ELECTRO-MAGNET; or JOSEPH HENRY'S PLACE IN THE HISTORY OF THE ELECTRO-MAGNETIC TELEGRAPH.—VII.

BY

Mary A. Henry

It should be remembered that Henry had not only discovered the relation between the intensity magnet and battery, but also that between the quantity magnet and battery. The arrangement just described was an intensity combination; Henry also tested the quantity combination. The apparatus for this, made jointly by Dr. Ten Eyck and himself, is in existence. It consists of a wooden frame, in which hung one of Henry's earliest quantity magnets now detached, but with the apparatus on a shelf attached to the frame is an insulated solid coil of short, very thick wire; there are two little magnets, with armatures so arranged that they can strike a hollow metal cone, used instead of a bell. This formed a convenient portable means of exhibiting the action of the electrical current. When Henry left Albany it was used by his successor, Dr. Ten Eyck, to illustrate Henry's discoveries, and was given by Dr. Ten Eyck to a favorite pupil, who is still the owner of the interesting relic. The reader knows the place the short quantity circuit holds in the telegraph.

We have glimpses of the telegraph in 1830 and the two following years through the eyes of Mr. Orlando Mead, late of Albany, who was one of Henry's pupils; he says:

"The older students of the Academy in the years 1830, 1831 and 1832, and others who witnessed his experiments, which at that time excited so much interest in this city, will well remember the long coils of wire which ran, circuit upon circuit, for more than a mile in length around one of the upper rooms in the Academy, for the purpose of illustrating the fact that a galvanic current could be transmitted through its whole length, so as to excite a magnet at the farther end of the line, and thus move a steel bar, which struck a bell. This, in a scientific point of view, was the demonstration and accomplishment of all that was required for the magnetic telegraph. The science of the telegraph was here complete. * * * Let us not forget that the click of the telegraph which is now heard from every joint of those mystic wires which now link together every city, and village, and post and camp, and station all over this continent is but the echo of that little bell first sounded in the upper room of the Academy."[1]

The following is another testimonial of an eye-witness to the operation of this telegraph. The Hon. Alexander W. Bradford, also a pupil of the Academy under Henry in 1831, says in an address, on the same occasion.

"And there is another professor, whose life has been spared, who rose with the sun to instruct his pupil, eager for knowledge; who, giving his heart and soul to the duties of the school, had yet time for exploring the deep paths of science; who, with his wires and silk thread, winding wires of insulated copper in the Commencement Hall of the Academy, patiently toiled his way to the demonstration of the magnetic power of the galvanic battery; and years before the introduction of the telegraph proclaimed to America and Europe the means of communication by the electric fluid. I was an eye-witness to those experiments and to their eventual demonstration and triumph."

Dr. James Hall, the distinguished geologist, (in the year he was president of the American Association) in a letter to Prof. Henry dated January 19, 1856, gives the following reminiscence.

Dear Sir:—While a student of the Van Rensselaer School, in Troy, New York, in August, 1832, I visited Albany with a friend having a letter of introduction to you from Prof. Eaton. Our principal object was to see your electro-magnetic apparatus, of which we had heard much, and at the same time the library and collections of the Albany Institute. You showed us your laboratory in a lower story or basement of the building, and in a larger[2] room in an upper story some electric and galvanic apparatus. In this room, and extending around the same, was a circuit of wire stretched along the wall, and at one termination of this, in the recess of a window, a bell was fixed, while the other extremity was connected with a galvanic apparatus. You showed us the manner in which the bell could be made to ring by a current of electricity, transmitted through this wire, and you remarked that this method might be adopted for giving signals, by the ringing of a bell at the distance of many miles from the point of its connection with the galvanic apparatus. All the circumstances attending this visit to Albany are fresh in my recollection and during the past years while so much has been said respecting the invention of the electric telegraph, I have often had occasion to mention the exhibition of your electric telegraph in the Albany Academy in 1832, (*Smithsonian Report*, 1857.). If at any time or under any circumstances this statement can be of service to you in substantiating your claim to such a discovery at the period named, you are at liberty to use it in any manner you please, and I shall be ready at all times to repeat and sustain what I have stated, with many other attendant circumstances should they prove of any importance.

I remain very sincerely and respectfully yours,

James Hall.

Professor Joseph Henry.

This telegraph of Henry's was properly an acoustic telegraph. The telegraph when first introduced into general use, in various ways, by dots and lines or printed letters, recorded its message on a moving slip of white paper; but the operator of to-day listens to its sound, and writes the message, and so it has come to pass that the telegraph is to-day again an acoustic telegraph, and its click heard everywhere is, in Mr. Mead's expressive phrase, *functionally and in truth* but the echo of that little bell which first sounded in that upper room in the Albany Academy.

BRENNER'S ONE-VOLTMETER METHOD OF SWITCHING DYNAMOS IN PARALLEL.

In order to ascertain when the voltage of a dynamo is at the right point for switching it on to a line in parallel with others, one of two methods is employed. In the first, two voltmeters are used, one to indicate the voltage of the line and the other that of the dynamo. Both of these instruments must be calibrated so that their readings correspond, and, if one of them give a false reading, as might easily happen, the generator may not be thrown on to the line at the right moment. In the second method, one voltmeter only is needed, which is connected alternately with the line and the dynamo by a switch. Though this method has an advantage over the first in requiring but one voltmeter, it has the disadvantage that the voltage of the line may change while that of the dynamo is being measured. This is a serious objection in electric railway power stations where the pressure on the line is continually fluctuating.

The advantages of each of these methods are retained and their defects overcome by an ingenious system devised by Mr. W. H. Brenner, the electrical engineer of the Montreal Street Railway Co., of Montreal, Canada. His arrangement, which requires but one voltmeter, has been used for some time in the Cote Street power station of the company, where it has given great satisfaction owing to its convenience and accuracy. By this system the generator to be switched in is connected temporarily to the line in series with the voltmeter in such a manner that the voltage of the dynamo opposes that of the line. The voltmeter then indicates the difference between the two voltages and thus the proper time to throw in the generator is ascertained.

The system as arranged at Montreal is shown in the accompanying diagram which represents the four generators in the station ready to be switched on to the line.

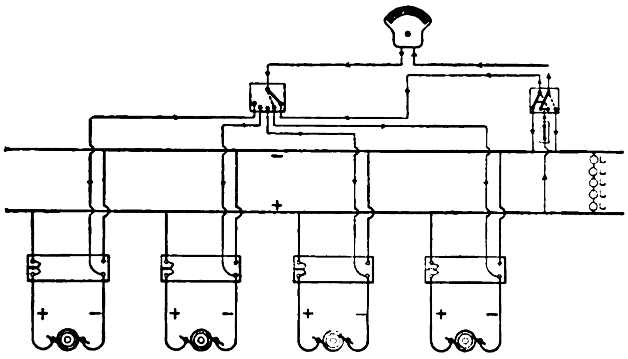
---

[1] Address on the celebration of the Semi-Centennial Anniversary of the Albany Academy, June 23, 1863.

[2] The rooms are about the same size, the upper one seemed larger, probably, because the lower was filled with raised seats.—M. A. H.

Lamps L L are inserted between the positive and negative bus in order that the circuits may be more easily traced. It should be explained that power is also supplied to the railway system by two other stations. One of the terminals of the voltmeter, which is a Weston station instrument, is connected with the line through a reversing switch and the other terminal is connected with a five-point switch, the first contact of which is connected with the reversing switch and each of the four others with the negative terminal of one of the generators. The positive terminal of each generator is connected with the positive bus by bridging this side of its main switch with fuse wire.

To indicate the voltage of the line, the five-point switch is placed upon the first contact, as shown in the diagram. When it is desired to throw in a dynamo, the connections of the voltmeter are reversed by the reversing switch; the new position of the switch being shown by the dotted lines. The voltmeter pointer will now move off the scale beyond the zero point. The five-point switch is then moved upon the contact connected with the generator which is thus connected to the line in series with the voltmeter. If these connections be made before the generator is started, the high resistance of the voltmeter prevents an appreciable current from flowing through the circuit.



ONE VOLTMETER METHOD OF SWITCHING DYNAMOS IN PARALLEL.

The positive terminal of the generator being connected with the positive bus, the voltage of the generator opposes that of the line. If the line pressure be the greater, a current will flow from the positive bus, through the generator and the voltmeter, to the negative bus. If the voltage of the generator be the greater, the current will flow through the voltmeter in the opposite direction, and the voltmeter will indicate the difference between the two pressures. In the first case, the voltmeter would indicate the difference in two voltages, if its connections be reversed by the reversing switch. When the voltage of the generator equals that of the line, no current will flow through the circuit and the indication of the voltmeter will necessarily be zero. In this way the proper time for switching in a generator may be ascertained with one voltmeter without any possibility of error, even if the pressure on the line be continually fluctuating.

EFFECTS OF THE STORM.

ONE of the most convincing arguments in favor of underground wires, if indeed such argument were necessary, was the severe storm which visited Chicago on February 19. While nearly all of the overhead lines suffered more or less from the effects of the blizzard, the underground service of the fire alarm, police telegraph, telephone, Postal and Western Union, as well as of the several electric light companies, met with no interruption whatever. Outside of Chicago the damage to the wires was rather severe, the greatest trouble to the telegraph lines being reported in the south-west, near Cincinnati, as well as in the neighborhood of Columbus, O. The Long-Distance service seemed to have suffered the least, showing the advantage of superior line construction, where underground work is impracticable.

THE GUTMANN INDUCTOR DYNAMO.

THE many different types of dynamo and motor produced, would make it appear that radically new types are scarcely to be expected. Occasionally, however, a new one does crop up, the most recent example of this kind being the machine of Mr. Ludwig Gutmann of Cleveland, Ohio. Hitherto most of the designs have been directed towards securing the most effective magnetic circuits, to obtain which, mechanical construction and other considerations have been frequently neglected to a considerable degree.

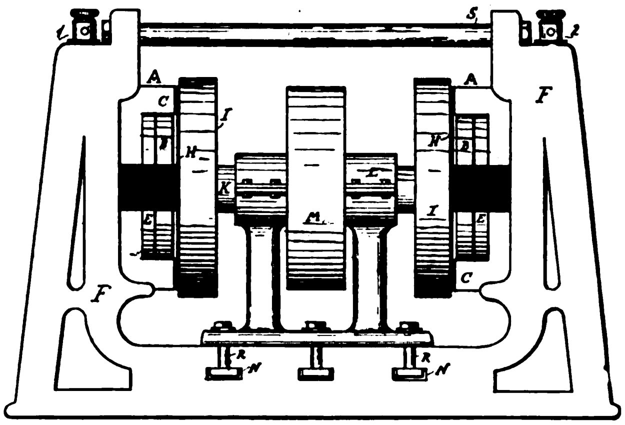


FIG. 1.—THE GUTMANN INDUCTOR DYNAMO.

This was specially noticeable at the World's Fair when observing the loading, unloading and mounting of dynamos, armatures, etc. Looking at these devices from a mechanical standpoint it was apparent that a heavy armature with its bearings far apart, which is necessitated by the interposed field magnets, has decided disadvantages. The two principal ones are, first, the great care required in handling such armatures to prevent damaging the insulation of the field magnet coils as well as armature in mounting or removing the same; and secondly, the constant watch that is required so that the bearings may not be worn down to so great an extent as to cause a considerable one-sided pull on the armature, resulting in springing of the shaft, and causing the revolving armature to rub against the field magnet poles. Another weak point not to be underestimated is that in most machines a heavy casting forming part of the field magnet has to be removed to obtain access to the armature. In the new type designed by Mr.

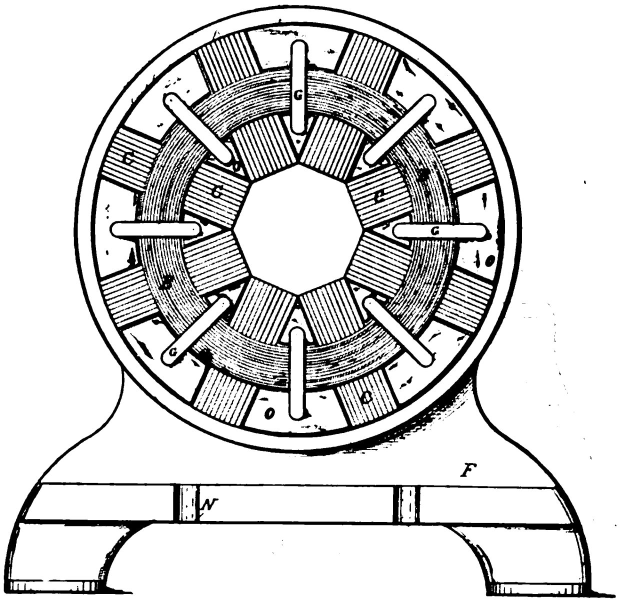

FIG. 2.

Gutmann these disadvantages seem to have been removed entirely. Fig. 1 shows a front view of the commercial machine in elevation.

The dynamo, which may be used as an alternator or continuous or polyphase current machine, belongs to the inductor type. That is to say, in this machine the armature winding as well as the field winding is stationary and only a small portion of the core is made to rotate and induces alternating currents in the armature windings by the increasing or decreasing resistance of the magnetic circuit, and, in consequence, a varying number of lines of force cut the armature winding. In Fig. 1, the field magnet is divided into two parallel structures A A, whose polar projections are grouped around a centre common in each structure, and each of them has but a single coil B for energizing all of the magnets C. This field winding, as shown in Fig. 2, is placed in a recess which is made large enough to also embrace the armature coil E. Both these coils are securely anchored in the main casting F by suitable cleats G in such a manner that even the cleats are below the surface of the projecting poles.

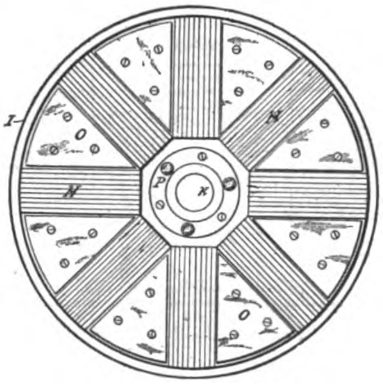

FIG. 3.

Between these two field magnet structures are located the two rotary core parts H, which, like the field structures, are laminated and mounted on a steel or bronze disc I and secured to the rotary shaft K, which rests in bearings L. The driving pulley M has a central position. By preference this machine, especially when used as an alternator, is separately excited but can be made to be self-exciting. The duplication of parts to the left and right of the pulley may lead one to assume that the alternator is a double machine ; however it may be said that the reaction of the armature winding on the field winding is such that a single side operated alone would not give satisfactory results unless modified to overcome the reaction just named. In the present machine it is overcome by suitable connection of the windings and by placing the core parts of the rotary element H so as to intersect the one with the other. The casting of the field magnet structure is shown to form in part the bed plate for the bearings and is provided with slots N enabling the bolting down of the independent armatures at the proper place and sliding them to one side at any time for inspecting the windings, without necessitating the removing of brushes, which are not required on this machine, nor the opening of any wire connections. The construction and location of the core parts and windings will be clearly seen in Figs. 2 and 3. To prevent the circulation of heavy air currents and consequent humming noise emitted by multipolar machines, blocks of china or wood O are placed between the core spaces.

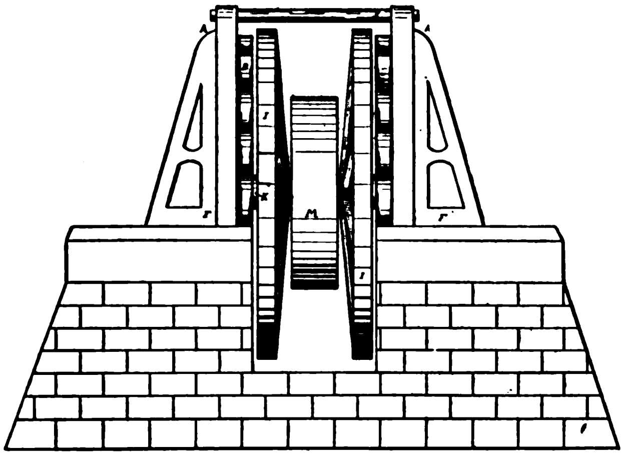

FIG. 4.

A distancing or thrust bearing P is provided at the end so as to keep the rotary iron masses far enough from the stationary core projections. The ends of the field exciting spools terminate at binding posts 1 (one of which covers the other behind it in the illustration), and similarly those of the armature spools are connected to binding posts 2. In the larger machines these parts are attached to the back of the main casting, where they are easily accessible and at the same time properly protected against mechanical injury by the projecting iron masses.

From Fig. 1 it will be evident that the movable part is in a perfect mechanical balance, that the armature shaft has the shortest possible length and that the central application of the driving force,—which, by the way, need not be a pulley but may be the gear of a turbine or the crank of an engine or the engine itself,—is the most suitable position obtainable, where the armatures themselves act as flywheels. The wearing of the bearings will have hardly any effect on the operation of the dynamo. It can never be the cause of a one-sided pull.

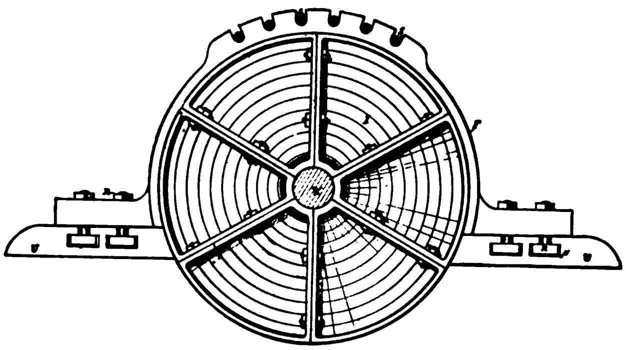

FIG. 5.

For the larger machines, Figs. 4 and 5, several modifications become desirable, as owing to the increased dimensions, the double coil construction becomes too cumbersome, especially if handling and shipping is taken into consideration. On this account the coils are subdivided and the cores are placed with the lamination in the direction of rotation so as to prevent heating by eddy currents, which in the form shown in Figs. 1, 2 and 3 are avoided by properly shaping the field poles; and lastly, instead of moving the armature or rotary structures, each of the field magnets is provided with means to be slid sidewise to enable a man to go between the armature and the field magnet. Fig. 4 represents the dynamo in front elevation and Fig. 5 is a view looking from the pulley to one side showing the armature in front of the stationary core parts and windings. The greatest stability is obtained by placing the armature bearings L on the ground as in common engineering practice. The armature core supports are built up in sections similar to a flywheel. To the side of the wheel are fastened the core block for changing the resistance of the magnetic circuit Z. The armature extends down into the pit while the field magnet cores and stationary windings are located in parallel planes properly secured and held apart at the bottom by the armature shaft and braced at the crown to prevent bending towards the rotary armature due to magnetic attraction. To admit inspection of the windings the T-bolts R are loosened at the side to be inspected as are also the bracing rods S in the crown of the field structure whereupon, by means provided on the bed plate U, such as screws and suitable handles, the field magnet structure slides sidewise on its bed-plates.

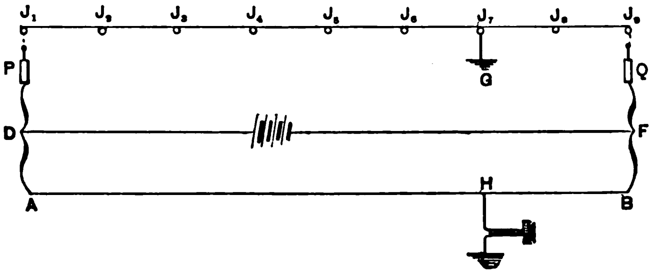
The many advantages of this construction for direct connected, or belt or turbine driven machines, are apparent; also that this type is well adapted for ship-lighting, as the engine can be mounted directly on the dynamo base plate, or vice versa. The central location of the driving force and the perfect balance obtainable render this type especially favorable for direct connection with engines, as the wear and strain on the latter owing to their position must be less than when the pull or twist is a one-sided one as must inevitably be the case if the dynamo is placed on one end of the shaft of an engine.

LOCATING TELEPHONE SWITCHBOARD TROUBLES.

BY

Jas. W. Manson

DIFFICULTY is often experienced by telephone men in locating grounded lines in multiple switchboards, more especially in those of the latest design, where the series method of arranging jacks has been abandoned, and what is known as the "bridging system" has been substituted.



MANSON METHOD OF LOCATING TELEPHONE SWITCHBOARD TROUBLES.

In the old style of multiple board, a line can be opened at any desired point, by simply inserting a blank plug, and trouble located in that way; but in the bridging board this is not possible, and the usual method employed is to examine successively every jack till the cause is actually located. Where the board has a large number of sections, this is tedious and unsatisfactory, the trouble-man being very apt to overlook the often almost microscopic contact in the attempt to quickly cover the entire board. It seldom happens that the fault is found before the majority of jacks has been inspected; and every jack unnecessarily looked at means just so much loss of time, not to speak of wear and tear to wiring due to the use of wedges.

The writer, having had occasion recently to clear such troubles in a board of the latest make, hit upon a plan for locating them, a description of which may be of service to those of your readers placed in a similar position. The principle involved is that of the well-known Wheatstone bridge reduced to its simplest form.

In the diagram J^1, J^2, etc., represents one side of the jacks of a line in its course through the board; A B is a naked wire extending the length of the switchboard and joined at its extremities to the plugs P and Q; and D F a battery wire branching to the naked wire and the plugs as shown.

Suppose the plugs inserted in the first and last jacks of a line having a ground at G, and that a receiver grounded on one side has its other side free to touch the naked wire at a point H, opposite to G; then, D P G : D A H : : G Q F : H B F; or the same conditions found in a balanced Wheatstone bridge. By tapping with the free side of the receiver on the naked wire at intervals along its length, the spot where a balance can be obtained is easily and quickly found.

Experience has shown the writer that this is a very delicate yet practical test. Crosses and short-circuits may also be located in the same way by grounding one of the lines in trouble and locating in the other. A neater arrangement to give quicker results may be used by bringing D and F to a short length of fine German silver wire, divided into proportional parts, and striking a balance on it, as before; the principle is the same.

COPPER ECONOMY OF ALTERNATING CURRENT SYSTEMS.

BY

Chas. Steinmetz.

SINCE quite erroneous statements are frequently made, even by otherwise well informed people, on the copper economy of alternating current systems, i. e., the amount of copper required to transmit a given amount of power with a given loss of energy, it may be of interest to investigate this question somewhat further. Before discussing different systems of transmission, however, it is necessary to establish a basis for the comparison, and this can only be equality of potential, for it would obviously be useless to compare, for instance, a 1000 volt three-phase, with a 2000 volt single-phase system, since it is evident that a system of higher potential will be more economical in copper.

When trying to compare different systems of transmission we meet with the further difficulty, that in some systems different potentials exist. So, for instance in the ordinary Edison three-wire system the potential between the neutral and outside wires is only one-half the potential between the outside wires; or in the interlinked quarter-phase system, i. e., the quarter-phase system with common return, the potential between the outside wires is 41.4 per cent higher ($\sqrt{2}$) than the potential per phase. We have to decide, therefore, which of the different potentials shall be used as the basis of the comparison.

In long distance transmission, in transformers, and all high potential apparatus, the practical limit set for the potential is merely due to the electrostatic strain on the insulation and the liability to disruptive discharge caused thereby. Since the electrostatic strain, and therefore the reliability of the system—other things being equal—depends upon the maximum potential existing in the system, the only proper basis for the comparison of different systems in this case will be, equality of maximum potential existing in the system.

Again, in other cases, as, for instance, power distribution for small motors, the danger to life is the limiting element. Here again it is the maximum potential which is the determining element. Take, for instance, an interlinked quarter-phase system, with 500 volts per phase, i. e., $500 \times \sqrt{2} = 707$ volts between the outside wires. Such a system will obviously be more dangerous than a 500 volt single-phase system, and will indeed be equivalent in danger to life to a 707 volt single-phase system. Hence in this case the only proper basis of comparison is the equality of the maximum potential also.

In some cases, however, especially in the low potential networks supplying incandescent lamps, the potential is necessarily so low as to cause practically no strain on the insulation, nor any serious effects in touching live wires;

but since lamps of more than 110 volts are not yet used in general practice, in this case the ability of supplying apparatus requiring a definite low potential must be the standard of comparison; that is, in this case, the different systems have to be compared on the basis of equality of the minimum potential in the system. We shall therefore have to carry the comparison through on the basis of equality of maximum potential (long distance, transformer and motor work), as well as on the basis of equality of minimum potential (low potential incandescent lighting).

Table I.

COMPARISON ON THE BASIS OF EQUALITY OF MAXIMUM POTENTIAL IN THE SYSTEM.

To transmitt the same power over the same distance with the same loss of power, that is, with the same efficiency, the amounts of copper required are:

2 wires, single-phase system	**100**
3 wires, three-phase system	**75**
Interlinked quarter-phase system	**145.7**
Interlinked quarter-phase system with 3 equal wires	**150**
4 wires, independent quarter-phase system	**100**

If in a given system of electrical transmission we double the potential, the same energy will be transmitted by one-half the current. Since the loss in the transmission line is equal to $C^2 R$ the resistance may be quadrupled to give the same efficiency, i. e., only one-quarter the copper is required, or, in other words:

The amount of copper required to transmit a given power with a given loss of energy is inversely proportional to the square of the potential, other things being equal.

The simplest way to compare different systems of alternating current transmission, as single-phase, three-phase, etc., is to bring them to comparability by reducing them to their component one-wire systems in the following manner:

The single phase system with two wires of a difference of potential e can be considered as consisting of two circuits of one wire each and a potential $\frac{e}{2}$, i. e. the potential between one wire and the neutral point or centre.

The three-phase system with three wires and a difference of potential e between the wires, consists of three circuits, each of one wire and of the potential $\frac{e}{\sqrt{3}}$, the potential between the wire and the neutral point, which in this case is the centre of gravity of the equilateral triangle formed by the three line potentials.

It follows from this at once, that the amount of copper required to transmit the same power with the same loss of energy in these two systems is inversely proportional to the squares of the potentials of the component one-wire systems, i. e., as $\left(\frac{1}{2}\right)^2 \div \left(\frac{1}{\sqrt{3}}\right)^2$ or as 4 is to 3. This means: *That the three-phase system requires* $\frac{3}{4}$ths *or 75 per cent. of the copper necessary in a single phase system of the same potential.*

The quarter-phase system with independent circuits, i. e., with four wires, requires the same amount of copper as the single-phase, since it is nothing else but two independent single-phase systems. Using one wire as a common return for both phases the current in this wire will be increased by $\sqrt{2}$; the loss of energy in this wire being doubled it will therefore be the same as before in the two wires, so that the efficiency is the same as with independent circuits; in other words one of the wires, or 25 per cent. of the copper is saved, and an interlinked quarter-phase system, or quarter-phase system with common return requires 75 per cent. of the copper necessary for a single phase system, having the same potential as the potential of the quarter-phase system per phase.

If, however, the potential per phase of the quarter-phase system equals e, the potential between the outside wires is $e \times \sqrt{2} = 1.414\ e$, and if compared on the basis of equality of maximum potential the interlinked quarter-phase system of the potential e per phase has the same maximum potential, i. e., the same strain on the insulation as the single-phase system of potential $e \times \sqrt{2}$. Since this single phase system requires only one-half the copper of the single-phase system of potential e, the interlinked quarter phase system requires not 75 per cent. but 150 per cent. of the copper required in the single phase system to transmit the same power with the same loss of energy, when compared on the basis of equality of maximum potential in the system, i. e., on the basis of equality of the strain on insulation and danger to life.

In this case, where for the interlinked quarter-phase system three equal wires are used, the current density of the common return will be greater than in the outside wire, i. e., the disposition of the copper will not be the most economical. Making the cross section of the common return 41 per cent. larger than that of the outside wires, i. e., using the most economical arrangement of equal current density in all three conductors the amount of copper required in the interlinked quarter-phase system is reduced from 150 per cent to 145.7 per cent (more exactly $\frac{3 + 2\sqrt{2}}{4}$).

Table II.

COMPARISON ON THE BASIS OF EQUALITY OF MINIMUM POTENTIAL ON THE SYSTEM.

To transmit the same power over the same distance with the same loss of power, that is, with the same efficiency, the ratios of copper required are:

2 wires, single phase		**100**
3 wires:	**Edison 3-wire, single phase system, neutral = ½ cross section of outside wires**	**31.3**
	Edison 3-wire single phase system, neutral = full cross section of outside wires	**37.5**
	Interlinked quarter phase system	**72.9**
	Three-phase system	**75.0**
4 wires:	**4-wire single phase system, inside wires = ½ cross section of outside wires**	**16.7**
	4-wire single-phase system, inside wires = full cross section of outside wires	**22.2**
	Three-phase system with neutral wire	**33.3**
	Independent quarter-phase system	**100.0**
5 wires.	**5-wire single-phase system, inside wires = ½ cross section of outside wires**	**10.9**
	5-wire single-phase system, inside wires = full cross section of outside wires	**15.6**
	Independent quarter-phase, with common neutral.	**31.3**

In the low potential distributing networks for incandescent lighting, where the proper basis of comparison is equality of minimum potential in the system, a considerable saving of copper is effected by the use of multiple wire systems, as for instance the Edison 3-wire system. Replacing the two-wire system by three, four or five wires, with the same potential between the adjacent wires the potential between the outside wires is increased 2, 3 or 4-fold, and thereby the theoretical amount of copper required reduced to one-fourth, one-ninth and one-sixteenth. In practice somewhat more copper is required, since the neutral or intermediate wires must have some cross section also. Thus in the Edison three-wire system theoretically, i. e., for the two outside wires, one-fourth the copper is required as for the two wire system. If, however, the neutral wire is made of the same cross section it increases the amount of copper by 50 per cent., to three-eighths; or if the neutral wire has one-half the cross section of the outside wire it increases the copper by 25 per cent. to five-sixteenths. In this case the interlinked quarter-phase system has to be credited with 75 per cent. and 72.9 per cent. respectively, of the copper required in the two wire system.

It is hardly necessary to explicitly give calculations for all the different arrangements, since anybody who understands multiplication and division can easily derive the results, and it may be sufficient to refer to the accompanying tables which may be of convenience for reference in deciding upon the choice of the proper system.

Coming now to the comparisons of the continuous current with the single phase alternating current we see that the copper economy of both is the same, if the comparison is made on the basis of equality of effective potential as for low potential net work and probability of danger to life.

In high potential lines where equality of maximum potential is the basis of comparison the single phase current of potential e has the maximum potential (with the assumption of a sine wave) of $e \times \sqrt{2}$, and therefore compares with a continuous current potential $e \times \sqrt{2}$; that is, the continuous current circuit can be worked at a 41 per cent. higher potential and then requires only 50 per cent of the copper of a single phase alternating current, under the condition of the same *electrostatic* strain on the insulation.

This comparison is not fair, however, since the continuous current causes an electro-chemical strain on the insulation by electrolysis which does not exist in alternating current circuits but is in continuous current circuits probably more severe than the electrostatic strain; besides, since the continuous current is practically out of the question anyway for high potential work the comparison of the equality of maximum potential between continuous current and alternating current is of little interest. I need only add that these numerical results are identical, so far as they go, with the figures given by Kapp, and others who have made a careful investigation of this question.

ELECTRICITY AS A MOTIVE POWER IN THE DENTAL OFFICE.

BY

Thos. H. Berry

VERY few electricians have given this branch of motor work any thought, and many of those who have attempted to supply the dentist with motors have failed more or less because they failed to understand the requirements, and the peculiar and severe tests that a dental motor is put to. Others have given it up because the small demand and small power used does not warrant them in spending much time in its study and application.

The operation of dental apparatus is perhaps one of the severest tests of an electric motor. There is no other use that a motor is put to (unless it be in operating elevators), where it would receive as sudden changes and be called upon for such varied requirements as in the office of a busy dentist. Let us see what is done: A hundred times a day, or more, it is started, stopped and reversed under different conditions. For instance, it is started suddenly without any load at full speed, then the load is thrown on suddenly as when grinding with a large wheel in the mouth. The load is then thrown off all at once and motor stopped suddenly from full speed, or perhaps reversed from full speed to full speed in opposite rotation. Again it is stopped suddenly while running at full speed; I mean, stopped on one half a revolution while running at perhaps 2,000 revolutions per minute, as is necessary when the drill becomes caught in the rubber or between the teeth. Here we have to overcome the sudden electric strain on the motor and also the heavy sparking at the switch and brushes. Again it is often necessary to reverse the motor while running at full speed and perhaps without load. Here we have the counter electromotive force of the armature to contend with, for the higher the speed and the lighter the load, the greater the counter E. M. F. Again, we want to run at very slow speed and still have good torque and good regulation of power. The next moment we want very high speed and good power.

One who has not been brought face to face with all these various requirements would at first thought say, "It is not much of a trick to set up a ⅛ or ⅙ h. p. motor for a dentist." And many electricians have attempted to supply the dentist with what they supposed was all the dentist needed; and thus the dentist has not used the electric motor as much as he would have done, had it been all he could ask for. Another feature which makes success more difficult is the complication of switches, rheostats, friction clutches and motor generators, where the power is regulated by throwing resistance into the generated current circuit. All of these tend to confuse the dentist and make the combination more apt to get out of order and be thrown aside for the old foot power.

After making it a study for several years and having the advantage of being a dentist myself and so knowing what the requirements of such a machine are, I am able to lay down a few useful points, which I have proved in practice to meet the requirements, and which I hope may help the electrician to meet the demands of the dentist, and also furnish food for thought on the subject so that my profession may reap the benefit of the progress made in electricity.

Speaking now of a motor used for operations in the mouth and operated on the 110 volt continuous current, a good, well-made, quiet running, shunt wound, ⅛ or ⅙ h. p. is all that is required. With this there is needed a switch, preferably operated by the foot, that will handle the motor through a rheostat. The usual way is to place the rheostat in series with the armature for variations of power, and the usual way to reverse is to reverse the current in the armature. The quick stop is usually produced by a cone or magnetic clutch in series with the fields.

My objection to the first and last are these: With the rheostat in series with the armature we do not get the same relative variations of regulation and power throughout the different degrees of power. For instance, on the slow speed we have the armature partially magnetized, revolving in a saturated or highly magnetic field; we do not get the same relative regulation and torque on slow speed as on full speed, because the relation between the current in the armature and field is vastly different from that at full speed.

The cone or magnetic clutch throws the work on and off the motor suddenly without in any way preparing the motor for the sudden change; besides, it adds complication to the combination of parts. It also allows the motor to be suddenly reversed without first stopping it, which is, as we all know, not a safe plan to follow, especially with small motors on high voltage circuits. The better way is to employ a switch that will operate in the following way: At the first move of the switch the fields and rheostat are thrown in series, and, at this same point, the armature terminals in short or closed circuit. At the next move the armature and fields are thrown in shunt, and these in series with the second step of the rheostat; here we have the slowest speed, and the armature and fields are both receiving their relative amounts of current. The regulation and torque is in the same proportion to the power as it is at full speed. The next step of the rheostat gives more power, and so on up to full power. Now, to suddenly stop at this point, the rheostat is cut in to the first step where the fields are in series with the whole resistance and the armature on short circuit; at this point we have the armature revolving in a partially magnetized field. It really now is a dynamo, generating a current through the armature closed circuited, and this current is what was the counter current of the motor. As it now requires power to continue the generation of this current, and as the armature is receiving no outside power other than its momentum, it suddenly comes to a stop. The next move throws the fields and rheostat in series off, with little or no sparking with so small a motor. The next move back or opposite, again throws the fields in series with the rheostat and armature closed circuited. The next throws in the armature in shunt, but in reverse current; here we have slowest speed in reverse rotation, and the next step gives more power; and so on, up to full speed.

By this method it is impossible to reverse the motor from full speed ahead to reverse full speed without throwing in the rheostat, short circuiting the armature, and thus overcoming the the counter E. M. F., and at every move it puts the motor in its best condition for work at that speed or power.

At the time the armature is on closed circuit, the fields are only slightly magnetized, as the rheostat is in series; hence we do not get the heavy sparking at the brushes that we would by closing the armature in a strong magnetic field. The shunt and relation between the fields and armature remains the same at all differences of power, as the rheostat is in the main and not in the shunt. At the same time it converts any good make of shunt motor into a good dental motor without any addition or change to the motor. All the variations are produced electrically in the motor, and none mechanically as by electric brakes or clutches. In fact, there is no friction or rubbing of parts during quick stop, and so no noise or clicking of a magnetic clutch. All is so simplified that the motor is in just as favorable a way to operate under the required variations as it is for fan work or any constant load.

I have been operating on this plan for four years, and it has proved to be very practical and satisfactory in its operation, and very sensitive to variations at all stages of the dentist's work.

THE COPPER-ZINC ACCUMULATOR.—IV.

BY

Paul Schoop

THE necessity of a porous partition between the anode and the cathode has already been alluded to. As is well known, such a membrane does not contribute to the simplicity of the apparatus. Desmazures employs parchment paper in his cell; Phillips and Entz cover the copper cable with a layer of cotton. Experience with the lead accumulator has shown that the capacity of the same cell increases if either the positive or the negative plates are wrapped in envelopes of asbestos or parchment paper or similar sheets. The rapidity of diffusion or the rate at which the liquids inside and outside of the electrode mix is decreased and since the charged active material alone does not yield any current, unless there be present the proper amount of the necessary electrolyte, it will be seen that the porous partition is rather a drawback. Besides, the durability of parchment paper or cotton with strong caustic potash solution is not above suspicion.

In this field, Professor Aron of Berlin invented his mercury-zinc accumulator about ten years ago. This combination consists of a cathode and an electrolyte precisely the same as that of the copper-zinc battery, but instead of the suboxide of copper as an active material oxide of mercury is used. This means a decided improvement in several directions. First, there is no further necessity for the porous partition. Like the oxide of copper, the oxide of mercury is not perfectly insoluble in the caustic potash solution; but even if a trace of mercury should be dissolved, this would have no deleterious effect on the zinc electrode. In contact with the zinc plate, mercury will be deposited on it and thus amalgamate the zinc and protect it against local action. This is just contrary to what we have seen in the case of copper, traces of which give rise to a tremendous local action on the zinc plate. Furthermore, the voltage of the mercury-zinc accumulator is far above that of the copper cell, being about 1.40 volts as against 0.85 volts, for the latter. It would therefore seem, other things being equal, that the mercury cell would at once surpass everything else in this line. But unfortunately the conductivity of the oxide of mercury, as it is formed by the electrolytic action during the charge seems to be very low and thus hinders its practicability. Instead of suboxide of copper, oxides of manganese have been also proposed as active material (L. von Orth, Leipzig). Although it is obvious that manganic acid will be formed during the charge, still, if this body should reach the zinc plate, no local action will occur.

The circulation of the electrolyte is another important point in connection with the alkaline accumulator. While Desmazures proposes to stir up the electrolyte mechanically from time to time, Messrs. Phillips and Entz have devised a heating method, which, it is claimed, performs the necessary mixing of the liquid. When the discharge of the battery is going on, the solution of zinc, formed on the zinc side, sinks to the bottom, being heavier than the ordinary solution in the cell. If afterward, the battery is charged again, very little zinc is found on the upper part of the cell and, of course, the deposition of zinc is carried on very irregularly over the whole surface of the plates. The maintenance of an automatic, good, reliable circulation of the liquid, is, according to the opinion of the writer, indispensable with a reliable working of this type of battery. Even with the lead accumulator, great success has followed that little wrinkle in relation to circulation. The rules, given for charging a Tudor battery, contain the following: "Each charging has to be carried to the end, until *large bubbles* of gas appear abundantly on the surface of the liquid."

In practice it will be found that it always takes 20 to 30 minutes from the beginning of the development of gas to reach that point, and the gas bubbles evolved set up such a strong circulation of the whole liquid in the vessel that it is mixed wonderfully well. This rule, followed up regularly, has most likely more influence on the life of the brown plates than the peculiarity of the construction of the plates, given a certain solidity of the lead support to begin with.

It seems to the writer, however, that the kind of circulation obtained by heating the vessels is not of the most reliable kind and that further progress could be made by applying proper devices for a good circulation, which must of course be simple, automatic and inexpensive.

Means for keeping out dust and the carbonic acid of the air are also pertinent with this type of battery. A layer of paraffin oil does not prevent the absorption of carbonic acid by the caustic potash. This may be easily seen by exposing to the air for some days a caustic solution, absolutely free from carbonates, and covered with a layer of half an inch of paraffin oil. There will not be much difference between this solution and another one of the same initial composition, but not covered at all by paraffin. Paraffin oil, like water, alcohol and a good many other bodies, also absorbs carbonic acid and, of course, gives it off to the caustic potash and absorbs again, and so on. The effect is as if the carbonic acid went right through the paraffin, and just as it would do with a porous diaphragm. As soon as the liquid has absorbed a certain quantity of carbonic acid, zinc is precipitated and eliminated in the form of basic carbonate of zinc. After a certain time, a decided decrease of the capacity of the cell will be noticed and it will be necessary to renew the electrolyte by a fresh alkaline solution of zinc. In this respect, only an airtight cover with a gas-valve will protect the liquid sufficiently.

The Resistance of the copper-zinc accumulator varies greatly with the temperature, much more so than that of a lead cell. It is quite considerable at temperatures near the freezing point and quite small at high temperatures. At 130 degs. the resistance is about double what it is with a lead accumulator of the same capacity in watt hours. The efficiency of the battery depends, of course, upon the resistance and is, therefore, highest at the very highest possible temperature. Since the resistance is made up of several components (resistance of the electrolyte, resistance between the zinc layer and its support, resistance between the porous copper and its supports, resistance caused by the porous partition, etc.), the above remarks are very general.

The Capacity depends also on the temperature of the cell. With the lead accumulator one may say that between temperatures of from 32 to 68 degs.,—the capacity of the cell being 100 at 68 degs.—for each degree downward the capacity diminishes ½ per cent. At 32 degs. F., the capacity is only about 80. Now, the same thing is true even to a greater degree in the case of the copper cell. There is good reason to believe, that this decrease of capacity depends main on the state of fluidity or viscosity of the electrolyte. One can imagine that the lower the temperature the thicker electrolyte becomes until at last it is solid; at this point, no capacity at all would be found in the cell.

THE WESTON TELEGRAPH RELAY.

The remarkable sensitiveness of the Weston voltmeter and its accuracy in determining small differences of potential has led the inventor, Mr. Edward Weston, to adapt it to telegraphic work, and a patent has recently been issued to him covering this novel application of a well-known device, slightly modified, as shown in the accompanying engravings. Here Fig. 1 shows the plan of the instrument, Fig. 2 is a sectional view, Fig. 3 shows the movable coil and Fig. 4 is a diagram of the circuit.

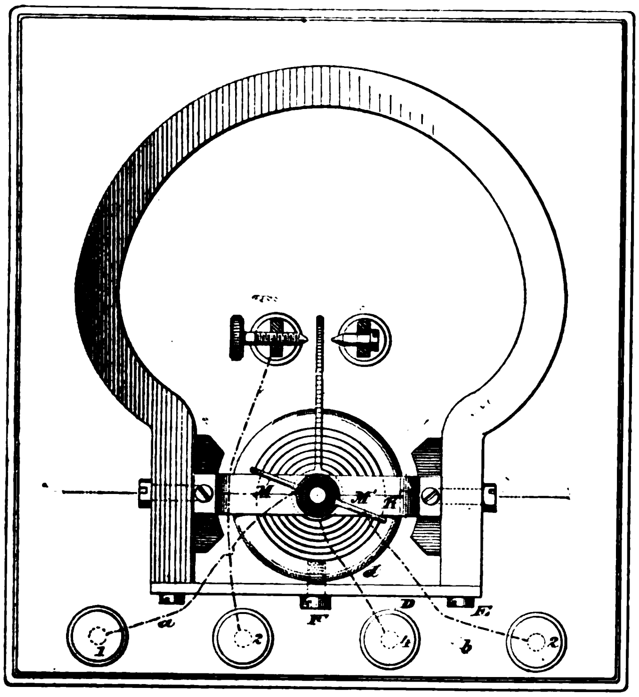


Fig. 1.—The Weston Telegraph Relay.

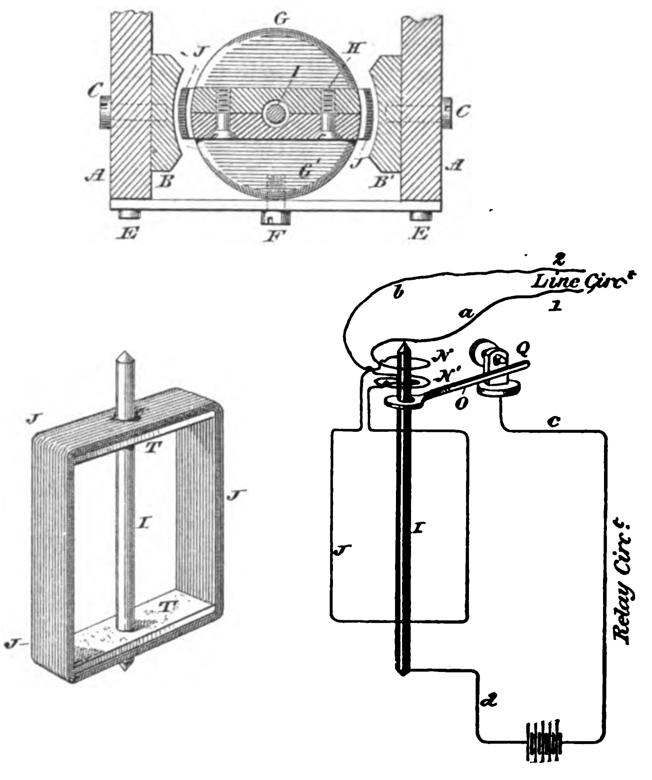
When the current comes over the line circuit, the coil J tends to set itself in a position transverse to the lines of force of the magnet A, and it therefore rotates on its pivots, and so moves the contact arm O into contact with the adjustable contact stop Q, thus establishing a local or relay circuit. While the movement of the coil depends as before upon potential difference, the extent of movement is not measured, nor is it material so long as it is sufficient to move the circuit-closing arm of the relay circuit into and out of contact with its stop. The main thing needed is great sensitiveness of the coil, so that it will respond instantly and quickly to any current, however small, which may pass through it. It, therefore, becomes important not to provide the coil with any means tending to retard or check its motion. It is also desirable to make the coil as light as possible, so that the retarding effect of its own inertia will be reduced. With these objects in view the coil, as represented in Fig. 3, consists of a helix wound upon two transverse bars T of paper or light metal, which are secured to the pivot shaft I. The vertical portions of the coil, therefore, which enter the field, are merely parallel strands of fine wire. The resistance of the coil to its impressed motion due to the current is, in this way, reduced to a minimum.



Figs. 2, 3 and 4.—The Weston Telegraph Relay.

The great advantage claimed for this instrument is the exceedingly small amount of current required for its operation. The measuring instruments of the same type are so extremely sensitive and accurate that, according to Mr. Weston, it is safe to say that this apparatus will work under a current strength of much less than one ten-thousandth of an ampere. According to Mr. Weston the new relay will permit the working of longer main lines with less battery power, and line conductors of smaller cross-section, coupled with greater certainty and accuracy of operation.

THE PAN-AMERICAN TELEGRAPH LINE.

A syndicate has been organized for the purpose of constructing a Pan-American telegraph line to extend along the Pacific coast from Victoria, British Columbia, to Santiago, Chili, passing through the United States, Mexico, the Central American States and the Pacific coast countries of South America.

THE WASHINGTON CONVENTION.

As a place at which to hold a winter convention, it must be admitted by everybody that Washington is hard to surpass. At any time it has countless points of charm and interest, but when Congress is sitting and the whole atmosphere of the town is athrob with national politics and controversies, he is indeed a dull man whose pulse is not quickened on thus finding himself at the very heart of affairs, participating at will in historic scenes and shouldering celebrities at every turn.

The National Electric Light Association will meet in Washington next week, and the wisdom of the choice is already seen in the promise of an unusually large attendance. Not only is the National Legislature engaged with questions of the most vital importance, and debating them with an ability that certainly has not been excelled of late years, but the national electric light legislature has also a good many large topics for its earnest and careful consideration. The industry throughout is on the move, and the returning times of normal prosperity find it confronted with new issues. The industry to-day is freer than before. Never was the power of the parent companies less; never was the strength of the local companies acting together greater; never was there a fainter desire on the part of the supply houses to dictate, or even suggest, the lines upon which the Association should be run.

It is already known, as we have said, that the attendance will be large, but if any of our readers who ought to go are still undetermined, we urge them to make up their minds at once to the trip. These are still days of economy, but better times are near and the expense is so slight as to bear no relation to the good that can be derived for meeting old friends, making new, sizing up the situation, and imparting as well as receiving the cheer and encouragement with which to speed the arrival of the next long, solid era of prosperity.

EXTINGUISHING LIBERTY'S TORCH.

Once again it is proposed to quench the torch of the Bartholdi Statue of Liberty that stands so conspicuously at the entrance of New York Harbor, and faces the incoming stranger who has just braved the terrors of the Atlantic for the sake of a new home. The Secretary of the Treasury has virtually pronounced the light of Liberty a nuisance. The Lighthouse Board has informed him that the statue as a beacon is of no use whatever, standing on no range and being too far inland. Moreover the generating plant has run down, or been allowed to deteriorate, and the appropriations are insufficient for work really needed elsewhere. The secretary therefore wants the House of Representatives to order the extinction of the Statue as a beacon.

This strikes us as a rather lame and impotent conclusion to arrive at in view of the fact that the Statue is the gift of a friendly nation and can certainly be made ornamental should it perchance fall short of utility. New York has been rather unlucky in its attempts to get first class electric beacons. The tall tower at Hell Gate was abandoned because its light was too strong and now the Statue of Liberty is to be given up because its light is too weak. It appears that the cost of maintaining Liberty now is less than $10,000 a year. That ought not to tax the Lighthouse Department very severely; but if it does, we believe the Franco-Americans on each side of the Atlantic would raise enough money to create a fund for the work. Besides the lighting of Liberty might be improved both as to operation and as to the form of the light. It might be possible to light the Statue with current sent through a cable, and thus dispense with the island plant. It seems to us that the Statue itself has never been quite successfully handled. Why would not a couple of search lights be an improvement over the present method? Or perhaps the whole figure could be outlined. We have no definite plan in mind, but in conveying to our readers what seems to us to be a not very satisfactory piece of news, we suggest that in the rehabilitation of the Statue of Liberty as a beacon there may be both opportunity and glory for some of them.

REPARATION OR RECONSTRUCTION OF INCANDESCENT LAMPS.

Electrical litigation has served to establish or confirm more than one principle in law and the recent decision of the Circuit Court of Appeals in the case of the Edison Electric Light Co. (General Electric Co.) vs. the Davis Electrical Works, brings out a rule which has a wide bearings on apparatus involving devices subject to "combination" claims. Considering the second claim in the patent, the one in controversy, the Court takes the view that the only new element in the combination is the carbon filament; and that this in use in a vacuum represents the entire advance from the state of the art, so far as that claim is concerned. After reciting and discussing a number of previous decisions on the question of what constitutes *repair* as distinguished from *reconstruction* of patented mechanical devices, the court comments on the arguments and affidavits submitted and cites that of the appellants who argued that if the injunction were allowed to stand it would give the complainants the same benefit as though the patent contained a claim for the filament alone. While admitting this contention, and citing the Bell telephone claim as a case in point, the Court nevertheless holds that if the new element in a combination is associated in the claim with additional elements which, in the state of the art, there is no practical method of replacing by others, the patentee obtains the same practical advantages as though this new element had been claimed alone,—at least until the art makes new discoveries; but the patentee, it holds, ought not to be deprived of his just rights because under some circumstances he gets incidental advantages beyond what he expressly bargained for. But it seems that one of the principal affidavits presented by the defendants had an effect upon the judicial mind exactly opposite to that which it was intended to have. This affidavit likened the renewal of the filament in an incandescent lamp to the replacing of the wick in an oil lamp, and further compared the opening of the glass globe for the insertion of the filament to the removal of the glass chimney in order to facilitate the insertion of a new wick. The Court holds, contrarily, that so far from the filament being the mere wick, it is itself essentially the lamp, that is, the electric lamp of Edison. "In essence, the filament, duly charged, is the light-giving thing. It can give light without the glass receiver or the vacuum, though it does it better and longer with them." On these and other grounds the Court holds that the injunction issued from the Court below must be allowed to stand and thus the question of incandescent lamp repairing would appear to be for the time being determined, so far as the District of Massachusetts is concerned. We have an idea that the question of the repair, even reconstruction, of patented devices is barely settled yet. Probably nearly all the electric light and electric railway companies in the country to-day are repairing and reconstructing, frequently, patented devices that compare broadly with the lamp. Some of us remember the time when the old parent companies insisted on doing all the repairs at terrific prices. They don't now.

THE AMERICAN GONDOLA.

One of our articles this week illustrates and describes the successful appearance of an American electric launch upon the waters of the Adriatic, at Venice. The launch was taken from the World's Fair lagoons after successful service and lots of hard work, and carried to Venice, where its operation has been witnessed with intense interest by the whole population, which has a most natural curiosity to see how the new comer can compete with the historic gondola. The scene depicted in our illustration, showing the launch on the Grand Canal, off the Doge's Palace, is full of suggestiveness, and we can readily imagine that many a poor gondolier fears to find his occupation gone. It is the intention, we are informed, to put a number of these launches on the canals of Venice. No objection can be raised to them, even on the score of uncomeliness, for as they are now, without any pretence at special splendor, the launches have fine, graceful lines and they can, if necessary, be made in the shape of gondolas, just as the first railway carriages simulated in their curves the outlines of the old stage coaches. Moreover, the gondolier, whose present task is a hard one, can obtain much easier employment, if he will, handling a launch with a few turns of the wrist.

In this country, it may be said, the future of the electric launch is now well assured, both by the brilliant demonstrations of a practical nature at the World's Fair, and by the intelligent interest now being taken in them by some of our wealthiest amateurs. A new thing sustains no harm by having fashion enlisted in its behalf. Naphtha launches have been a most deserved success, and there are now a great many afloat, with the likelihood of more to come; but our conviction is strong that the electric launch is destined to be par excellence the American gondola.

MYSTERIOUS ELECTRIC LIGHT FIRES.

The "drive" which the Fire Underwriters of New York have recently been making on electric lighting and electric railways, as a cover for an excuse to raise insurance rates, will probably lead to no more results than have similar attempts in the past. The desperate character of the latest attempt, is shown by the fact that an increased rate is put on buildings wired for electric lighting, *whether current be used in the building or not.* In other words, owners of buildings are fined for preparing to use the current at some future time. Electric lighting has had to contend with many difficulties and has passed through more than one crisis, and we have no fear that it will suffer permanent injury in the present instance. But while inveighing so strongly against a maximum 220 volts, the Underwriters seem to have lost sight entirely of a service which has existed for years, and which in their blind antipathy to electric lighting seems to have been left entirely unmolested. We refer to the stock ticker and news quotation service, the circuits of which enter hundreds of buildings. These systems are operated at a potential of about 300 volts alternating, and when breakdowns occur two circuits are coupled and the potential run up as high even as 600 volts. The insulation of these lines has never been put forth as a model in its way; on the contrary, we have known instances where these circuits have been used as a convenient "ground." Is it any wonder, therefore, that we frequently hear of *mysterious* fires due to electric light wires? It would be interesting to know the number of buildings in which mysterious "electric light" fires have occurred which were also provided with stock tickers, and we commend this subject to the attention of the New York Fire Underwriters. If they propose to be severe, let them be severe with justice and discretion.

ELECTRIC TRANSPORTATION DEPARTMENT.

ELECTRIC LAUNCHES ON THE CANALS OF VENICE.

The success of the electric launches on the lagoons of the World's Fair at Chicago was so marked that the idea of trying the same boats on the lagoons and canals of Venice at once suggested itself. The result was that one of the launches which had been in service at Jackson Park from the early spring was shipped last September to Venice, her motor and batteries being removed from the hull for the Atlantic voyage. Arrived at destination, the various parts were all reassembled, and under the fitting name of "Venezia" the little craft made her first appearance in the waters so long monopolized by the song and oar of Adria's gondolier. It is needless to say that she created a sensation, for her quiet and graceful performance, so different from the noisy, fussy movements of the steam launch, gave immediate proof that in the electric boat the time-honored gondolier had at last met a rival against which no halo of poetry and romance would help it greatly. Our picture of the "Venezia" was made recently as she lay in the waters of the Grand Canal right opposite the Doge's Palace. Mr. R. N. Chamberlain, whose intelligent engineering supervision did so much to render the boats a success at the Fair, where they carried 800,000 passengers proceeded to Venice as soon as he could be spared from Chicago, and had the boat fixed up in good shape. She now has 68 cells in 4 groups, governed by a mechanical controller. In order to protect her hull against the weeds and action of the canal water, her hull has been sheathed with copper. The success of the boat is indubitable, but we understand that the fleet of which she is the prototype will all be longer, so as to afford greater passenger capacity. Visitors to the World's Fair will note that her deck housing is slightly changed, it being now made to conform to the general style of the quaint cabin-top seen on the gondolas, in Venice, but not very much in evidence on the gondolas used at Chicago.

The American Electric Launch "Venezia," on the Grand Canal, Venice.

THE MAGNETIC ELECTRIC RAILWAY—AN UNDERGROUND CLOSED CONDUIT SYSTEM.

The many objections offered to the overhead construction required for the present trolley system of electric street railways, have induced inventors to try to evolve some system of electric propulsion which would eliminate the objectionable features of the overhead wires, by using some kind of underground conduit, from which the current could be conveyed to the motors on the car. Many different systems have been tried with varying success and we have illustrated them in our columns from time to time. We now take pleasure in presenting to our readers for the first time, an illustrated description of the closed conduit system of the Magnetic Electric Railway Company, of Salem, Mass., which has been attracting a great deal of attention from electricians for the past few months,—a system in which the conduit laid along the street between the car rails is entirely dead, except at the moment when a car is directly over any one section. The two engravings shown herewith illustrate the method of construction, one showing a longitudinal and the other a transverse section, through the conduit.

The construction is extremely simple and consists of a series of brass pipes or tubes A A, about ⅜ of an inch thick, laid in the street, between the rails, only the upper surface of the pipe being exposed.

Each pipe is filled with a core of wood or other insulating material shown clearly in the sectional view, with a slot running lengthwise of the pipe about one inch wide and two inches deep. In this slot are two steel rods C C about one-fourth of an inch in diameter lying loosely and so connected to a flexible wire, D D, as to allow the rod free play up and down in the slot.

These flexible wires are connected through each end of the brass pipe, which is hermetically sealed, with the main line wire

F F or substitute for the trolley wire. This line wire is in a conduit with the feed wires buried in the ground, more easily seen in the sectional view, Fig. 1. The steel rods are thus connected with the main line. The pipes are about 10 feet in length and laid with intervening spaces of about six feet.

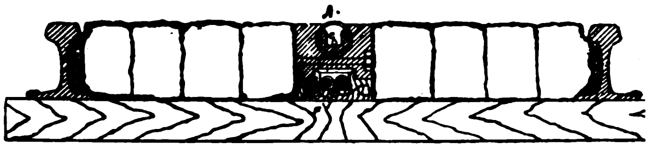

Fig. 1.—The Magnetic Electric Railway.—Transverse Section.

Underneath the car, which is equipped with the ordinary motors, are two magnets M M, Fig. 2, and two metal contact brushes E E, the brushes being placed close to the magnet and nearer the ends of the car. When the magnet under the car comes over the brass pipes, the rods in the pipe are instantly drawn up to the inner surface of the pipe and the pipe is thus connected with and becomes a part of the main line. The current then passes through the contact brushes to the motor. The distances between the magnets and the intervals between the brass pipes are so arranged that before the rear magnet and brush have left the section the front magnet and brush are over the next section so that there is a continuous current through the motor. The moment the magnet has passed by any section of the pipe, the rods drop down to the bottom of the slot and the brass pipes become dead and harmless, so that no section of pipe is alive except when under the car. Injury to any one of the pipes or sections does not affect any other section, or delay the car.

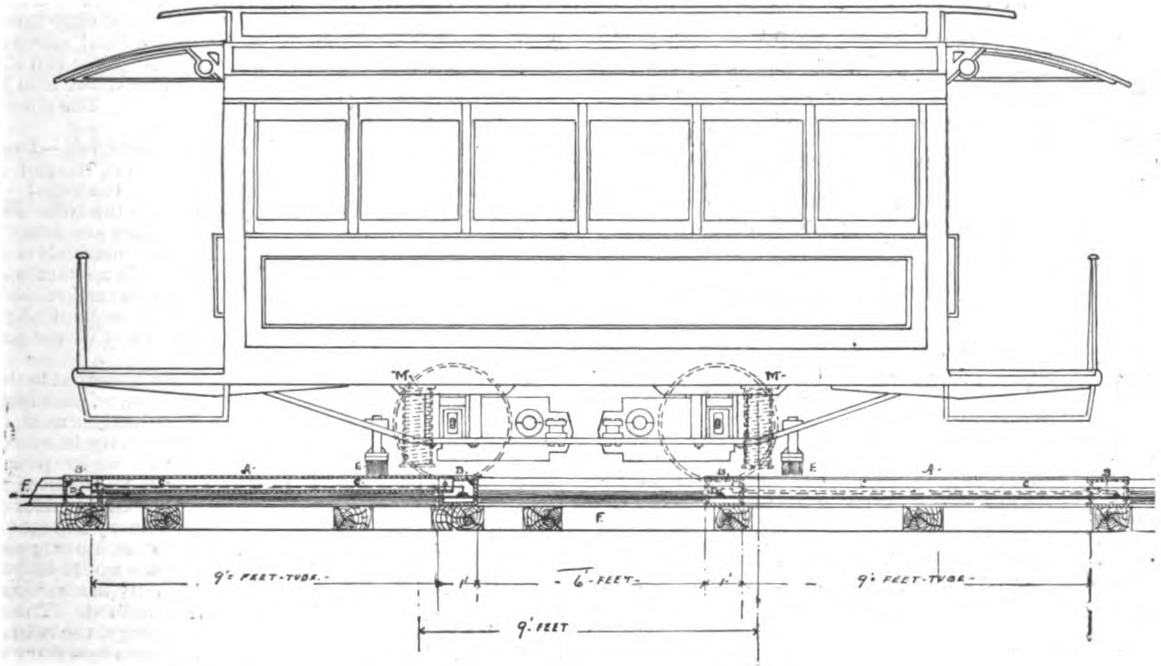

Fig. 2.—The Magnetic Electric Railway.—Longitudinal Section.

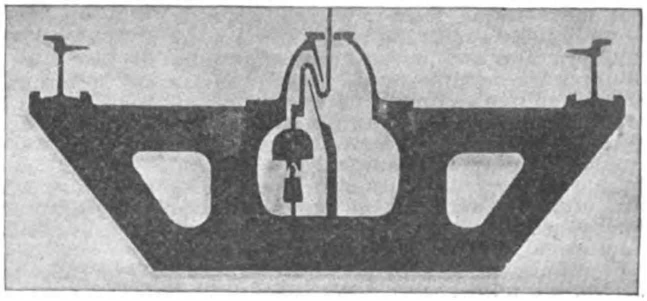
The experimental section at present laid down at Salem, although somewhat crude, has stood the test of all kinds of weather, and every electrical engineer who has seen it, has spoken in most marked terms of praise. There is no doubt that it does its work, and the car runs as smoothly and with as much certainty as if it depended upon its current from the conventional trolley. There can be no danger to horses by this system as no section of the pipe is alive, except the one immediately under a car. The brass pipe, which comes a little above the surface has been calculated to stand the hammering of the heaviest traffic and will last for years. The construction may be of the most substantial kind, the pipe being imbedded in cement, laid on top of the conduit containing the feeder wires, or between supporting steel flanges if preferred. No expensive foundation work is required, as is necessary where an open conduit is used, but the whole structure can be laid on top of the regular street railway cross ties.

The system is the invention of Mr. Edward H. Brown, of Salem, a young lawyer of that city, and the details have been worked out under the supervision of Mr. Mark Loud, the electrician of the company, and Mr. M. H. Ballou, consulting engineer for the company. Mr. Loud has spent much of his time in developing the electrical features of the system, and Mr. Ballou who is an electrical engineer of some 10 years' standing, has brought to the system much valuable experience in electric railway work, and has worked out the mechanical details for actual service construction. The company is a strong one, and is composed of the following officers and directors: L. G. Burnham, Boston, president; C. E. Hubbard, Boston, treasurer; Henry W. Peabody, Boston; F. Lincoln, New York; B. W. Russell, J. N. Peterson, A. F. Huntington, Charles Sanders, J. H. Poor and Edward H. Brown, directors.

THE GRIFFIN ELECTRIC RAILWAY CONDUIT.

Among the railway conduit systems recently brought forward that known as the Griffin system appears to be well worthy of consideration and study. By reference to the accompanying engraving it will be seen that the prominent feature of this system consists in the entire separation of the electrical from the drainage system. Beginning with the mechanical construction, it will be noted that the system embodies a slot in the roadbed and employs yokes, similar to those used in cable systems; but with this difference, namely, that the yokes are so small that they are sufficiently strong and rigid to act as the foundation of the complete structure without bracing. The conduit yokes are only 20 inches deep and 18 inches wide on the inside, which is ample for drainage, and they evidently occupy much less space than the cable conduit. The total depth of yoke, 26 inches brings it above the level of gas and water main so that the cost of laying is correspondingly diminished.



The Griffin Conduit Railway System.

The device for insuring that all surface water be kept out of the section where the wires and insulators are fixed will be seen to consist of an apron overhanging the electrical section of the conduit and running its whole length. A double curved arm bearing the trolley or contact device is connected to the car and presents no structural difficulties whatever. Manholes and hand holes placed at suitable intervals allow of ready inspection and repair.

While the apron insures dryness of the electrical section of the conduit and thus would, of itself, secure high insulation of the conductor even with the usual forms of insulators, additional insulation could be secured in the Griffin conduit by introducing an oil insulator which, it is estimated would give an insulation resistance of 10 megohms per mile with insulators only 25 feet apart. The leakage would therefore be practically reduced to nothing and with it also the deterioration of the structure from electrolytic action.

The trolley wheel and its insulated protector is so arranged that it is impossible for it to jump from the conductor and thus prevents the production of arcs which would soon wear out the contact device. The conductors being placed below the surface of the earth and not in contact with any overhead conductors, it goes without saying that immunity from lightning is insured.

A model of the Griffin system can be seen at the offices of the Electrical Conduit Traction Equipment Company, in this city, who are exploiting the system.

ELECTRIC CANAL BOAT PROPULSION WITH SPECIAL REFERENCE TO THE ERIE CANAL.[1]

BY JOSEPH SACHS.

ELECTRICITY has been suggested at various times as a source of energy for the propulsion of canal boats, but has never been brought to any such degree of prominence as within the last two or three years. The method as generally proposed and which was tried on the Erie Canal near Rochester during the latter part of 1893 consists in placing an electric motor upon the canal boat which revolves a screw propeller at the stern. This electric motor receives its current from suitable overhead wires through a flexible contact arrangement. There certainly is no doubt in regard to the successful mechanical operation of such a combination, but this method is not the only, and certainly not the most feasible and economical plan of operating canal boats.

There are in fact five other methods (six with propeller) of propelling boats in shallow and narrow bodies of water. They may be divided as follows:

1. Propellers. 2. Flexible submerged cable towing system (similar to European methods). 3. Rigid rail towing or hauling (exterior). 4. Rigid rail towing or hauling (submerged). 5. Movable cable. 6. Motor locomotive haulage.

The requirements for the successful system may be enumerated as follows: It is particularly necessary to deepen the Erie canal, as with the present depth of hardly 7 ft. the present maximum speed of 2½ miles per hour can hardly be maintained. Inasmuch as the successful method must attain at least 3 miles per hour, if not more, the canal must first be deepened. The method of propulsion must not injure the canal structure. It should appeal to the boatman as a better and cheaper method. The chance of breakdown of propelling machinery should be reduced to a minimum. It should enable the present methods of propulsion to be continued. Any structure erected should be strong and not easily disabled. The system should require as little machinery as possible upon the canal boat. The source of current supply should be constant.

Class I, Propeller.—Although this method would include all boat propellers such as paddle wheel, jet or screw, it has been found that the screw is the most feasible.

There are three methods of applying the screw to canal boat propulsion. 1. By placing the motor and screw directly upon the canal boat. 2. By the use of separate propelling tugs that carry no freight. 3. By the use of a false or detachable stern which holds the motor and screw. With any of the above methods it is necessary to have some source of current supply. The most generally proposed and practical method consists in suspending a wire or wires over the canal. As the canal cannot be used as a return circuit two wires are necessary for boats going in each direction (four wires for both). Arrangements must also be made to permit the boat to move laterally and therefore some form of flexible trolley carriage must be used. The most feasible plan of applying the screw will be some form of separate tug or false stern as by such arrangement various objections to placing the motor directly on the boat are obviated. Such methods will also be somewhat more efficient.

Objections to any propeller methods are: 1. Low efficiency of screw propulsion, and large operating expense. 2. Equipment of boats with motors. 3. Injury to structure by wash.

The effective energy to move a certain boat at a certain speed through a body of water is the same, no matter how the boat is propelled. The method of accomplishing this with the least loss above the effective power necessary is certainly the most efficient. In some sort of direct pulling or hauling system this loss will certainly be less than with the screw.

Class No. 2.—Submerged Cable.—The method consists in laying at the bottom of the canal a chain or cable which is raised and passed over rollers or friction drums on the propelling or towing boat which firmly grasp the cable or chain and by rotating pull the boat along the canal. This system is extensively used in Europe. A separate towing boat is used with suitable engine and boiler and the machinery necessary to pull on the cable or chain. In 1875 such a system was tried on the Erie but found to be unsuccessful. The electric motor can readily be substituted for the engine and boiler in such systems and current can be supplied, in a similar fashion to that used in the previous method. Instead of using two wires, one would only be necessary for each direction as the cable could be used as the return. As the motor takes up much less room than the engine and boiler a separate towing boat would perhaps not be necessary as in the European systems, but the motor and machinery could either be placed directly on the boat or upon a detachable platform as suggested by a German engineer. Such methods would not be successful on the Erie. Suffice it to say that it has been tried and found wanting. The principal objections are the slipping of the chain or cable, the large amount of slack chain each boat must take up and the necessity of dropping and taking up the cable a great number of times caused by the many locks on the Erie.

Class 3, Pulling on Rigid Rail (Exterior).—This method consists of a rigid rail or rack adjacent to the canal and parallel thereto. A motor is placed on the boat and rotates suitable rollers or pinions which engage the rail or rack and extend from the boat upon arms. The current is furnished by similar means to those in the previous cable methods but the lateral movement of the boat is obviated. The structure supporting the rail also supports the wire. Such a method is quite practical but also has some of the objections of the former cable method. The efficiency of the two are very nearly alike.

Class 4, Pulling of Rigid Rail (Submerged).—This method is the reverse of the above. Instead of placing the rail adjacent to the waterway it is laid at the bottom of the canal. A motor is placed on the propelling boat and rotates the roller engaging the rail or rack. The shaft to which the rollers are attached extends through the bottom of the boat. In such methods it is necessary to have a separate propelling boat. A single contact wire arrangement can be used as in either of the previous rail or cable methods. Such a method would no doubt operate mechanically but would be very costly and no more efficient than any of the previous pulling methods.

Class 5, Moving Cable.—This method is similar to the operation of an ordinary cable road with the difference, that instead of the cable pulling cars it is connected with the canal boats. The general plan would be to generate electricity in one or two very large central generating stations where water power could be procured and distributed at high pressure to electric cable operating stations located along the route of the canal. Here large electric motors would operate the cable machinery and move the cable. An arm would extend from the boat to the moving cable and by use of suitable gripping devices the boats would be pulled along. The boat would actually be moved wholly mechanically but the system as a whole would be an electric method. The various losses in the many transformations of energy, the operation of the long cable, the many cable power plants necessary and the extremely large cost and complicated mechanism would appear to make this method somewhat impractical.

Class 6, Motor Locomotive Haulage.—This method is really an elaboration of the old and primitive mule method, but instead of the slow and uneconomical animal a more rapid, efficient, electromechanical mule is substituted. It consists in running an electric motor parallel to the canal upon a suitable structure or track and receiving current from contact wires adjacent thereto. This motor locomotive is connected with the boat by suitable means and hauls the same by being propelled along the track or structure. Such electric locomotives may be large and heavy and be controlled by a motorman directly thereon and haul a train of boats necessitating a large, heavy and strong structure of track; or they may be small and run upon a light structure, each motor being attached to a single boat and the motor on the structure regulated from the boat. The first method would necessitate the location of tracks on each side of the canal and would interfere with the present methods and be very costly and perhaps somewhat impractical.

The author believed in the latter method will be found a solution of the electric canal boat propulsion problem. A light, strong structure can be erected along the canal in such manner as not to interfere with the present methods. Upon this support, small electric motors are adapted to be propelled in either direction by a current received from wires supported on the structure. The boat in the canal is connected with the motor by a tow line and the motor is started, stopped and regulated from the boat.

Although the boats may be coupled each boat is pulled by a separate motor thereby permitting the erection of a light, small structure only strong enough to stand the strain of one boat. All the motors are regulated from one source on the first boat. Devices are arranged for switching and passing of the boats and special arrangements for furnishing current and gripping the rail are used. The motors for both directions may be operated on one or both banks of the canal or suspended overhead.

---

[1] Abstract of a lecture delivered before the New York Electrical Society, Feb. 15, 1894.

The main features of such a method are: 1. The boats are not changed. 2. Any other method may also be used. 3. Economy of operation. 4. No damage to canal structure. 5. No machinery on boat. 6. Chance of being stalled reduced to a minimum.

The method of haulage last described is certainly very feasible, and perhaps the most practical of the various haulage systems described. As compared with a screw propeller method it is very much more efficient and has none of its disadvantages. A saving of over 15 per cent. can be shown over the operation of the propeller method. This is taking into consideration the cost of plant, interest, coal, maintenance, labor etc.

To operate 600 boats constantly moving on the Erie Canal (300 going each way) at three miles per hour in 8 ft. of water and allowing a constant operation at this rate for 220 days the trolley propeller plant would cost $4,500,000, and operating expenses would amount to about $800,000 for that period.

To operate the same number of boats by the hauling method the first cost of plant would be $5,550,000 and cost of operation about $680,000.

If the electric propelling system is installed and maintained by the State and we do not consider interest on plant, a much greater saving can be shown, in favor of the hauling method. With a properly installed plant, on this basis, from 30–50 per cent. can be saved over the present steam method.

It will be seen that although the first cost is greater in the latter method the operation of boats per boat-mile would be less. Aside from this fact however, the latter method has so many advantages over the propeller that some form thereof will no doubt be the future method of operating canal boats.

MISCELLANEOUS.

ESSENTIAL STATION INSTRUMENTS.[1]

BY PROF. D. C. JACKSON.

The term, station instruments, may be made to cover a variety of tools and indicating devices from the coal shovel to the main fuse block.

A great many of the fires in electric stations start at the switchboard. This can be made almost absolutely safe, and with proper construction switchboard fires should be almost unknown. Build your switchboards of non combustible material. Marble is not very expensive, and is better than slate. If combustible material is used for the board, never make it solid, but arrange it simply as a skeleton upon which the instruments may be secured. Set the switchboard at least two feet (three feet is better) from the wall, and have all the wiring done in the best possible manner and in plain sight. Under no circumstances close the ends of the space back of the board, making it into a sort of rubbish closet.

The switchboard should be located conveniently, and the instruments conveniently placed thereon. The dynamo instruments should be bunched together, and the different devices belonging to each individual dynamo circuit should be placed in vertical rows. Pressure indicators, cutting-in galvanometers, ground detectors, and other instruments which are common to all the dynamos should be placed where they are easily seen by a man at the dynamo regulators. Devices placed in the feeder circuits may be placed either above or at one side of the dynamo instruments. In any case the arrangement should be such that extensions may be easily made.

The number of instruments on the dynamo and feeder circuits should never be multiplied unnecessarily. Their type and number in any case depends upon the type of the apparatus and the purpose for which they are used. If arc light dynamos with separate regulators or controllers are used, these should be solidly mounted near the dynamos to which they belong. In each case the maximum of safety and convenience should be sought in the arrangement of the instruments. The arrangement of the standard panel switchboards of two or three prominent manufacturing companies may be followed with profit. Where two or more classes of machinery are used. the different types of dynamos should be set together, and the switchboards should be distinct, but side by side.

Let us drop the electrical question now and go over to the steam side. The first instrument on this list is a platform scale for weighing in the coal. Daily records of coal consumed should be carefully kept and compared with records of the electrical output day by day, week by week and month by month.

The coal shovel is a very essential instrument which requires a great deal of careful supervision. The coal records and automatic records of steam pressure serve this purpose. An automatic steam pressure recorder is not an expensive instrument. If one is properly installed and its indications are acted upon by the manager, it will soon save its cost. Thermometers in the feed water pipe and in the steam pipe are not essential to the operation of a station, but they are certainly advantageous. A throttling calorimeter made up of ordinary fittings is also serviceable. They are not kid-glove affairs, but good common sense appliances. Steam gauges on the boilers are essential, but it is not usual to put one in the steam-pipe near the engine. It is a good idea, however. Five to ten per cent. of the fuel used on day load makes a considerable item in the period of a year, which will pay for the recording boiler gauge and a gauge in the engine pipe, besides adding a sum to the dividend account. It is true that the gauge in the engine pipe does not remove the fireman's impulse to reduce pressure by throttling, but if his work is constantly under inspection, the impulse is much less likely to be irresistible. In this connection, let me remark regarding the usual practice of cutting off the condenser at times of light load when condensing engines are used. Under such circumstances, fuel is saved by keeping the condenser running, but reducing the boiler pressure to hold the engine cut off at an economical point.

Another instrument of much use is the engine indicator. This is particularly useful in determining whether the engines are working at their most economical cut-off and whether the valves are properly set. If cards are taken at fixed intervals and filed for reference, they may be made a decided aid in the effort to keep everything at the most economical point.

I have spoken particularly of instruments that are frequently not used in the stations, but which can be made of much valuable assistance in reducing expenses. These are not varnished theoretical ideas, but hard common sense dividend earning suggestions. They can be put into service without increasing the operating costs in any way, and the instruments will ordinarily quickly pay for themselves.

THE LATEST THINGS IN ELECTRICITY.[2]

The author first drew attention to the difference in the conditions existing now and ten years ago in the prices of materials and the gullibility of central station managers. He next referred to a new wire the insulation of which consists of cotton just as it comes from the gin saturated with a high grade of insulating compound. Regarding transformers, he spoke of the newer types embodying the designs which obviated the necessity of oil insulation and had the fuse-wires accessibe for renewal in case of a blow out. Great progress had also been made in high candle power incandescent lamps; lamps of 500 and 1,000 c. p. now being available burning at from 2½ to 2¾ watts per c. p. Reference was also made to the improved alternating arc lamps and to Mr. Tesla's work in high frequency lighting.

THE ACTION OF ELECTROMAGNETIC RADIATION ON FILMS CONTAINING METALLIC POWDERS.[3]

After noticing the resemblance of the phenomena exhibited by tubes containing metallic filings shown by Mr. Croft on October 27th, to those of photoelectric impulsion cells, he described films of gelatine and collodion containing metallic powders. Directions for preparing the films are given in the paper. On inserting such a film in circuit with a battery, key and galvanometer it acts as an insulator. To render a small portion conducting, the electrodes on the surface of the film are brought very close together, and one of the wires touched with an electrified body. (An electric gas lighter was often used.) This caused a current to pass. The electrodes may then be separated a little further and the process repeated until any desired portion is rendered conducting. The peculiarity of such a film is that, if the circuit be broken at the film, the film becomes an insulator, whereas breaking the circuit at any other point leaves the film conducting.

A short discussion followed, and Prof. Minchin, in his reply, maintained that the phenomena were due to electric impulses.

THE ELECTRICAL PRODUCTION OF PARA-AMIDO-PHENOL SULPHONIC ACID.

Hitherto para-amido-phenol which is used in photography and in the manufacture of dye-stuffs has commonly been prepared by the action or reducing agents on para-nitro-phenol. Recently, however, Messrs. A. A. Noyes and A. A. Clement, of Boston, have discovered that para-amido-phenol-sulphonic acid can be made by electrolyzing a sulphuric acid solution of nitrobenzol and have secured a patent upon their process.

One part by weight of nitro-benzol is dissolved in four parts of concentrated sulphuric acid, and this solution is submitted to electrolysis. Platinum is used for the positive electrode and cast iron for the negative electrode. The positive electrode is placed within a porous cup nearly filled with concentrated sulphuric acid and this cup and the negative electrode are placed in the vessel containing the sulphuric acid solution of the nitro-benzol, the purpose of the porous cup being to protect the reduction products of the nitro-benzol from the action of the oxygen set free at the positive electrode. An electric current of such strength is passed through the solution that its temperature is maintained at 90° to 100° centigrade without application of external heat, and the action of the current is continued until a portion of the solution no longer precipitates an oil (unchanged nitro-benzol) on dilution with water. After the electrolysis is completed, water is added to the product and the liquid is filtered. The solid collected on the filter is washed with water and treated with a solution of caustic soda or other alkali, by which operation the para-amido-phenol-sulphonic acid is dissolved out as a sodium salt. The sulphonic acid itself is precipitated from this solution by neutralizing with hydrochloric acid; it is then washed with water, and dried; or, if desired, it can be further purified by dissolving it again in alkali and reprecipitating it with acid.

AFRICAN TELEGRAPH LINES.[1]

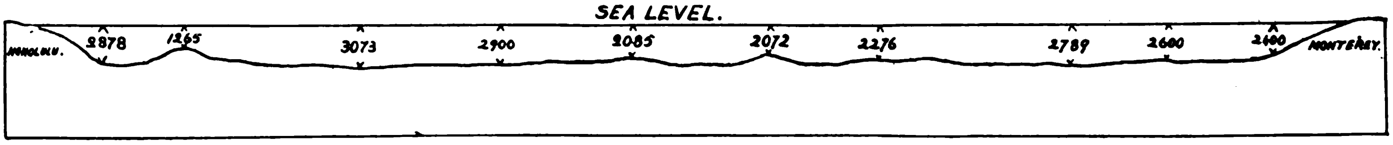
THE Congo State has decided to construct a telegraph line, fifteen hundred miles up the Congo River to Kasongo, and then two hundred and fifty miles east to Lake Tanganyika. The line is now building at its western end, along the track of the Congo Railroad. Perhaps ten years will elapse before the telegraph station is built on the borders of the lake. By that time the Germans and the British will have carried out their plan to join the east coast by wire with Tanganyika and Victoria Nyanza.

There is nothing visionary, to-day, about such schemes as these. Twelve years ago Stanley's idea of a telegraph line to Uganda was condemned as chimerical, but to-day a hard-headed capitalist like Cecil Rhodes pins his faith to the practicability of an inland telegraph line from South Africa to Cairo. The wire already stretches from Cape Town four-fifths of the way to the Zambesi. From the delta of that river messages are flashed more than half the way to Lake Nyassa. No obstacle has yet appeared that cannot be overcome.

The development of the telegraph service in Africa will come gradually, and it will be of immense advantage to the various enterprises there. Egypt, among the civilized lands, bids fair to profit most; for the day is surely coming when she will be notified many weeks in advance of the amount of the Nile floods that are on the way, and these statistics and warnings will be of the greatest practical value to the densely populated lower valley of the Nile.

THE BED OF THE PROPOSED PACIFIC CABLE.

THE *Hawaiian Gazette* recently published an interesting article on the proposed cable between the United States and Hawaii, giving a résumé of the work that has been done in this direction, and a profile, which we reproduce, of the last survey made. This route, considered by far the most suitable for the purpose, was surveyed by the U. S. S. Albatross, and extends from Diamond Head, Honolulu, to Salinas on the shore of Monterey Bay, California.



PROFILE OF THE BED OF THE PROPOSED PACIFIC CABLE.

There a submarine valley has been discovered, commencing at the mouth of what was formerly the Salinas river, and running westerly at the bottom of the sea, for a few miles, furnishing a most remarkable artificial bed for laying a cable. The entire absence of rocks, and the presence of deep soft mud and sand throughout this valley seems to have prepared it for this special service of a telegraph cable. The interesting report made by Lieut. Clover of the Albatross, who had command of this last expedition, shows that for the entire distance from the California shore to the terminus near Diamond Head, the ocean's bed on this route is destitute of rocks of any kind, while the bed for the most part consists of soft ooze and mud into which a cable will sink probably several feet and be entirely submerged and protected against marine insects and any obstacles which might tend to harm it if lying on the surface of the ocean floor.

Lieut. Clover's report says that this survey "was prosecuted with all the care and accuracy that the means for modern deep sea research afford, and it is believed that the maps and observations present a good knowledge of the route and establish the fact that the laying of a cable on almost any line between California and the Hawaiian Islands is practicable. A lane about 300 miles wide was developed between California and Hawaii, and the results seems to indicate the most favorable route to be a rhumb line between Monterey Bay, Cal., and Honolulu. This route has been determined upon as the most practicable, since it is the one that will require a minimum length of cable in passing over an even bottom consisting of soil which is favorable for its protection and preservation, avoiding submarine mountains and volcanic regions where substances exercising an injurious chemical action on the covering of the cable are likely to exist and where future convulsions may cause its destruction."

The distance from Hawaii to Vancouver, including the slack, is 2675 miles; from Hawaii to San Francisco, including the slack, it is 2247 miles. This latter route is therefore shorter by 428 miles and as the cable, when laid, is estimated to cost $1200 a mile, the latter route can be laid for $510,000 less than the Vancouver route. On the same estimate, the cost of laying a cable from Hawaii to Monterey Bay will be $2,696,400.

THE TREND OF ELECTRICAL INVESTMENT.[1]

BY H. C. THOM.

Eighty per cent. of the people who grumble at the monthly bill have been given service at such a rate as to entail a loss upon the company they patronize. How long can this continue? Men who have kept steady in faith for years will falter by and by. Stock will be sold for what it will bring and the weary burden laid down. Electrical development must suffer if holders of stock are too often pinched.

Electricity is a quick friend, an obedient servant and an insidious power for good or evil. Good if well managed; evil if guided by ignorance. If generated for less than seventeen per cent. net profit (10 per cent. for depreciation, and 7 per cent. on the investment), it will ruin homes and devastate the fertile field of research and progress. Electrical investigation has called out the highest talent known to the mechanical and inventive world. Let this talent be seconded by the same type of business sagacity, and progress will be unrestricted and the confidence of capital will be restored. The public is willing to pay living rates. At the same time corporations have no moral right to so conduct business that the effect of ignorance and mismanagement falls upon our necessary friend the customer. I most earnestly trust that this paper will start a movement which looks toward the establishment of rates that will be just to the public and remunerative to corporations; that will strengthen the heart of the student; encourage research and secure the eternal friendship of the capitalist.

HOUSTON & KENNELLY.

It will doubtless surprise many of our readers to learn that two gentlemen well known in the electrical field have determined to sever the connections they have held so long in their respective vocations. We allude to Edwin J. Houston, Professor of Physical Geography and Natural Philosophy in the Central High School of Philadelphia, who has held this chair for the past twenty-six years and who has just resigned; and to Mr. A. E. Kennelly, who during the past six years has been Mr. Edison's right hand man and chief electrician and who is about to leave the Edison laboratory.

We are glad to inform our readers that these gentlemen have decided to establish in Philadelphia a firm of electrical experts to be known as Houston & Kennelly. It is not necessary to remind our readers that Prof. Houston is President and Mr. Kennelly one of the Vice-Presidents of the American Institute of Electrical Engineers, in whose work they have taken the liveliest interest.

THE BOYNTON BICYCLE ROAD.—Messrs. Gillies and McEchen, of Sydney, Nova Scotia, solicitors for the applicants, announce that they will apply to the Canadian Parliament for an act to incorporate a company under the name of the Boynton Bicycle Electric Railway Co., of Canada, to construct and operate a bicycle electric railway from the City of Winnipeg, Manitoba, to the Port of Louisbourg in the County of Cape Breton, Nova Scotia, and between any places within said points, with power to acquire, take and use water powers and to make contracts for supplying power to the said railway, also to construct and operate all works for said railway.

1. Abstract of a paper read before the Northwestern Electrical Association, January 18, 1894.

LETTERS TO THE EDITOR.

A SERVICE OF GOOD WILL FOR THE ELECTRICAL FRATERNITY.

KINDLY inform your readers that I will be very glad to oblige any one of them in such ways as may be by them desired, to make their attendance at the Convention of the National Electric Light Association, to be held in this city February 27th and 28th and March 1st, enjoyable. It may be especially serviceable to some to have arrangements made for hotel accommodations, for printing cards, circulars, etc., before their arrival. If so, I shall be glad to attend to these and similar matters for them, as an expression of my good faith. I should be addressed as follows:

ALLEN R. FOOTE,

Care the National Statistical Association, Washington Loan & Trust Company Building, Washington, D. C.

CHLORIDE ACCUMULATOR LITIGATION.

THE CONSOLIDATED ELECTRIC STORAGE COMPANY, controlling the Brush patents, knowing that in the "Chloride" accumulator manufactured by The Electric Storage Battery Company the defects heretofore developed in the various types of battery constructed on the principles covered by the Brush patents have been practically overcome, have finally found themselves in the position where they must either abandon the storage battery field, or claim that the Chloride system of storage did in some way infringe the Brush patents.

Not being able by a systematic circulation of such statements to deter purchasers of storage batteries from taking the Chloride battery in preference to the inferior batteries made by the Consolidated company and their licensees, they have finally instituted suit, the only object of which, we believe, is to frighten intending purchasers of batteries who are not familiar with the subject, by the idea that there may be some foundation for their claim of infringement, and thus delay as long as possible the time when the Chloride battery will be the only battery that purchasers requiring a satisfactory system of storage will accept.

Without intrenching upon the province of the court, or venturing to forecast its judgment, we are advised by the best of counsel, and the most eminent scientific experts in this country, after a most thorough examination of the state of the art, that we do not infringe the Brush or any other patents in the slightest degree. Among these experts are Professor Charles F. Chandler of Columbia College, New York; Professor George F. Barker of the University of Pennsylvania, and others, copies of whose opinions we will be glad to furnish to any who may be interested in reading them. We quote briefly from a joint report of Professors Chandler and Barker, as follows:

NEW YORK, December 6th, 1893.

W. W. GIBBS, ESQ.,
President Electric Storage Battery Co., Philadelphia, Pa.

DEAR SIR:—In reply to your inquiries as to whether your Chloride Accumulator itself or the process by which it is manufactured or the way in which it is used in any way infringes the Brush Secondary Battery Patents or any of them, we beg to make the following report:

Having been engaged as experts in the litigation between the Brush Electric Company, the Julien Electric Company and the Electrical Accumulator Company, we are quite familiar with the Brush patents and with the interpretation which has been put upon them by the Judges of the United States Circuit Court and the Circuit Court of Appeals. * * *

You construct a composite plate consisting of tablets of chloride of lead and chloride of zinc in a frame of metal. There is no active material in this composite plate nor is there any material ready to become active in a seconday battery. Nor is there any material which is absorptive in a secondary battery.

In fact, as far as any use of this composite plate in a secondary battery is concerned it is practically inoperative and worthless. Before any use can be made of this composite plate it must be exposed to a process of electrical disintegration, not in the bath or fluid of a secondary battery, but in a totally different bath in connection with plates of zinc. And only after this electrical disintegration is the plate of any use in a secondary battery. * * *

Our understanding of the Brush claims is confirmed by the language of Judge Shipman, which reads as follows:

"The mechanical application of a layer of lead oxide to each of two lead plates, before the plates are placed in the battery fluid, these coatings being at once active material and ready for the charging current, when immersed in the battery fluid, was, in general terms, the distinguishing feature of the Brush invention. * * * * These claims describe and necessarily refer to a secondary battery as heretofore defined; a plate or support which is insoluble in the liquid, mechanically supports the active material and electrically conducts the current of electricity through it; the specified active or absorptive material being oxides of lead which are primarily mechanically applied to the plates and in such state of minute division as to be at once capable of being charged without previous process of 'formation' by electrical disintegration."

In conclusion we are therefore of the opinion that your battery does not either in itself, in the process by which it is manufactured, or in its use infringe the claims of the Brush patents.

We are familiar with all the batteries that have been held to infringe the Brush patents, and in all of them, the distinguishing features of the Brush invention as set forth in the above quoted passages of the opinion of the Court of Appeals were clearly present.

No battery such as yours, has been held to be an infringement of the Brush patent, and from our understanding of the opinion of the court of last resort, the Circuit Court of Appeals, such conclusion would seem to be impossible.

(Signed) C. F. CHANDLER, Ph. D.,
G. F. BARKER, M. D.

A careful reading of these complete reports, we believe, will promptly convince any one informed on the subject, that there is no ground for any claim of infringement, and that the only hope and expectation of the Consolidated company is to temporarily injure the business of The Electric Storage Battery Company, which they have been endeavoring to do for many months past, by the circulation of false letters and statements.

We, therefore, propose to continue making and selling our battery, and shall protect and save harmless all users of the Chloride Accumulator.

W. W. GIBBS,
President.

PHILADELPHIA, PA., Feb. 14, 1894.

THE HENRY SPEED RECORDER FOR ELECTRIC CARS.

I HAVE read your editorial on the subject of speed indicators for motor cars in the ENGINEER of Feb. 7, and as I am probably one of the few who have tested the advantages of such an attachment I wish to endorse your views.

The Railway Commissioners of the State of New York have recently recommended that all motor cars be provided with an automatic governing device to prevent excessive and reckless speeds. The necessity for both of these appliances occurred to me at an early day and they are subject matters of my patent No. 345,845 of July 1886. In the development of the electric railway motor it was thought necessary to strip it of all superfluous mechanism; in doing so quite a number of theoretically advantageous refinements were dropped. Now that the motor as built will stand any form of neglect or abuse may we not safely turn back and gradually apply the good but probably more delicate features that were left on the way side during a rapid march.

There is great need of a law that would compel all railroad companies to put speed recorders on locomotives and motor cars. Such an appliance, which is within reach, would soon separate the reckless from careful drivers. As it is at present, when an accident accident occurs, the liability is determined by guess work.

J. C. HENRY.

WESTFIELD, N. J.

INFLUENCE OF COLD ON PHOSPHORESCENT TUBES.

IN regard to the interesting experiments of Prof. Dewar reported in your issue of January 31, on page 83, is not the ceasing of the phenomenon of phosphorescence with the intense cold due to the *condensation* of the attenuated vapors previously in the glass tubes? This would make the vacuum more nearly perfect, and it is well known that the Geissler-tube effects are not found if the tubes are completely exhausted. This fact is taken advantage of in the testing of incandescent lamps for vacuum. It may be that Prof. Dewar considers that his question, "What does this mean?" was clearly answered by him, but it puzzled me, and I venture to send you this thought.

MORGAN BROOKS.

MINNEAPOLIS, MINN., Feb. 10, 1894.

COLLEGE NOTES.

ELECTRICITY AT THE YOUNG MEN'S INSTITUTE, NEW YORK.

We are pleased to learn that the class in Electrical Engineering at the Young Men's Institute, Nos. 222 & 224 Bowery, is being largely attended this winter and that the interest of the young men in their work is steadily increasing. The Managers of the Institute are very progressive and over a year ago they started this course of instruction in connection with their other educational classes. Last winter the class was well attended, and this year its membership has increased, and the Managers of the Institute are well pleased with the amount and especially with the character of the work now being done.

The class is made up of men from electrical construction and manufacturing companies; engineers from central stations and isolated lighting plants; and also men from street railway and electric power stations. As would be expected this class of practical men is eager for practical instruction and the Institute has secured as instructor, Mr. R. H. Mansfield, Jr., who is connected with one of the largest electrical engineering companies of this city and is actively engaged in practical engineering work. In this year's course up to the present the fundamental principles of electricity and magnetism have been carefully explained and the application of these principles in the telegraph, telephone, dynamo electric machine, electrical transmission of energy and its transformation into light, heat and mechanical power, are now being discussed.

COLUMBIA COLLEGE UNIVERSITY EXTENSION LECTURES.

On Feb. 14, Prof. F. B. Croker delivered a lecture on "Electric Lighting" in the University Extension Course which was attended by a numerous audience. The lecture was accompanied by experiments on arc and incandescent lighting.

The lecture of Mr. Nikola Tesla on Electric Power, announced for Feb. 26, has been postponed. Due notice will be given of its delivery. No lecture in the course will be advanced to take its place.

LITERATURE.

Rules for Electricity-Works Management. By Albert Gay. London: 1894. Published by LIGHTNING. Pocket size.

This is a series of instructions intended for the government of those in charge of the various departments of an electric light station, and of the outside work connected therewith. The rules cover the following: Electricians in charge; meter inspectors; jointers and jointers' assistants; meter room attendants; wiring inspectors; electricians on mains; engine drivers; stokers, and cleaners. Although designed more particularly for incandescent lighting stations, both continuous and alternating, many of the rules are equally applicable to arc station work. The rules evidently represent the result of considerable experience in the management of station employees and with slight modifications could be applied with benefit to many stations in this country. The instructions for each department are printed as a separate folder on linen backed paper so that they can be carried about constantly in the pocket.

Un Metodo per la Trattazione dei Vettori Rotanti od Alternativi ed una Applicazione di esso ai Motori Elettrici a Correnti Alternate. (A Method for the Treatment of Rotating or Alternating Vectors and an Application of the same to Alternate Current Motors.) Memoir by Prof. Galileo Ferraris. Reprinted from the Proceedings of the Royal Academy of Sciences of Turin. Turin, 1893. Vincenzo Bona. 24 pp. quarto.

REPORTS OF COMPANIES.

EMBARRASSMENT OF THE WADDELL-ENTZ COMPANY.

ON Feb. 14 Mr. Montgomery Waddell was appointed temporary receiver of the Waddell-Entz Company of Bridgeport, Conn., by Judge George W. Wheeler of the Superior Court. There has been given by the Waddell-Entz Company to R. Knauth, trustee, of New York, a chattel mortgage for $150,000 on the machinery, stock and movables in Bridgeport and New York. Mr. Knauth, as trustee, represents the following: Knauth, Nachod & Kuehne, Charles L. Colby, and Edwin Brown, subscribers for $10,000 worth of stock; C. E. Knoblouch, Thomas L. James, John Stratton, Henry F. Spencer, John C. Brown, Eugene Colby, Rowland G. Hazard, and Charles L. Brace, subscribers for from $2,500 to $5,000 of stock.

The inventory includes all the rolling stock, motors, and other property in the station of the company at One Hundred and Twenty-seventh street and Second avenue, New York City. The company is organized under the laws of the State of New Jersey. Its capital is $5,000,000. Mr. Waddell says that the inability to collect outstanding obligations due the company is the chief cause of the appointment of a receiver. The company hope to get straightened out very shortly.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE 84th meeting of the Institute will be held at Headquarters, 12 West Thirty-first street, New York City, on Wednesday, February 21, at 8 o'clock p. m.

The report of the Committee on Revision of the Rule Governing Elections, will be taken up for consideration. The rule as it would appear if amended as proposed by the committee, is printed on page lii of the January issue of the *Transactions*, and also in the February issue.

The following paper will be presented by Mr. H. Ward Leonard, of New York City: "How Shall We Operate an Electric Railway Extending 100 Miles from the Power Station." A proposed arrangement of apparatus for this purpose will be shown in operation at the meeting.

Also the following paper by Philip Mauro, Esq., of Washington, D. C.: "Concerning a Change of Policy in the Administration of the Patent Office."

MR. CHARLES RETTIE, E. E., 18 Geraint street, Liverpool, sends us a very striking calendar in colors that he has issued. It has several vignettes illustrative of electrical work, including one that shows the electrical ocean-going vessel of the future.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEBRUARY 6, 1894

Accumulators:—

Secondary Battery, H. H. Carpenter, St. Louis, Mo., 514,260. Filed Dec. 21, 1892

Has for its object to increase the area of active material without increasing the weight, bulk or cost of the cell.

Electrode for Secondary Batteries, J. Legay and L. Legay, Fils, of Levallois, France, 514.267. Filed Oct. 13, 1890.

Claim 1 follows:

An electrode for batteries composed of spirally twisted wires twisted together in the form of a cable.

Alarms and Signals:—

Circuit Controller, E. J. McEvoy, New York, 514,019. Filed Aug. 31, 1893.

A circuit controller actuated by the opening of a door or window.

Device for Preventing Railway Collisions, G. F. Klaffsy and F. Faltinowsky, New York, 514,083. Filed Nov. 3, 1893

An electric block signal system for steam railways which shall automatically check the movement of the train upon entering an occupied block.

Signaling System, J. G. Noyes and L. Winterhalder, Milford, Conn., 514,128. Filed July 3, 1893.

A signal system in which the "want" and the locality are sent over separate circuits and received and recorded at a central station.

Electric Alarm, F. Sauer and C. Hentzschel, Berlin, Germany, 514,202. Filed July 8, 1893.

An electric alarm for doors in which the circuit is completed upon the withdrawing of the lock or bolt.

Electric Signaling Device, J. N. Connolly, New York, 514,212. Filed Nov. 9, 1893.

Relates to means for mounting the bell and making connections with the circuit.

Auxiliary Fire-Alarm Telegraph, J. Sachs, New York, 514,279. Filed Apl. 20, 1893.

Relates to fire alarms in which a signal is sent upon a main circuit leading to a central office by means of auxiliary circuits leading to a number of local auxiliary boxes, so that by the operation of one of the latter an alarm is transmitted on the main circuit in the same manner as if it had been directly transmitted from the main alarm mechanism.

Signaling Apparatus, E. R. Wilder, New York, 514,297. Filed May 1, 1893.

Claim 1 follows:

A signal tape having the signals embossed therein in combination with a circuit closer moved by contact with the embossed surface and a bolster to hold up the embossed portion while acting on the circuit closer.

Automatic Electric Fire Alarm, W. A. Guthrie, Durham, N. C., 514,361. Filed Aug. 19, 1893.

A thermostatic fire alarm in which the circuit is completed by the fusing of an alloy.

Fire Alarm and Sprinkler, W. A. Guthrie, Durham, N. C., 514,362. Filed Oct. 17, 1893.

Electric Signaling Apparatus for Railways, E. C. Wiley, Bristol, Tenn., 514,398. Filed May 11, 1893.

An automatic electric block signal system.

Conductors, Conduits and Insulators:—

Electric Conductor, H. F. Chick, Watertown, Mass., 513,982. Filed May 1, 1893.

Employs a braided covering outside of which is a braided wire protecting jacket.

Electrical Conductor, N. Tesla, New York, 514,167. Filed Jan. 2, 1892.

Has for its object to prevent interference by induction on line conductors carrying high potential alternating currents, and provides between the sheath of the conductor and the ground a path of very high ohmic resistance. (See THE ELECTRICAL ENGINEER, Feb. 14.)

Insulator, L. B. Gray, Boston, Mass., 514,221. Filed June 22, 1893.

Employs a supplementary insulator surrounding the peg and held against the cross bar by screwing the insulator proper down upon it.

Distribution:—

Load-Governor for Electric Currents, F. E. Pritchard, Oswego, N. Y. 514,030. Filed Nov. 19, 1891.

Employs a resistance coil connected to one conductor and a movable contact arm connected to the other, and a governor for forcing the movable arm into contact with the resistance.

Electrical Transmission of Power, R. M. Hunter, Philadelphia, Pa., 514,228. Filed Nov. 18, 1889.

Relates to the generating of currents of high potential for long distance transmission and transforming them to currents of lower potential at the points where they are required for service.

Dynamos and Motors:—

Dynamo and Motor, M. Waddell, Bridgeport, Conn., 514,047. Filed March 13, 1893.

Relates especially to the form of the brush carrier and its support.

Electric Motor, J. D. Ihlder, Yonkers, N. Y., 514,077. Filed Sept. 29, 1893.

An elevator motor having a shunt field magnet coil connected to the terminals of the supply circuit, a series field magnet coil included in the armature circuit and a resistance arranged in parallel with the series field magnet circuits.

Electric Elevator Motor, J. D. Ihlder, Yonkers, N. Y., 514,078. Filed Sept. 29, 1893.

Similar to No. 514,077.

Alternating Dynamo, J. J. Wood, Fort Wayne, Ind., 514.140. Filed June 20, 1893.

The invention relates to the mounting of the resistance in the field regulating shunt, in the construction of the commutator and brush yoke, and in means for retaining the exciting coil in place on the poles of the field magnet.

Commutator Brush, J. F. Kester, Buffalo, N. Y., 514,150. Filed Nov. 23, 1893.

A lubricator leaf for commutator brushes provided with interstices filled with a lubricating materal composed principally of beeswax.

Means for Generating Electric Currents, N. Tesla, New York, 514,168. Filed Aug. 2, 1893.

Provides means for compelling the discharge to take place through an insulating liquid and between terminal points brought together and separated periodically by the flow of the insulating liquid. (See THE ELECTRICAL ENGINEER Feb. 14.)

Magneto Electric Machine, A. J. Potter, New Hartford, N. Y., 514,241. Filed June 15, 1893.

Regulator for Electric Motors, S. H. Short, Cleveland, O., 514,429. Filed Jan. 26, 1891.

Employs two independent commutating switches for connecting the coils of different field magnets in multiple or in series, a rheostat included in the field circuits of both motors, a reversing switch in the field circuit of each motor and means for connecting the commutating switches and rheostat so that the parts may be operated simultaneously from either end of the car.

Galvanic and Thermo-Electric Batteries :—

Electric Battery, F. Bayer, New York, 514,115. Filed Aug. 24, 1893.

Employs an insulated supporting rod, an insulated cup containing mercury on the lower end of the rod and two sets of blocks of zinc strung upon the rod.

Lamps and Appurtenances :—

Hood for Electric Arc Lamps, S. Bergmann, New York, 514,057. Filed Jan. 10, 1893.

Electric Arc-Light Fixture, S. Bergmann, New York, 514,058. Filed Jan. 10, 1893.

Employs a removable holder for the lower carbon provided with an ash pan.

Electric Arc Lamp, G. G. Wagner, New York, 514,139. Filed November 15, 1892.

Employs electrodes in the shape of sectors fed horizontally towards each other by electromagnetic controlling apparatus.

Incandescent Electric Light, N. Tesla, New York, 514,170. Filed Jan. 2, 1893.

Claim 1 follows:

In an incandescent electric lamp, the combination of an exhausted globe, a refractory light-giving body therein, a conductor leading into the globe and connected to or supporting the said body, and a conducting screen surrounding the said conductor.

Electric Arc Lamp, R. M. Hunter, Philadelphia, Pa., 514,229. Filed May 9, 1893.

Employs carbons placed at an angle to each other, means for moving them toward one another and a device to rotate one of the carbons upon its axis.

Electrolier, E. E. Clift, Philadelphia, Pa., 514,305. Filed July 1, 1891.

Globe Holder for Arc Lamps, J. T. Dempster, Summit, N. J., 514,417. Filed Feb. 13, 1893.

Electric Arc Lamp, W. B. Luce, Brookline, Mass., 514,425. Filed March 16, 1893.

Has for its object to support the upper carbon so that it will be moved to establish the arc by means of an electromagnet in the main line circuit, dispensing with a low resistance solenoid.

Measurement :—

Inductive Mechanism for Electrostatic Instruments, W. E. Aryton and T. Mather, London, Eng., 513,975. Filed May 1, 1893.

Employs a skeleton needle of light periphery and curved fixed sheet inductors embracing both faces of the needle peripheries.

Electrical Measuring or Indicating Instrument, S. E. Hitt, Rockford, Ill., 514,075 Filed April 7, 1893.

Claim 1 follows:

An electrical measuring or indicating instrument arranged in connection with a spherical magnetic shield entirely surrounding the same and adapted to protect the instrument from exterior magnetic influences.

Electric Meter, C. Rabb, Kaiserslautern, Germany, 514,131. Filed Jan. 21, 1893.

Claim 1 follows:

In electric motor meters, the combination of a revolvable armature lying in a shunt and consisting of solenoids, solenoids comprising the magnetic field and a damping disc.

Temperature-Compensating Device, W. H. Bristol, Hoboken, N. J., 514,258. Filed Oct. 31, 1893.

Consists of a resistance and a thermometric device automatically maintaining the resistance constant under variations in temperature.

Instrument for Measuring and Regulating Electrical Resistances, G. B. Lawrason, New Orleans, La., 514,325. Filed Juue 31. 1893.

Acts upon the principle of the Wheatstone bridge with a modification whereby increased range and accuracy of measurement may be obtained.

Metallurgical :—

Method of and Apparatus for the Electrodeposition and Refining of Copper or Other Metals, L. S. Randolph, Baltimore, Md., 514,275. Filed Aug. 24, 1893.

Process of Electrolytic Separation of Nickel from Copper, P. De P. Ricketts, New York, 514,276. Filed Apl. 20, 1892.

Miscellaneous :—

Organ, R. Hope-Jones, Birkenhead, Eng., 514,146. Filed Aug. 8, 1892.

Insulated Pipe Coupling, E. E. Clift, Philadelphia, Pa., 514,304. Filed Oct. 10, 1892.

Electrode for Use in the Manufacture of Chlorine and Caustic Soda, J. Greenwood, London, Eng., 514,318. Filed Jan. 10, 1893.

Railways and Appliances :—

Conduit Electric Railway, R. C. Beardsley, Lafayette, Ind., 514,056. Filed Jan. 23, 1893.

Claim 1 follows :—

The combination of the slotted conduit and the switch boxes arranged alongside the same, electric switches in the boxes, movable parts of which project into the conduit, and removable covers for the boxes upon which a portion of the switches is mounted.

Electric Car Truck, C. F. Winkler, Kingston, N. Y., 511,109. Filed May 22, 1883.

Relates especially to means for mounting the motor flexibly upon the truck.

Closed Conduit Electric Railway, F. M. Ashley, Hawthorne, N. J., 514,112. Filed Dec. 23, 1892.

Claim 7 follows :

In an electric railway, a sealed conduit, a switching device moving in said conduit, means for maintaining a pressure of air in the conduit and an air lock at the end of the conduit through which the switching apparatus may pass.

Electric Railway, F. M. Ashley, Hawthorne, N. J., 514,113. Filed Dec. 23, 1892.

Employs a hanger at the joints of the insulated section of trolley wire consisting of two metallic plates bolted to the opposite sides of a block of insulating material and respectively connected to the ends of the sections.

Electric Railway Conduit, F. M. Ashley, Hawthorne, N. J., 514,114. Filed Dec. 23, 1892.

Employs a normally insulated conductor which is brought into contact with the feed wire by the attraction of a magnet on the car.

Electric Railway, O. A. Enholm, New York, 514,120. Filed Oct. 3, 1892.

Employs a conduit divided into two longitudinal compartments, one sealed and the other open, a circuit controller running in the sealed compartment, a collector running in the open compartment and electromagnetic apparatus carried with the collector and controlling the movement of the circuit controller.

Underground Electric Conductor, H. A. Seymour, Washington, D. C., 514,133. Filed Aug. 30, 1890.

Claim 1 follows :

The combination with a tube flexible on its under side, of an electrical conductor located within the tube, and supported therein out of contact with the inner walls of the tube, and electrical contacts secured to the under side of the tube and adapted to be lifted into contact with the electrical conductor by an under-running trolley.

Closed Conduit for Electric Railways, H. A. Seymour, Washington, D. C., 514,131. Filed Aug. 29, 1892:

Similar to No. 584,133.

Motor Controlling Device for Electric Locomotive, S. H. Short, Cleveland, O., 514,135. Filed Jan. 9, 1890.

The invention consists in two operating shafts connected with switches for reversing the motor and varying its speed.

Electric Trolley Wheel Shield, H. S. Pruyn, Hoosick Falls, N. Y., 514,274. Filed May 10, 1893.

Series Electric Railway, M. A. Cattori, Rome, Italy, 514,303. Filed May 18, 1893.

Employs a conductor consisting of the insulated sections and movable conducting circuit breakers in the gap between each two sections adapted to be operated by the locomotive to open or close the gap.

Trolley Wire Shield, L. Eschner, Philadelphia, Pa., 514,358. Filed April 30, 1892.

A continuous shield covering the trolley wire and protecting it from contact with other wires.

Switches and Cut-Outs :—

Cut-Out Block, E. J. McEvoy, New York, N. Y., 514,018. Filed July 29, 1893.

Rheostat, J. T. Birch, Pittsburgh, Pa., 514,301. Filed Nov. 16, 1893.

Employs two rotatable wire helices, the members of which are insulated from one another, and a contact plate movable along the helices.

HOW IT STRIKES THE LOVER OF DUMB ANIMALS.

In a recent issue *Our Animal Friends* has the following appreciative note :

> In its Electrical Transportation Department, THE ELECTRICAL ENGINEER for December 13th has two articles of particular interest to any one who cares for animals. "Electricity on the Erie Canal," by F. W. Hawley, shows that "the experiments recently made at Rochester are entirely satisfactory, and fully demonstrate the possibility and practicability of applying electricity in navigating the Erie. Canal boats, as they exist to-day, are of the type most suitable for economy. A man may be his own motor-man with the trolley system. In horse boats, the quarters of the animals and forage storage can be so reduced as to add considerably to the storage capacity." The other article is entitled "An Electric Traction System of Hauling Boats on the Erie and Other Canals." It is by Joseph Sachs, who has recently devised a system of hauling canal boats, which he and others consider a most feasible system of electrically operating canal boats. "The primitive method of operation by *pulling from the shore* is adhered to; but for the faithful, but slow and uneconomical, animal is substituted an equally sure and faithful, but more rapid and economical, electro-mechanical mule." The old-fashioned mule, we think, will be glad to have Mr. Sachs' plans adopted.

ELECTRICAL WORK IN MONTREAL.

The Royal Electric Co., of Montreal, Canada, through their general agent, Mr. D. A. Starr, have closed an important contract with the Montmorency Electric Power Co., of Quebec, for a large alternating plant to replace the old one. The station of the latter company is located at Montmorency Falls, six miles from the City of Quebec. The entire water power of the falls which is one of the grandest in the world, is owned by the company. The available head is 160 feet. A new power house has just been erected under the superintendence of the best hydraulic engineers and is to be equipped with new machinery. The water wheels are set horizontally and run at 600 revolutions per minute. Eight wheels have been installed, four of 620 h. p. each, and four of 310 h. p. each. The smaller wheels are to operate the arc plant which is of the Thomson-Houston system and manufactured by the Royal Electric Co. The larger wheels are for the alternating dynamos which have been specially designed by Mr. R. A. Ross, chief electrician of the Royal Electric Co., to comply with specifications prepared by the electrician of the Montmorency Electric Co. These alternators, which have revolving fields and stationary armatures, are the first of the type to be made in Canada and possess a number of novel features. The contract is for four 210 K. W. dynamos to run at 600 revolutions per minute. The current to have a frequency of 60 periods per second and a pressure of 2,500 volts at full load. The armatures contain no iron and the coils, which are machine wound of strip copper, are interchangeable so as to be easily replaced. Two dynamos are to be mounted upon one base and coupled together by a clutch so that they can be arranged to run in parallel or to give two-phase currents for power. Each pair is to be belted to one of the 620 h. p. water wheels. The switchboard is to be of marble and divided into panels to permit of adding extra dynamos by increasing the number of panels correspondingly. A full description of the plant will be given as soon as it is in operation. In addition to this large contract, the Royal Electric Co. have secured the order for all the transformers for the city lighting.

The officers and staff of the Montmorency Electric Power Co. are as follows: Andrew Thomson, president; F. H. Badger, Jr., general manager, and Lewis Burran, electrician.

MR. E. P. ROBERTS, of Cleveland, who prepared the specifications for the electric light plant of the Home Savings Bank Co., of Detroit, writes us that the two engines will be "Ideal"; the dynamos, switchboard and wiring will be furnished by the Detroit Motor Co., and the wiring will be Okonite in Interior Conduit. The Specifications were very complete giving the feet of wire on each floor and the total of each size, etc. There will be over two miles of No. 14 wire with less quantities of larger sizes.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

WORLD'S FAIR TEST OF WEBSTER SEPARATORS.

Messrs. Warren Webster & Co., of Camden, N. J., have issued a neat little facsimile copy of the test of their steam and oil separators made by Mr. George H. Barrus in the power house at the World's Fair. From the figures obtained it appears that the steam separator intercepted 17½ per cent. of moisture, which was, within the limit of errors, all that the steam contained. In the oil separator test one pint of cylinder oil, weighing 15 ounces was discharged into the cylinder, 86.7 per cent. of which was withdrawn from the separator, the remainder disappearing in the process of lubricating the cylinders and working parts, etc.

The pamphlet gives the full text relating to the test and is very interesting and concise. Other comparative tests were made, as the result of which Warren Webster & Co. were awarded three medals and diplomas; one for the Webster vacuum feed water heater, one for the Webster separators and one for the Williams vacuum system of steam heating.

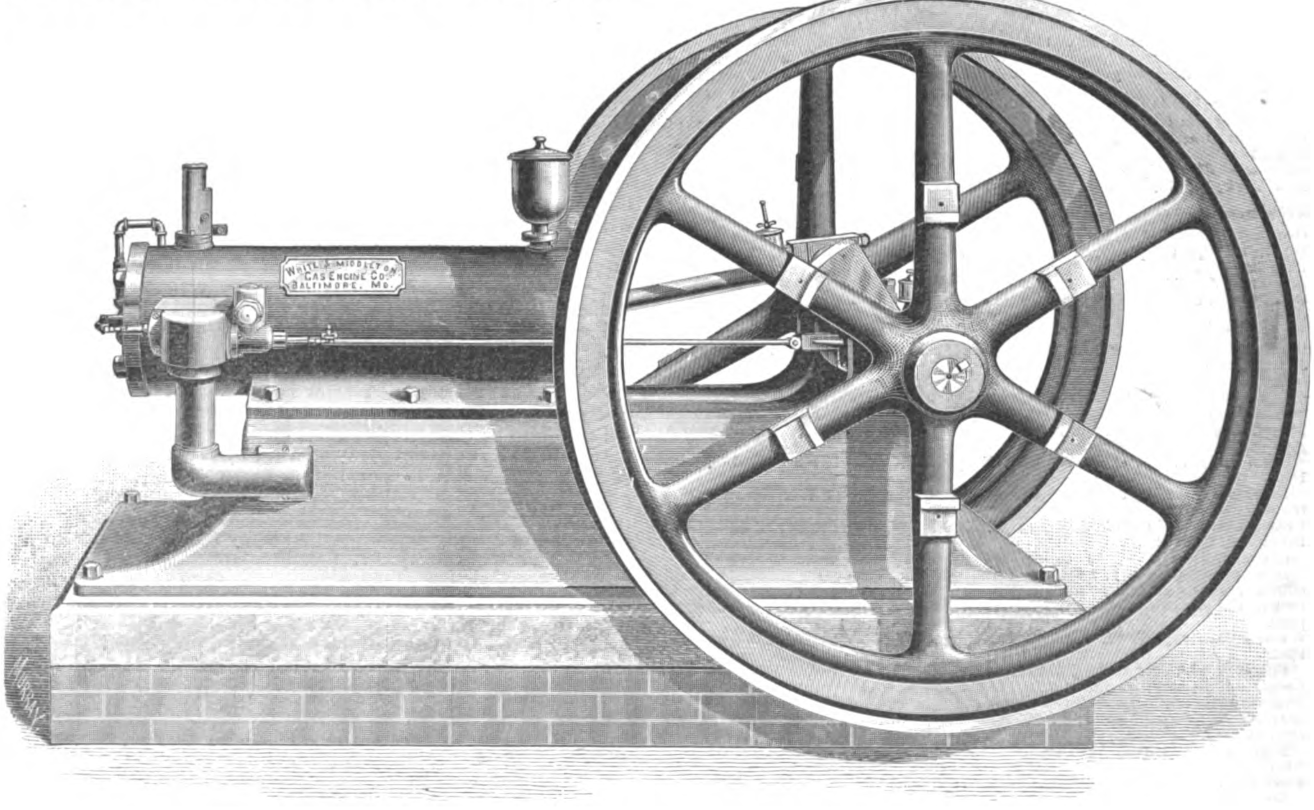
THE WHITE & MIDDLETON GAS ENGINE.

The accompanying illustration shows the general design of a gas engine built by the White & Middleton Gas Engine Co., of East Falls avenue and Pratt street, Baltimore. This engine is built in sizes ranging from 15 to 60 h. p. It has no valves and the igniter is a very simple and durable device, with no springs or mechanism of any kind to control it. The governor also is simple and substantial, attached directly to the crank-shaft, and insures regular speed under varying loads, controlling the quantity of gas for amount of work done.

The engine is furnished with automatic oilers on all working parts, and requires about the same grade of lubricating oils as an ordinary steam engine. The crank-shafts, connecting rods and other working parts are made out of the very best open-hearth forged steel and have heavy bronze metal bearings, and the workmanship is excellent. The iron castings are made from the best charcoal iron and every engine is thoroughly tested before leaving the shops. All parts are made interchangeable, so that duplicate parts can be furnished at a moment's notice in case of accident.

The company also make gas engines, in sizes from 3½ to 12 h p., in a slightly modified form. All are guaranteed not to consume more than 15 cubic feet of gas per h. p. per hour; the gas being of the quality of that used in Baltimore.

The New York agents of the company are Kimberger & Clements, 158 West Broadway.

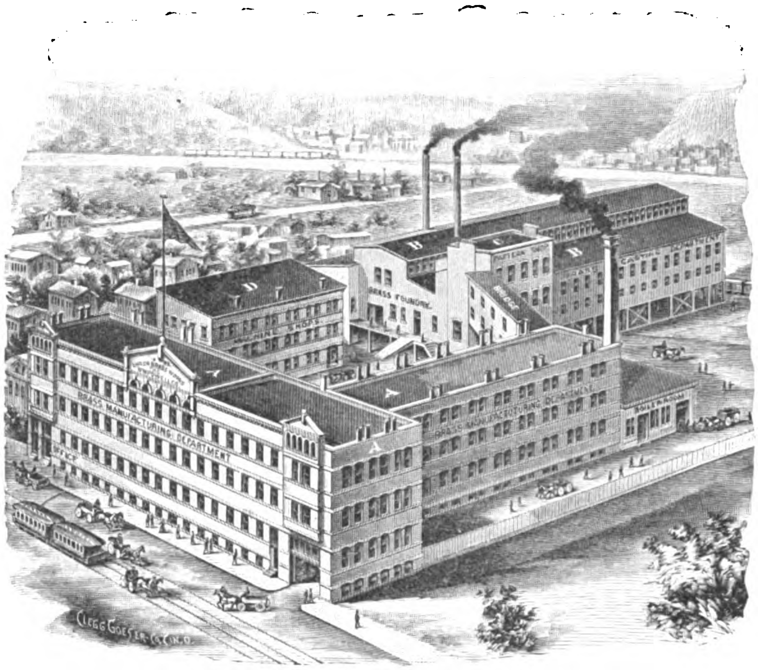


WHITE & MIDDLETON GAS ENGINE CO. BALTIMORE, MD.

THE WHITE & MIDDLETON GAS ENGINE.

THE NEW PLANT OF THE WM. POWELL CO., OF CINCINNATI, OPERATED BY ELECTRIC MOTORS.

The Wm. Powell Co., of Cincinnati, Ohio, have recently erected what is said to be the most complete plant of its kind in the country. The company manufacture brass work of kinds necessary for the thorough equipment of mills, furnaces, refineries, foundries, gas and electric light plants, etc., and their business necessitates the extensive factories and warehouses that they have built at Nos. 225 to 231 Spring Grove avenue, which are shown in the accompanying illustration.



THE WM. POWELL CO.'S FACTORIES, CINCINNATI, O.

Of the various buildings, A contains the offices, warehouse and brass finishing department, and is 119 feet wide and 3 stories high, by 175 feet long, built of pressed brick trimmed with sand stone, giving a very handsome and substantial appearance. Building B is the foundry 60 by 150 feet, and C the pattern house. Each building is separate and distinct, being isolated as much as possible for protection against fire. The engine is of 150 horse power, Corliss type, and the boiler an upright one of their own design. They have an 85 horse power generator which furnishes the current for five motors distributed throughout the various buildings and also for lighting 350 incandescent lights and 10 arc lamps.

The specialties of the company are Star valves, Star sight feed lubricators, signal and stop feed oilers, grease cups, guard steam stops, etc., and are standards of excellence and durability. They are kept in stock by supply houses throughout the country.

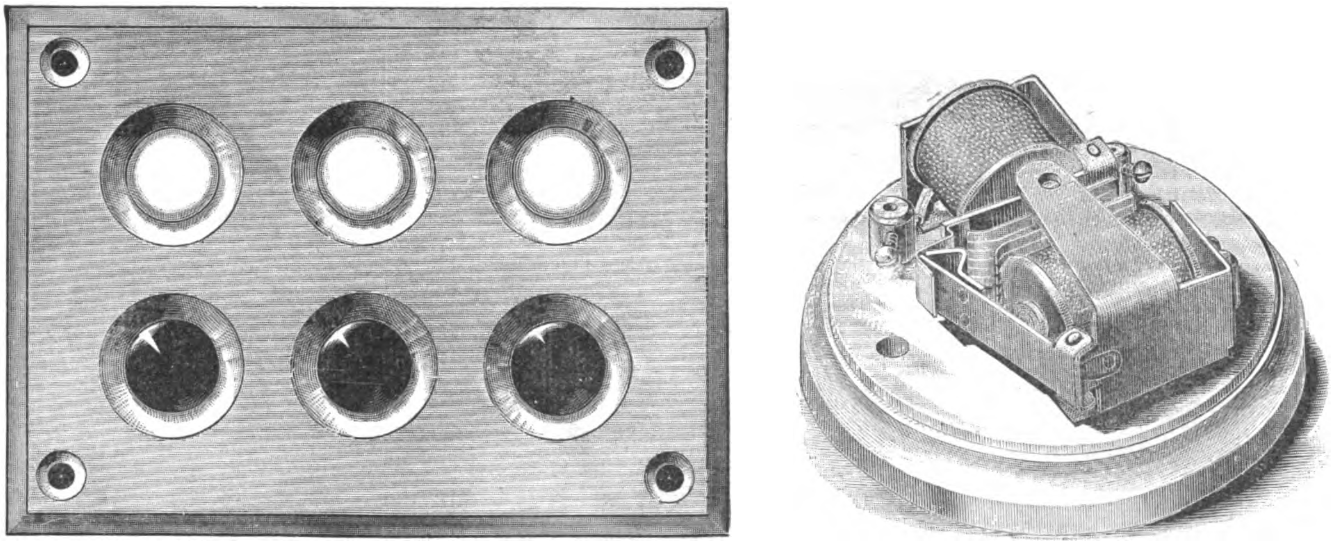
THE IMPROVED SECHRIST AUTOMATIC SWITCH.

The Central Electric Company of Chicago are introducing to the Eastern and Central trade the new Sechrist automatic switch for controlling electric lights. The system is especially adapted for controlling incandescent lights in private residences and in that capacity alone gives a great range of possibilities for convenience and comfort, besides being adapted for a number of other uses among which are the controlling of electric lights and bells for railway signaling, etc.

Fig. 1 shows a six button plate controlling three automatic switches. The metal plate, finished to match the hardware with white and black pearl buttons, is ornamental, which is one of the most important features in residence work. Instead of being collected on a metal plate the buttons may be of pearl or ivory set in the casings of the doors. The switch shown in Fig. 2 is located in some out of the way place where it cannot be seen as it requires no attention whatever.

By means of this device a person may have absolute control of any or all of the lights from any part of the house, and a button outside, which turns on the porch light, enables one to readily unlock the front door.

Immediately on opening the door the hall, parlor, library or dining room lights may be turned on or off. The hall lights may be operated from either the first or second stories, and also from each chamber. Conveniently located beside the bed may be another set of buttons controlling all the lights in the house. A convenient and novel scheme was introduced recently in a Denver residence. The wires from an automatic switch controlling the cellar lights were attached to the cellar steps so that a person going down cellar and returning, automatically turns the cellar lights on and off. The owner found that it made quite a difference in the electric light bills at the end of the month, as he had been considerably annoyed before, by the absent-mindedness of the servant in forgetting to turn off the cellar lights when they were not needed. The small bell wires which run to the various push buttons may be readily attached to the doors and windows of the house; the mere act of opening them will turn on or off the lights, or the wires may be attached to an electric mat concealed under a rug or carpet. The latter is applicable more especially as a burglar alarm.



FIGS. 1 AND 2.—THE IMPROVED SECHRIST AUTOMATIC SWITCH.

The switch itself shown in Fig. 3, is very simple in construction, being simply a locking and releasing device operated by means of two electromagnets. There are no adjusting screws or complicated parts. The circuit is attached to the switch the same as to any common switch, while the wires from the magnet spools, which are common bell wires, run to the different push buttons from where the switch is to be controlled. The switch may be operated with either an ordinary battery or by means of the electric light current. In using the latter Mr. Sechrist prefers to reduce the current, through a resistance box to the strength of an ordinary battery. The method of running the wires and connecting them to the switch may be readily understood by referring to Fig. 3. Here A A represents the back of the switch; B, a group of lights to be controlled; S, an ordinary switch loop connected to the switch; *a* and *b*, are wires supplying the reduced current; *b*, *c* and *d* are ordinary bell wires which run to the different push-buttons; C and D are two sets of buttons controlling the switch A A. Any number of push-buttons may be connected to the wires *b*, *c* and *d*, and one resistance box may be used to supply current for any number of switches.

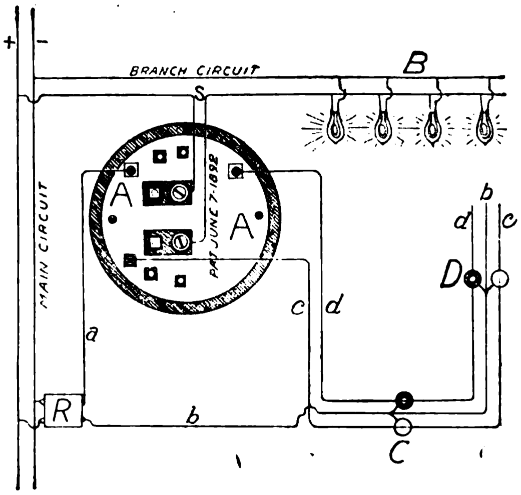


FIG. 3.—SECHRIST AUTOMATIC SWITCH.—DIAGRAM OF CIRCUITS.

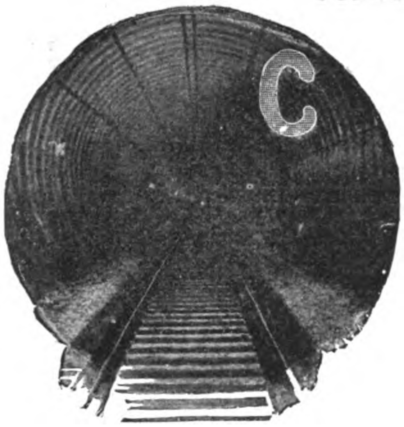
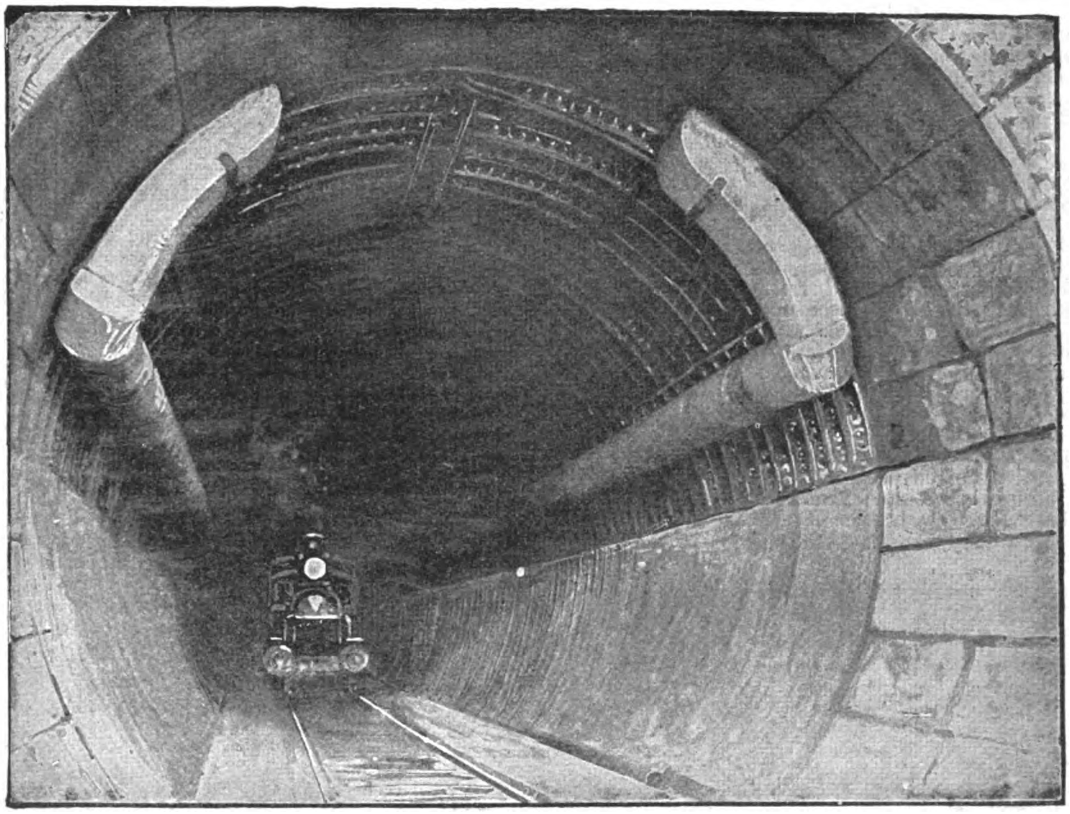
The Sechrist automatic switch system is certainly a success so far as residence lighting is concerned, and is very popular wherever it has been introduced. We have frequently described and illustrated its earlier forms, and are glad to record the perfection of so interesting and practical a device.

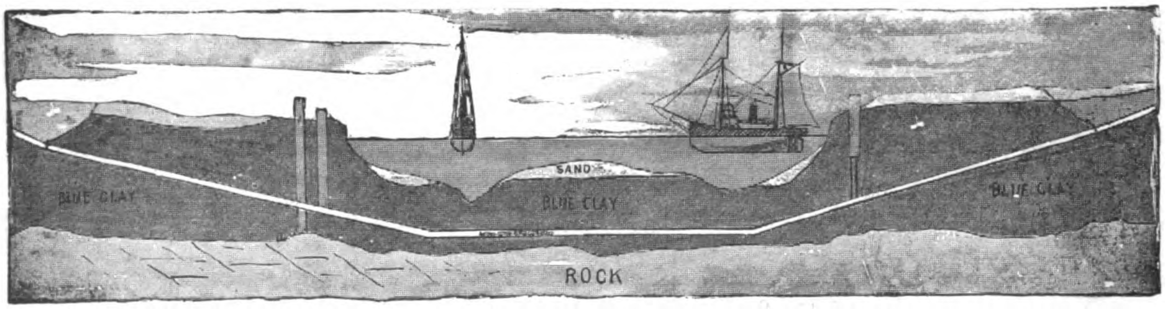
THE CONSOLIDATED ECONOMIZER COMPANY of Boston, whose headquarters are at No. 8 Oliver street, are making a specialty of installing power plants with their system of forced draft, eliminating all necessity for the usual smoke stack. This company own the valuable patents on the Lowcock, Hawkins and Hirt economizers, and guarantee a large saving in fuel and expense both in construction and operation. Economizers are becoming more popular every year in this country, and numbers of them are now in operation in electric plants, utilizing the waste gases for heating the feed water. We would call our readers' attention to their advertisement on another page, which illustrates the Consolidated Economizer Co.'s method of construction.

KERITE CABLES IN THE GREAT ST. CLAIR TUNNEL.



CANADA and this country may alike congratulate themselves upon the enjoyment of one of the largest and most successful of recent engineering feats in the magnificent St. Clair tunnel between Sarnia, Ont. and Port Huron, Mich., by means of which the water passage, across the Straits of St. Clair, at the foot of Lake Huron, is avoided, and a continuous journey by rail between the United States and the Dominion can be made, just as it is many hundred miles eastward over the Bridges at Niagara Falls and Montreal. It may be stated that the tunnel is now in full operation and is largely used by the Grand Trunk Railway for both passenger and freight service. This has some bearing on the underground rapid transit question in New York City from the fact that the tunnel, as also proposed here, is nothing more nor less than an iron tube. The diameter is 19 feet 10 inches, and the length 6,025 feet. To this is additional 5,063 feet of portal and approaches, making about a little more than two miles. Our illustration of the sectional full length view gives a good idea of the civil engineering involved in cutting the bore for the tunnel. No fewer than 4,000 cars can be daily moved through the tunnel, and no less a sum than $2,700,000 was spent in providing this great facility for travel and commerce.





The Great St. Clair Tunnel at the Foot of Lake Huron.

It is interesting to note that American manufacturers undertook a large share of the work, and that they have the satisfaction of finding their products most highly approved by the Canadian authorities. The lighting of the tunnel was done by the Edison Co. on the American side supplemented by the Ball Electric Light Co. of Canada. Packing for the cast iron segments of the tunnel, was of the "P. & B." make, furnished by the Standard Paint Co. Root blowers were supplied for ventilation, and one of our cuts shows the runs of piping made and installed by the Abendroth & Root Mfg. Co., the well known tube and boiler house of New York City. But perhaps the part of the enterprise most interesting to electrical engineers was that carried out by Mr. W. R. Brixey, the manufacturer of Day's Kerite wire and cables. That part was the making of 6,000 feet of 18 conductor aerial cable by Mr. Brixey for use in the tunnel, for the Great North Western Telegraph Co. These cables can be seen in our perspective view of the tunnel. It is needless to say that the test is a most severe one, as the cables are incessantly subjected to the deteriorating influences of steam, smoke, soot, etc. The telegraph company has, however, recently reported to Mr. Brixey on this cable in high terms of praise.

Altogether the tunnel embodies some of the best engineering of the day, and include some of the finest manufactured products, as we have shown. It is to be hoped that at no distant date, the electrical part may be added to by replacing the present big steam locomotives, reputed the biggest in the world, by electric motors of some such type as that which Mr. Frank J. Sprague exhibited in the pages of The Electrical Engineer a few months ago.

THE NATIONAL TELEPHONE COMPANY'S NEW SYSTEM OF COMPLETE METALLIC CIRCUIT.—SWITCHBOARDS FOR EXCHANGES.

The accompanying sketch, Fig. 1, exhibits the exchange system of the National Telephone Company of Boston, for which a patent has been applied and which embraces novel features entirely their own. One of the leading patent lawyers in the country has assured them that they avoid all existing patents, and therefore they are prepared to protect their customers from any damages arising from alleged infringement. They claim for their system that it is most simple, free from all complications, while its economical features will commend and place it within reach of all.

The wires used with the system will doubtless be in many instances supported upon electric light or trolley wire poles already erected. It is imperatively necessary in such cases that this metallic circuit system be used, to prevent induction. One wire is carried from the switchboard to each subscriber. A general return wire and calling wire connected to binding posts on head receiver of operator, "gridirons" the territory to be operated by the exchange—one binding post of each subscriber's instrument taps the general return wire. The key in the drawing represents cord connection in the bell box. For example, station No. 1 desires to talk with station No. 3; No. 1 takes the receiver from its holder (as shown in Fig. 2), places it to his ear and pulls down the cord at bottom of bell box; this connects him with the "calling wire" running to head receiver of operator; he then calls into his transmitter 3 on 1; the operator makes the desired connection at the switchboard; when the cord is released a sharp click is heard which determines the fact that the call has been received and desired connection made. No. 1 will now be enabled to ring up No. 3 direct and upon taking receiver from its holder No. 1 talks direct with No. 3 the operator being cut-out and unable to hear the conversation. There is no "ground" connection of any kind, a complete metallic circuit being thus secured and a large saving in wire expenditure secured over all known metallic systems now in use. The wire will be completely free from all cross-talk as this is absorbed by the general return wire.

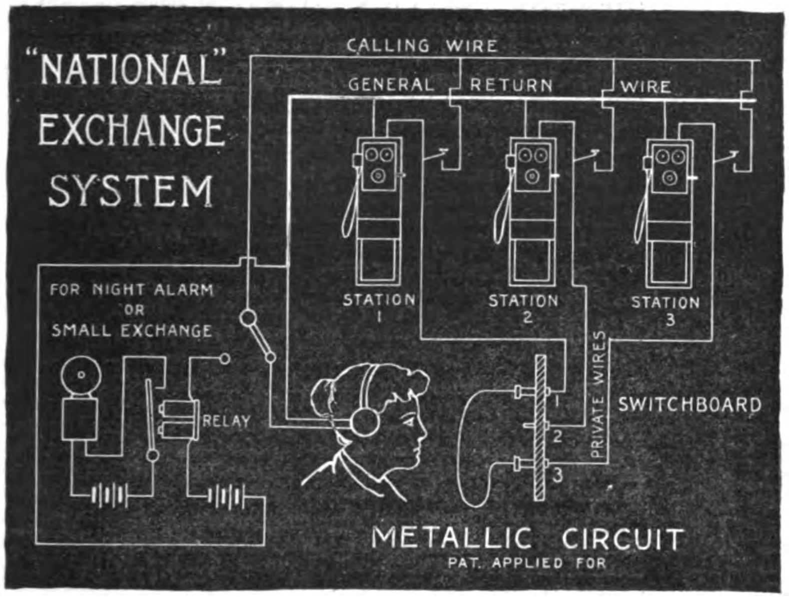
The annunciator system, also complicated switching devices, are avoided. There is nothing to prevent the use of a grounded circuit—the above system simply applying to wires supported on electric light or trolley wire poles when a metallic circuit is necessary to provide against induction.

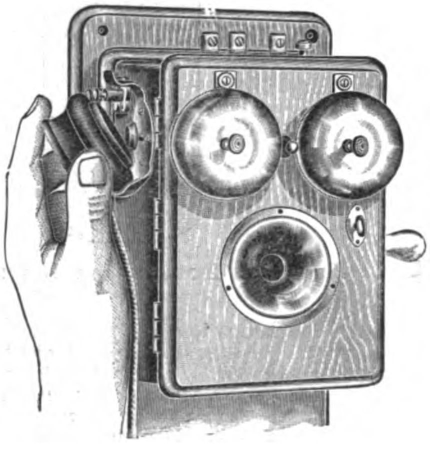
If, upon turning the crank of the bell, his own bell refuses to ring, it is evidence that telephone No. 3 is busy talking with some other subscriber, and No. 1 will have to call again later on, unless the operator should ring him up, having connected the line in the meantime. After conversation is completed, before replacing the receiver in its holder, No. 1 again pulls down the cord from bottom of bell box and calls into his transmitter, "disconnect No. 1;" this must always be done, for, should another subscriber desire to talk with No. 1, the operator would think his line still in use.

In small exchanges or central stations that may be located in a postoffice or store, or at any place where the continuous services of an operator are not warranted on the score of economy, a clerk or any other party may serve. The operator's instrument can be switched on to an alarm to sound a call when a subscriber desires to be connected, the subscriber pulling down his cord below the bell box and listening until his call is answered by "central," who will connect as requested.

The subscriber, when connected by "central," is enabled to do his own ringing up, as a call is not always promptly replied to. This feature alone permits the permanent operator to attend to answering calls, making connections without losing time in ringing bells and waiting for delinquents. This will also apply to a clerk or other party acting as operator; they will simply connect the wires, leaving the subscriber to do his own ringing up. The subscriber is also assured of the fact that if he cannot ring up the party wanted, it is by no means the fault of central office.

As above stated, metallic circuits must be used in connection with an exchange system if electric light or trolley wire poles are to be utilized or are near by. The wire used should be of No. 14 or 16 gauge hard drawn copper, which is the cheapest wire in the end. The National Telephone Company are prepared to furnish them with necessary porcelain insulators, etc., at market rates.





Figs. 1 and 2.—The National Telephone Company's New System of Complete Metallic Circuit.

THE METROPOLITAN ELECTRIC EQUIPMENT COMPANY.

This company has been recently organized to perform all kinds of electrical work appertaining to buildings including tubing, wiring, electrical appliances and fixtures, elevators, pumps, engines, dynamos, motors, shafting and ventilating apparatus, and to contract for the complete or partial equipment of buildings, using the system of the Edison Electric Illuminating Co. of New York.

Mr. Maurice T. Ward, the president, although a new comer in the electrical field, has had a business experience in this city of over twenty years. He is a member of the Produce, Maritime and Consolidated Stock Exchanges, and is well and favorably known in the commercial world.

Mr. D. Colombani, secretary and treasurer, has been for many years identified with the Edison Electric Illuminating Co. his specialty being the equipping of fashionable residences, churches, and theatres, in which, it is believed, he stands preëminent.

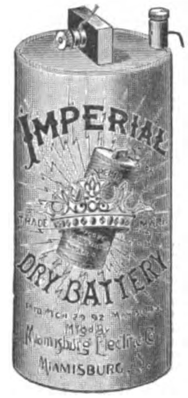
Mr. Jas. F. Hughes, the general agent, has also been connected with the Edison Electric Illuminating Co. a number of years, and has established the reputation of being most competent and successful in his particular field.

The company has been capitalized at $20,000, controlled entirely by the three officers mentioned.

The City of Minneapolis is advertising for proposals for a dynamo for the City Hall.

THE IMPERIAL DRY BATTERY.

While the "Imperial" has been on the market for more than three years, it has only been within the past year, since Mr. Wm. Burnley, its inventor, has connected himself with the Miamisburg Electric Co., that they have been manufactured in sufficient quantities to supply the demand. The result of his labors is the "Imperial," constructed on entirely new principles and a radical departure from all existing types of dry batteries. It seems easy enough to make a dry battery that will show very fair results for a short time, only; but, to hold its initial energy over long periods of time, and not have its E. M. F. deteriorate—as many have learned by experience—is not such an easy matter. But just in this particular the "Imperial," is strongest. The depolarizer used does not become a dead weight or resistance and it is not possible for the battery to deplete itself by used-up depolarizing matter, and, therefore, the possibility of internal short circuiting is eliminated. It consumes material only when the circuit is closed and will not, therefore, deteriorate when not doing work; thus giving back in actual service rendered an equivalent for money expended and possessing the superior merit of holding its initial power over long periods of time, enabling dealers to place them on their shelves without an appreciable deterioration. They are slow to polarize and quick to recuperate and not liable to rapid failure, and it is almost impossible to deplete the cell by exhaustive work.



The Imperial Dry Battery.

The cells are hermetically sealed and remain so, and will not boil over or burst the seal, and oozing of the salts from the top is entirely eliminated. Their internal resistance is small and they possess a high and quite constant E. M. F. The "Imperial" is not a closed circuit battery and should not be so used, but it is intended for all purposes for which an open circuit battery is used, and is constructed to meet all the conditions required for such a battery by the general trade. Its voltage is 1.5 and amperage from 7 to 10. Where higher amperage is wanted special batteries are made. The Miamisburg Electric Co., Miamisburg, O., are the sole manufacturers of the Imperial batteries.

NEW ENGLAND NOTES.

Prof. W. L. Puffer of the Mass. Inst. of Technology in a lecture on telephone receivers at the Wells Memorial Institute on Tuesday evening, stated that as a result of his experiments, the receiver telephone of the National Telephone Mfg. Co. of Boston, was the strongest and most powerful instrument he had found. Many receiver telephones both foreign and domestic were exhibited. The lecture was adjourned to Monday evening, Feb. 19th, when the subject of "transmitters" will be considered.

The Pettingell-Andrews Company of Boston have just made arrangements for a valuable addition to their staff in the person of Mr. Frank X. Cicott, who will hereafter have complete charge of their electric railway department. Mr. Cicott is a well known electrical engineer of wide reputation and was formerly a resident of San Francisco, as agent for Holmes, Booth and Haydens of New York. He did a large general railway supply business on the Pacific coast. He was then connected for some time with the Electric Merchandise Company of Chicago, and in 1891, started the first traction paper in the city of London, England, "The Railway World," acting as managing director of the paper for nearly two years. Mr. Cicott is still a director on the Board of Management of this paper, and is a large stockholder. Mr. Cicott's new connection will be pleasant to his many friends in the East, and with his valuable experience in railway work, and large acquaintance in the railway field, he will form a valuable acquisition to the Pettingell-Andrews Company.

THE "ACME" PORTABLE TESTING SET.

Queen & Co., Inc., Philadelphia, have just issued circular No. 520 regarding their "Acme" portable testing set. Besides containing prices and a general description of the outfit, it gives diagrammatic instructions which will prove very useful to parties handling the apparatus. The "Acme" set meets with great favor because of its compactness, completeness and simplicity.

WESTERN NOTES.

Wiley & Phelps, 1422 Monadnock Block, Chicago, will soon have one of the larger sizes of the DeLaval steam turbine dynamos in operation in that city.

Mr. Geo. McKinlock, president of the Central Electric Co., Chicago, who returned from the East recently, reports the outlook for business as very encouraging.

The Chas. E. Gregory Co., of Chicago, have just made up their first annual balance sheet, which shows sufficient net earnings to declare a substantial dividend to the stockholders.

The National Electric Co., through their agent, Mr. W. E. Bailey, have completed arrangements for an arc and incandescent electric plant for Wellsville, Mo., to be operated in connection with a roller mill.

Capt. Jno. Shay of the Chas. Munson Belting Co. Chicago, accompanied by Major H. V. Nourse, of the same company called upon their many Chicago friends last week, extolling the virtues of the "Eagle" and "Dynamo" brand of belting.

Mr. A. H. Goode, manager of the Western office of the Jenney Electric Motor Co., Monadnock Building, Chicago, reports the sale of two 650 light, and two 500 light dynamos and two 62 K. W. railway generators among last week's business.

Elkhart, Ind.—The electric light and street railway plant was sold at receiver's sale on the 7 inst. Mr. O. N. Lumbert, president of the old company bid it in for $21,000 and is said to be backed by out of town capital. The incumbrance was $75,000.

Taylor, Dee & Mack, Chicago, dealers in general electrical supplies have just added a very complete assortment of main line, double pole station switches to their stock. This firm is also the exclusive agent of the Solar Carbon Co. and Chicago agent for the well known "American" lamp.

The Lunkenheimer Company, of Cincinnati, have issued a neat little folder in which some of their newer valves are well illustrated. These have the well known "Lunken" renewable seat gate, and are claimed to be simpler, stronger, more compact and heavier in proportion than any other form of gate valve in use.

The Western Telephone Construction Co., Monadnock Building, Chicago, are moving into more commodious quarters on the fifth floor, where they will be better able to take care of their constantly increasing business. The recent trial of their magneto telephone transmitter between New York and Chicago is said to have been a great success.

Telephone Business.—As a direct result of the recent expiration of the Bell telephone patent may be mentioned the incorporation of a number of exchanges. Hardly a week passes but several telephone companies spring into existence. The Newark & Millington Telephone Co., Newark, Ills., and the Lincoln Mutual Telephone Co., at Lincoln, Ills., are among the recently incorporated companies.

Dr. F. H. Berry, D. D. S., of Milwaukee, Wis., has lately brought out an electric dental engine and other appliances, which contains many new and novel features both electrical and mechanical. He will be pleased to forward to any address on application a beautiful illustrated catalogue of his devices, and gladly answer any questions on what is needed electrically by members of his profession.

Messrs. P. H. Carey and **E. J. Shrader** have just been appointed selling agents for the Phœnix Iron Works, manufacturers of the well known Dick & Church engines. The Western agency will be located as heretofore at 519 The Rookery. Mr. Schrader is a mechanical engineer of wide experience, having been at one time assistant superintendent of the Union Iron Works, San Francisco, and more recently manager of the mining department in the Cincinnati office of the General Electric Co. Mr. Carey is a member of the firm of Harrison & Carey and his extensive acquaintance in the street railway and electrical field will no doubt be of considerable advantage to the new firm.

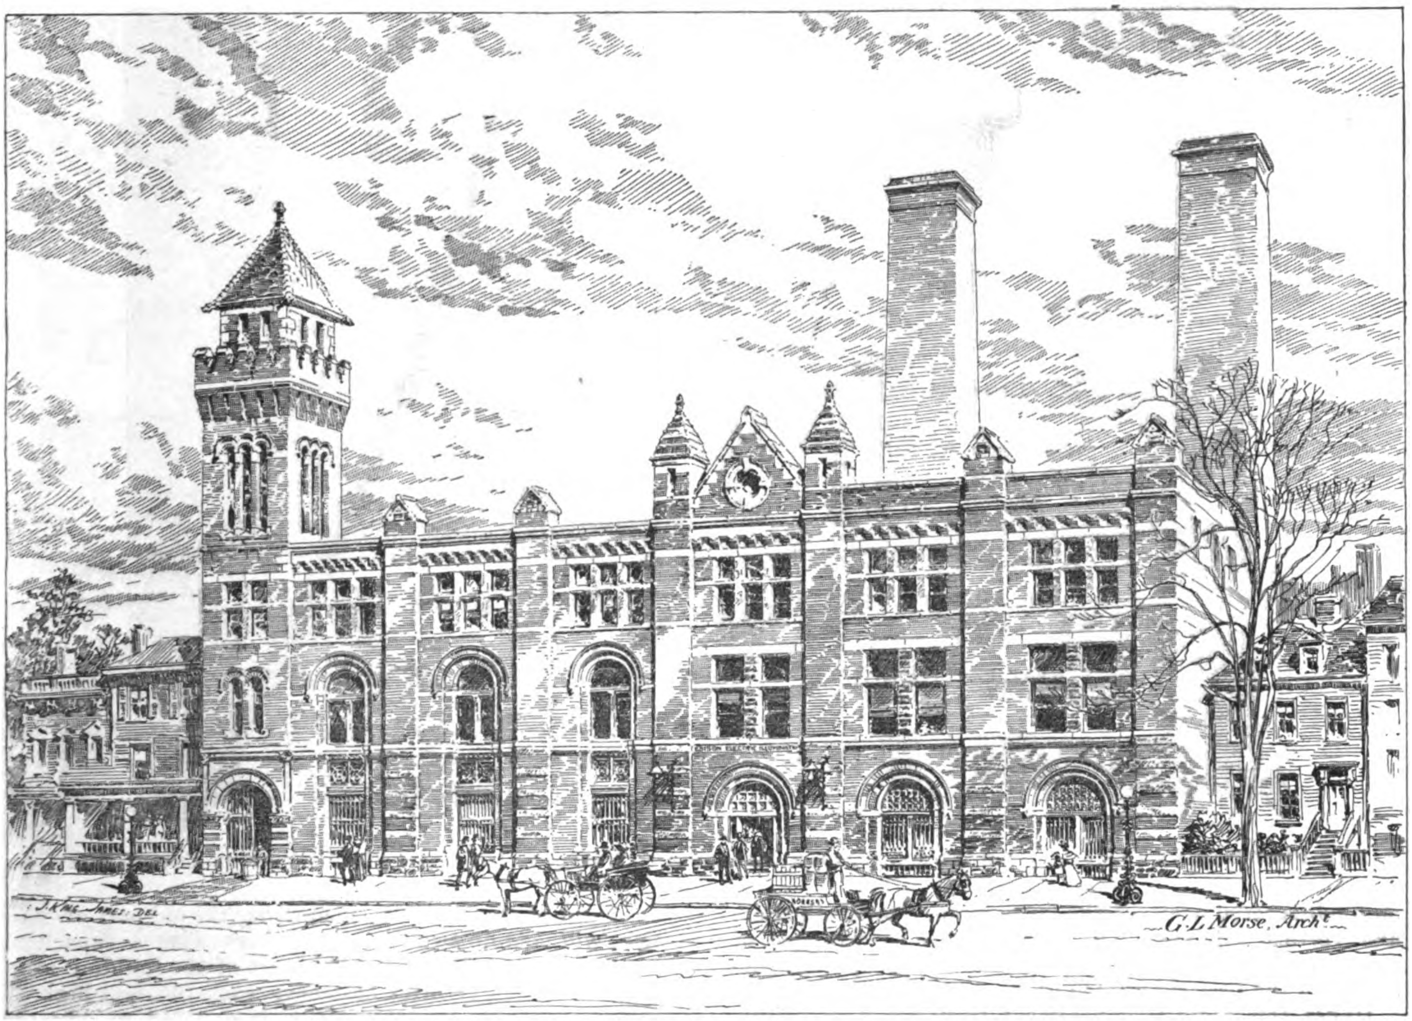
☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XVII. FEBRUARY 28, 1894. No. 304.

THE NEW FIRST DISTRICT STATION OF THE EDISON ELECTRIC ILLUMINATING COMPANY OF BROOKLYN.

THE Edison Electric Illuminating Company of Brooklyn began the designing of their First District Station on March 1, 1889, starting the operation of the plant September 1, of the same year. This station was laid out for 3,000 h. p. capacity, ample, it was then thought, to provide for at least five years' requirements. The fall of 1889, at the starting of the station, saw an equivalent of 6,000 16 c. p. lamps connected, and since then the progress has been as follows :



THE NEW FIRST DISTRICT STATION OF THE EDISON ELECTRIC ILLUMINATING COMPANY OF BROOKLYN.

1889	6,000
1890	25,172
1891	41,379
1892	75,450
1893	101,000

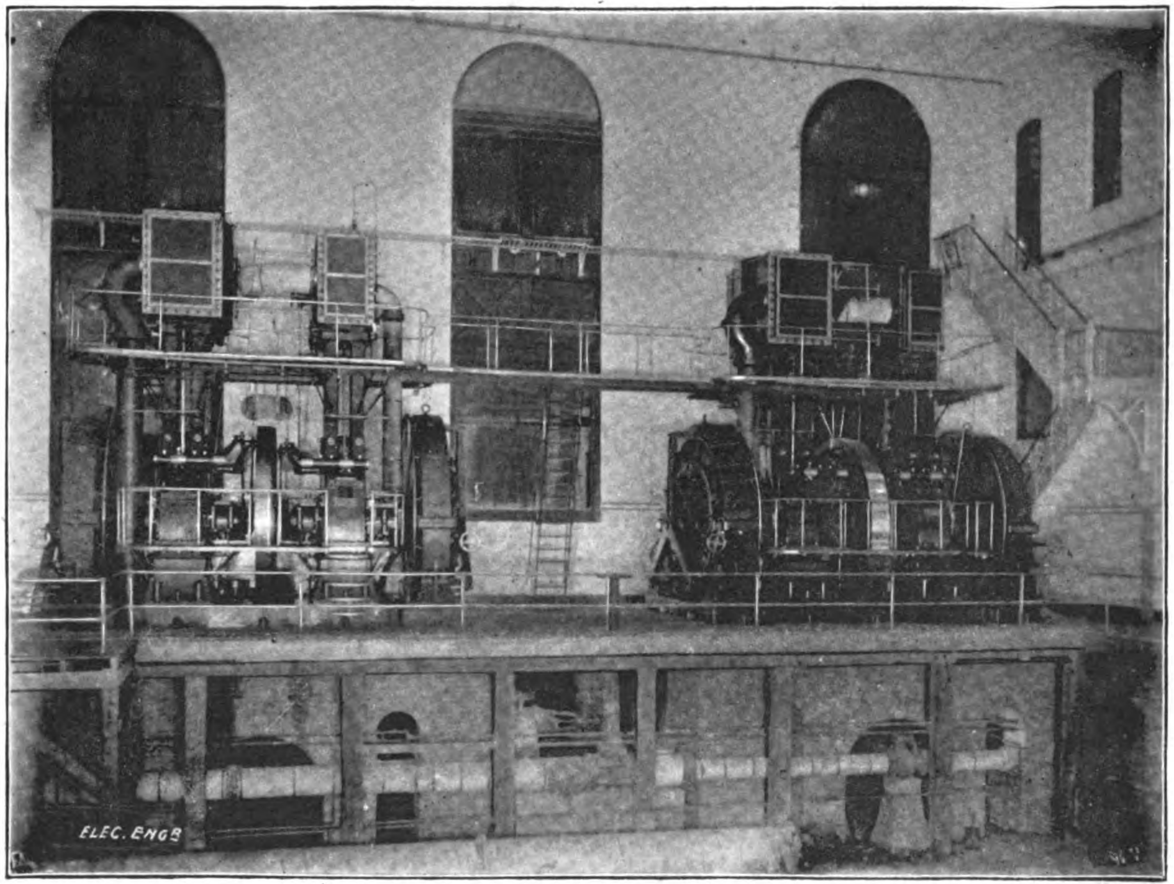
In order to keep up with this five years' increase, it was necessary to watch carefully central station construction, so that when a time came for quick action, it would not be necessary to indulge in temporary work, which is so exhausting to the funds of any company. During this time (of four years) three new stations have been built, and the original Pearl Street First District Station is now doubled in size and quadrupled in its capacity. Since the building of this station, so many improvements have arisen that we find central station construction work almost revolutionized, even down to the general character of the building, changed by the return to direct connected units, and the simplification of the distributing system as far as pressure regulation is concerned.

Plans for the new addition to the Pearl Street First District Station were commenced May 1, 1893, ground broken July 1, and the building occupied December 25. In preparing the plans care was taken to make the entire plant as now finished, consisting of old and new buildings, as complete as though it were one building, originally erected for its present capacity of 12,000 horse power.

The power room of the building in which are located all engines and dynamos, is 100 feet long, 65 feet wide, 35 feet high, and contains no columns, the ceiling being spanned by heavy girders. The room is lighted by three front and three rear windows, each thirty feet high and twelve feet wide, and as the entire interior is finished in white with wainscoating of glazed tile the natural lighting is as nearly perfect as possible, reducing to a minimum the cost of artificial illumination. At night 60 16 c. p. incandescent lamps furnish the general lighting, and each engine is individually illuminated by 20 16 c. p. lamps. The main object of having plenty of light was to detect easily any accumulation of dirt, oil, etc., the great enemy of all machinery, especially electric generators. For the same reason the floor of the room is of flint tile of a light color, such as is used in many of the European stations. For the purpose of quiet advertisement the lower part of the front windows are glazed with one pane of plate glass 9 x 12 feet, which gives to the passing public an unobstructed view of the large room, electrical gallery and vertical engines. The windows are so arranged on pivots that all panes except the lower can be opened, thus affording the best circulation of air.

Under this room is a basement twelve feet in height, which contains all the piping of the plant. Under the front sidewalk is a vault twenty feet in height, into which are brought all underground and electrical gallery conductors. A portion of this vault, walled off from the rest, contains the air and oil circulating systems, and also a large space for storage battery plant, should one be installed in the future.

On the left of the engine and dynamo room is a driveway ten feet in width, connecting Union lane (at the rear of the station) with Pearl street. This driveway affords a direct passage for all coal and ash carts, the roadway being fitted with heavy cast iron tram or track to accommodate wheels of any size or width of gauge. Under this passage is a coal storage vault of a capacity of 650 tons of coal. This coal is fed into large tunnels extending under the entire building, and in which is located all coal and ash handling machinery. Over the driveway and opening out into the engine and dynamo room is the electrical gallery, on either side of which is a brick and iron enclosed ash receiver opening into the driveway below. On either side of these ash receivers is a room about ten feet square, the one in the front part of the building being set aside for the office of the chief engineer. This room has a window opening into the large engine and dynamo room, commanding a fine view of all the machinery. A doorway also opens out into a small platform from which stairs lead to the engine and dynamo room floor. The room in the rear of the building on the gallery floor contains a staircase leading to the next floor above, and also sufficient room for a "booster" plant.

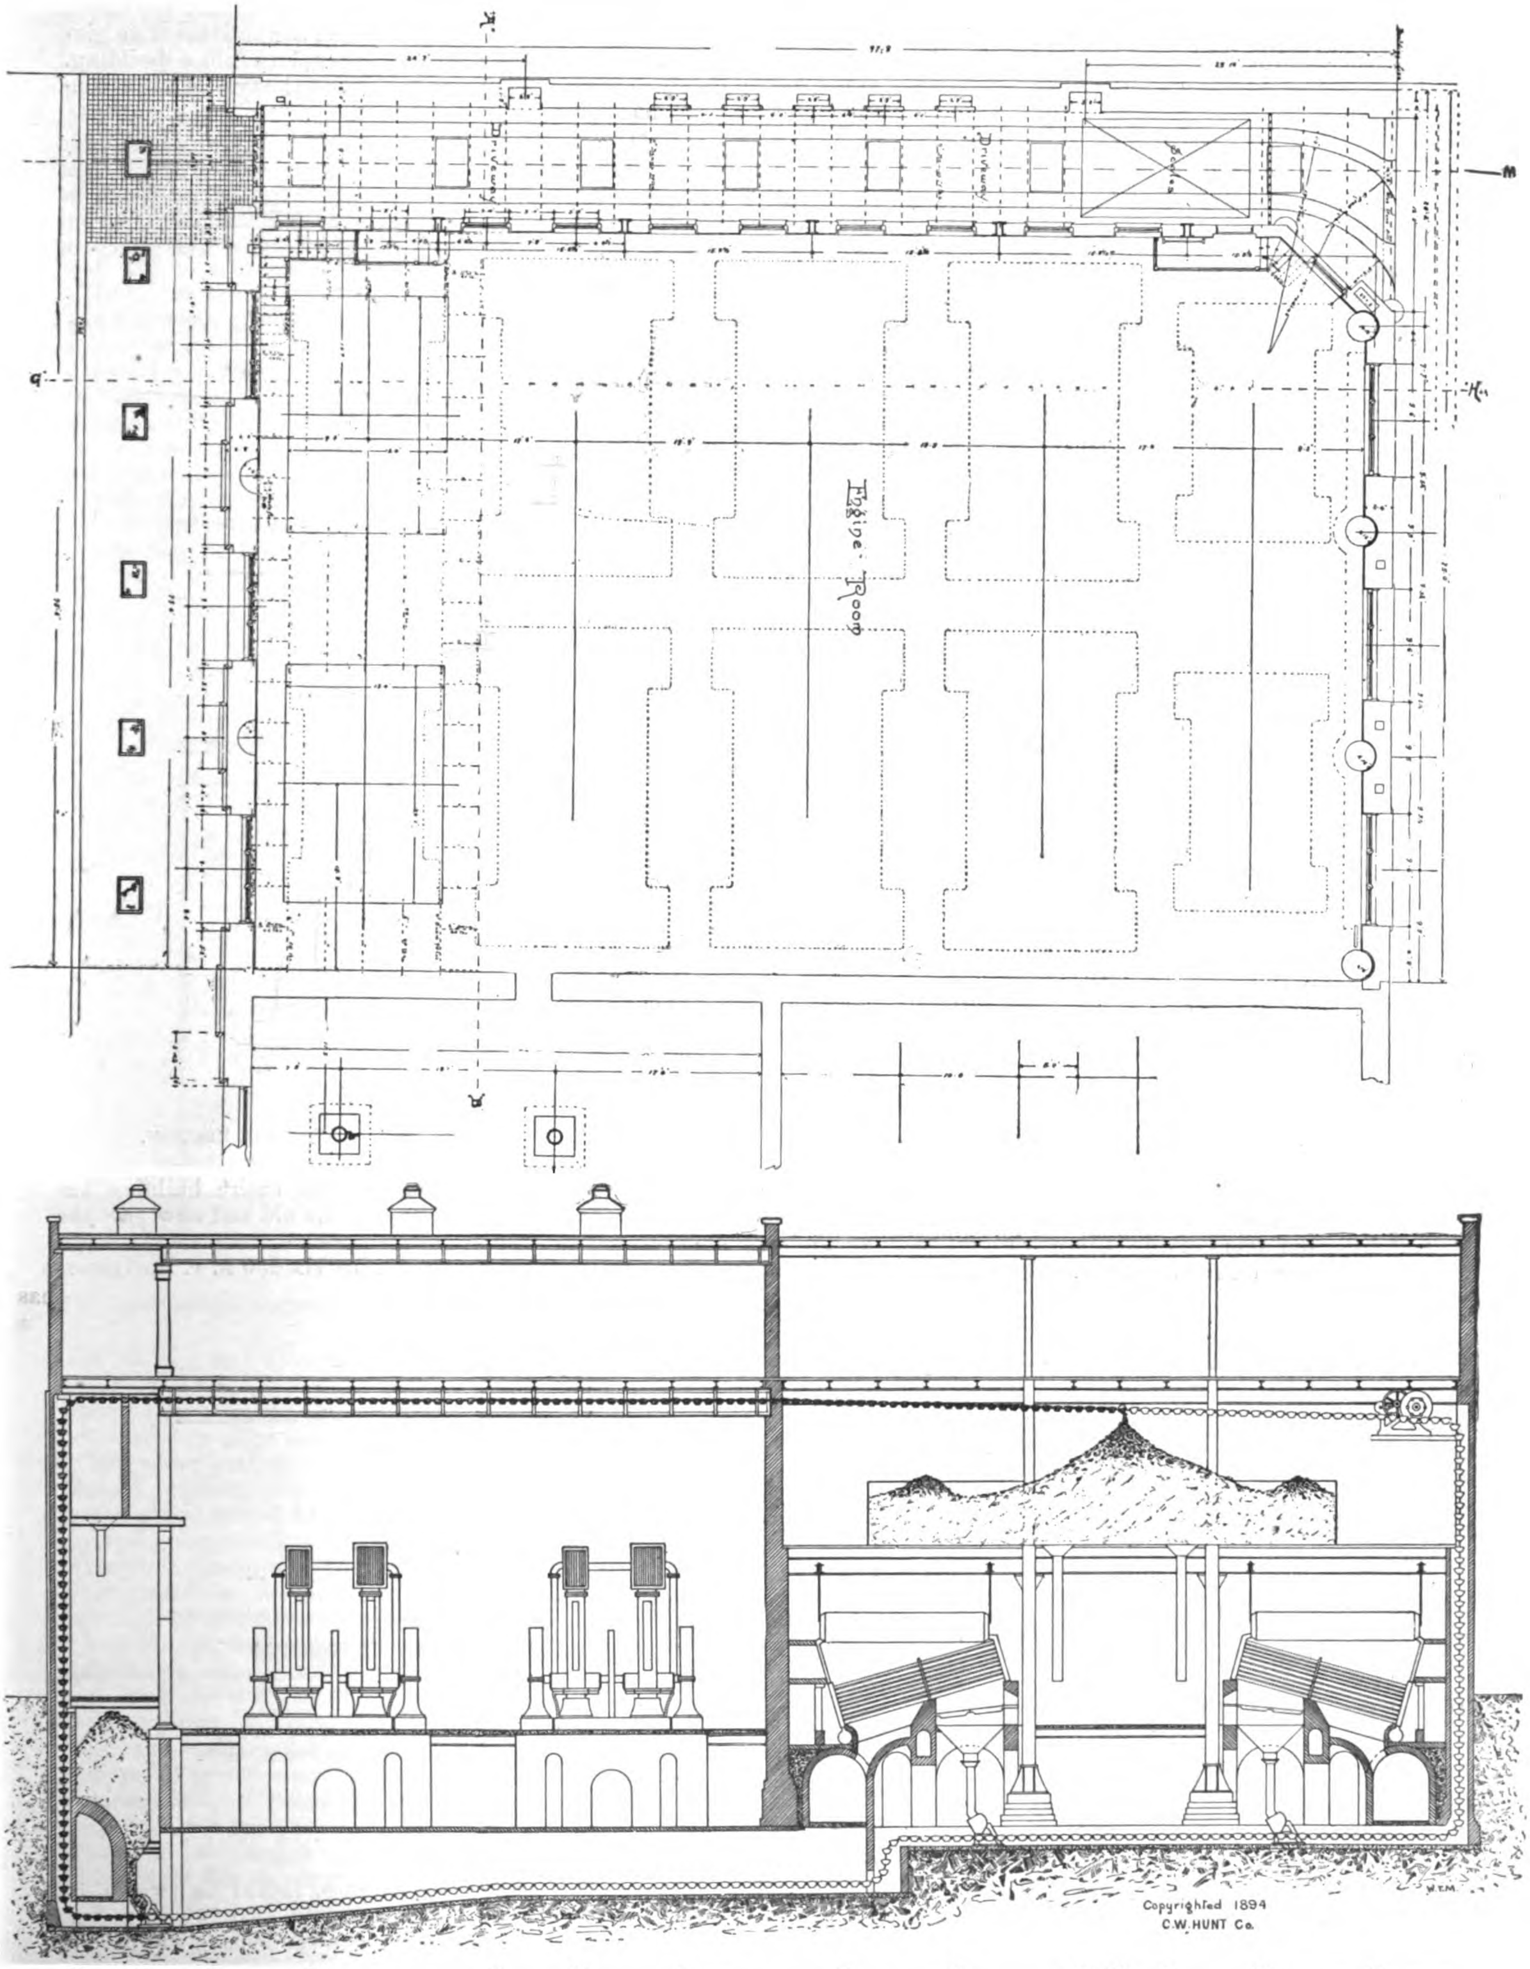


New First District Station of the Edison Electric Illuminating Company, Brooklyn, N. Y.—View in Engine Room.

The right of the building, comprising the old part of the station, will contain two floors of boilers with a capacity of 10,000 h. p. In the rear of this part of the building are located the two large brick chimneys, each 165 feet high.

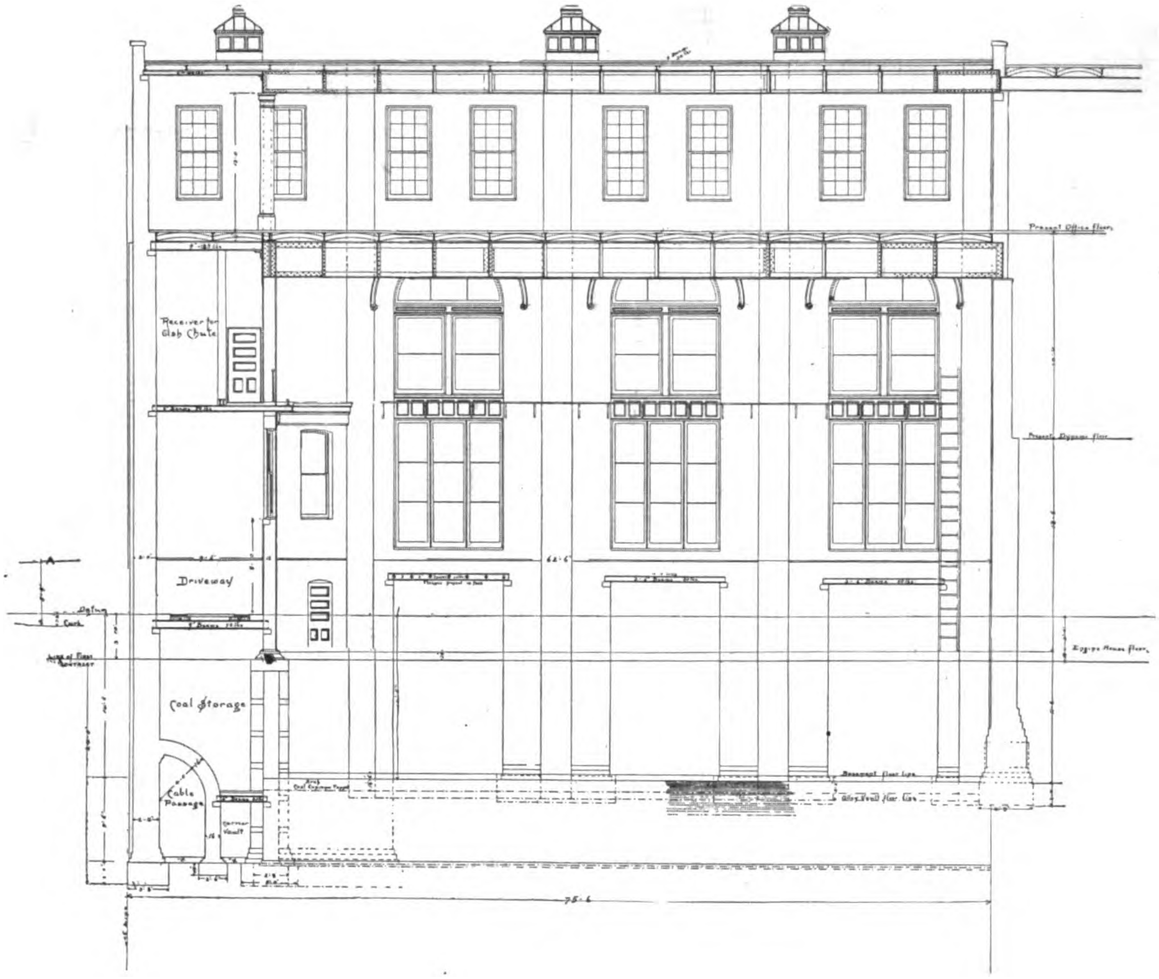
The entire top floor of the station is devoted to offices. These comprise the offices of the president, directors, secretary and treasurer, general superintendent, general office, counting rooms; offices of electrician, superintendent of steam plant, chief inspector, superintendent of underground, meter room, canvassers' room, testing room, emergency room, storerooms, machine shop, arc light room, toilet rooms, and extra space, left to accommodate future increase.

The station is absolutely fire-proof, the partitions of the office being of iron and plaster. The only wood used in the building is found in the window and door-frames, and a small area of flooring, almost all floors being of tile, iron, or cement. Care was taken in the design and construction

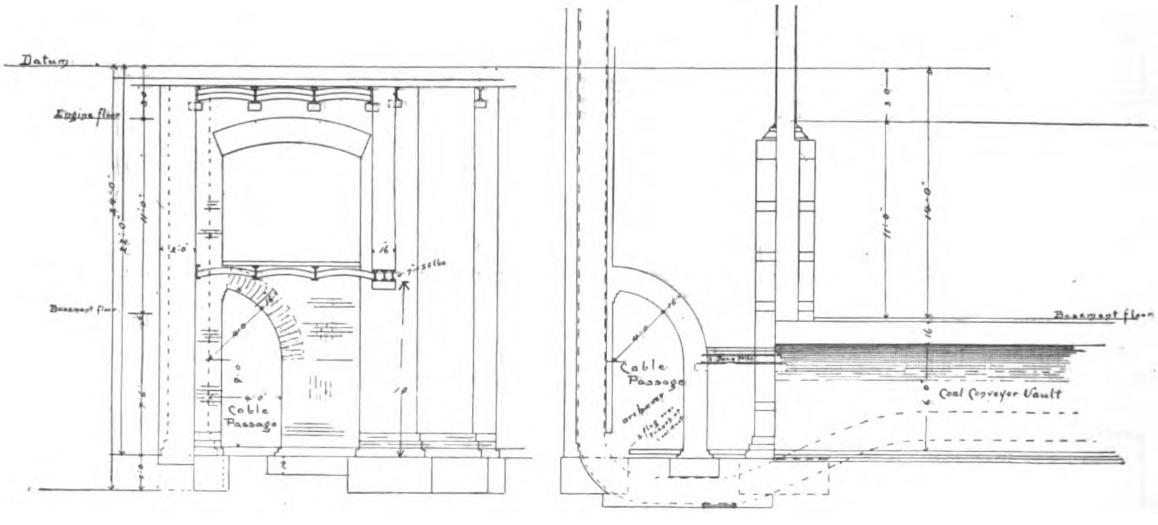


NEW FIRST DISTRICT STATION OF THE EDISON ELECTRIC ILLUMINATING COMPANY, BROOKLYN, N. Y.—GROUND PLAN AND SECTION SHOWING HUNT COAL CONVEYING SYSTEM.

of the building to provide, as far as possible, conduits for all wiring, and consequently the building is tubed for telephone, telegraph, call bells, light and power, and large accessible recesses were left for plumbing. The building on the sides and rear is protected by fire-proof shutters, and fire-proof doors divide it into sections, each containing a large water outlet and hose. Special care was taken in rendering floors and partitions of offices sound-proof, and particular attention was paid to the heating and ventilation. Thus is secured the advantage of having the offices in the main station of the Company, at the same time giving them all the benefits of a modern office building. Above the roof rises a tower about thirty feet high containing oil tanks. The front of the entire building has been slightly altered so as to give the old and new part the appearance of one building.



New First District Station of the Edison Electric Illuminating Co., Brooklyn, N. Y.—Vertical Section.



Details of Cable Passage and Coal Conveying Vault.

This station at present contains six 250 H. P. Ball cross-compound non-condensing engines, belted to twelve 100 K. W. Edison bipolar generators, and two 750 H. P. Lake Erie vertical cross-compound non-condensing engines, direct connected to two pair of 200 K. W. Edison multipolar generators. The Ball high speed engines are now being removed to another station and additional direct connected units installed, the estimated capacity of the plant being 12,500 H. P. nominal rating.

The boiler plant of the station is to be supplied by feed pumps connected direct to the vertical engines, the present steam pumps being used as reserve. These pumps are now being fitted to the two large engines at present installed and will be in operation within the next month.

In the erection of the new building an ample coal storage has been provided, in which can be carried a constant supply of 900 tons, an increase of 650 tons over the original capacity. In addition to this, machinery has been installed, so that coal can be delivered from the coal cart to the coal storage, and then distributed to the different boilers without manual labor; and by the same machinery the ashes are automatically disposed of. The capacity of the coal handling machinery, built by the C. W. Hunt Company, is 40 tons per hour, and this can be increased if necessary.

The new building has been equipped with a complete oil distributing and filtering system. By this means oil is transferred from the barrel to an elevated tank, and distributed through the engines, etc., of the station, and thence returned to a large reservoir, filtered, and again returned to the upper tank to be used over again. This is accomplished without any manual labor, although additional means are provided for oiling in case of trouble. A compressed air system is also used whereby air under 60 pounds pressure is distributed to different points of the building. This is used for cleaning the large multipolar generators, switch board, small oil piping, etc.

In addition to the plant described above, the company is operating a second and third district station, one of 1,000 H. P. and the other of 1,500 H. P. nominal capacity. Its Williamsburg or Third District Station is furnished with triple expansion condensing engines direct connected to multipolar generators. A fourth district is at present being supplied by "booster" and tie line system from the first, and the company is erecting a temporary plant of 1,000 H. P. to furnish current to the Buffalo Bill Wild West Show during the coming season.

In regard to the financial success of the company it is only necessary to state that this January its rate of dividend was increased from five to six per cent.

THE ADAPTABILITY OF AN EDISON THREE-WIRE PLANT.

BY

James Milne

THE electrical plant of the Incandescent Light Co. of Toronto, Canada, consists of two 200 K. W. direct driven, four 100 K. W. and six 60 K. W. belt driven generators of the ordinary Edison type, shunt wound for 140 volts. The company supply light and power on the Edison three-wire system at the usual pressure and also supply power to the electric street railway company at from 500 to 650 volts to supplement the power of the latter company's station. It is not necessary to describe the working of the three-wire plant as that system is well understood; but a short description of the switchboard as arranged at present together with its manipulation will not be out of place.

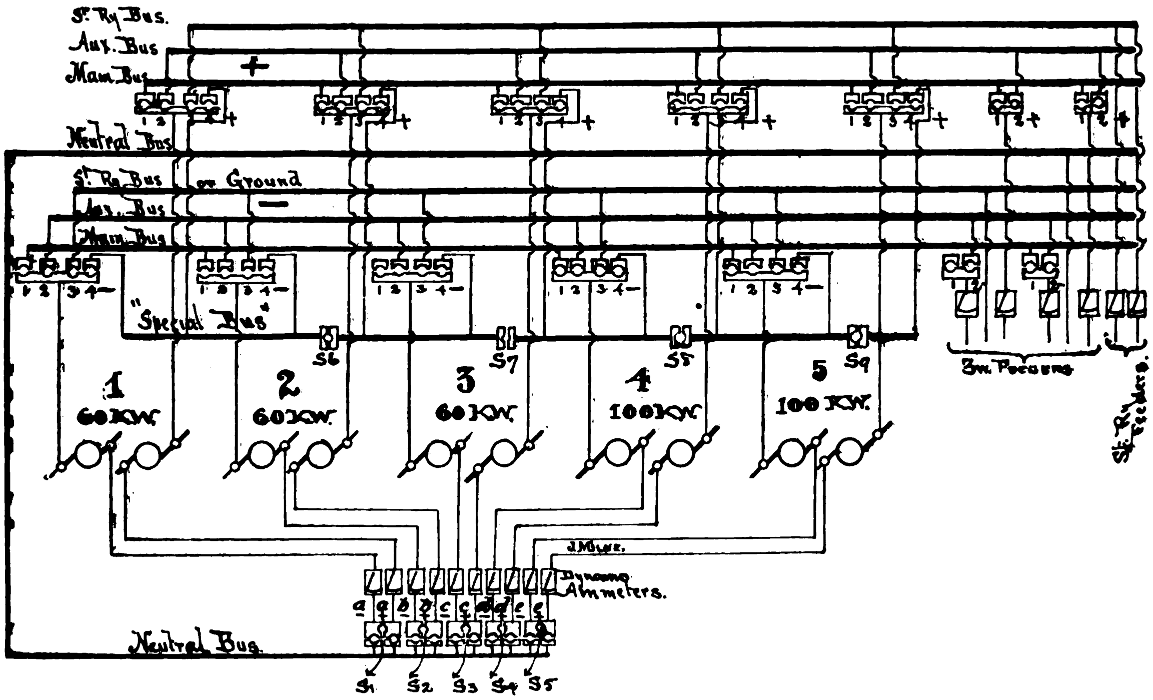


FIG. 1.—DIAGRAM SHOWING METHOD OF OPERATING 500 VOLT STREET RAILWAY CIRCUITS IN CONNECTION WITH THREE-WIRE SYSTEM.

The switchboard is arranged for running on two pressures and, by dividing the auxiliary bus, three different pressures can be run, this being necessary owing to the distribution of the load and the losses in some of the feeders at certain times. In re-arranging the switchboard for supplying current at 500 volts, it had to be taken into consideration that, for various reasons, the power could not be supplied by any particular set of dynamos, and also that the present three-wire system could not be interferred with, so that the generators could be switched in on either of the systems with the least possible delay.

The accompanying diagrams show how this is accomplished. As represented in Fig. 1, there are four switches on the + and — poles of each pair of dynamos, marked 1, 2, 3, 4, + and —, which are for the main, auxiliary, street railway and special bus bars, respectively. The object of this special bus will be seen later on. Suppose the two pairs of dynamos marked 1 and 3 in Fig. 1, are to be cut in on the street railway system: All the main and auxiliary switches on these machines, together with those leading to the neutral bus, are opened, thus cutting these machines entirely out of the three-wire system. All the machines are then brought up to the same potential and the switches s^1, s^3 (shown between the ammeters and the neutral bus) are closed. This has the same effect as closing the neutral switches, with the exception that the machines are not connected with the neutral bus. Switches 4 + on No. 1 dynamo and 4 — on No. 3 are now closed and connect the four dynamos in series through the special bus. Switch 3 — on No. 1 generator is next closed and connects the — pole of the series with the ground. All that now remains to be done to connect the generators with the street railway circuit, is to close switch 3 + on No. 3 machine. Before doing this, however, care is taken to have the pressure of the series of generators exactly the same as that of the street railway bus, which is ascertained by the voltmeter or galvanometer as in common practice.

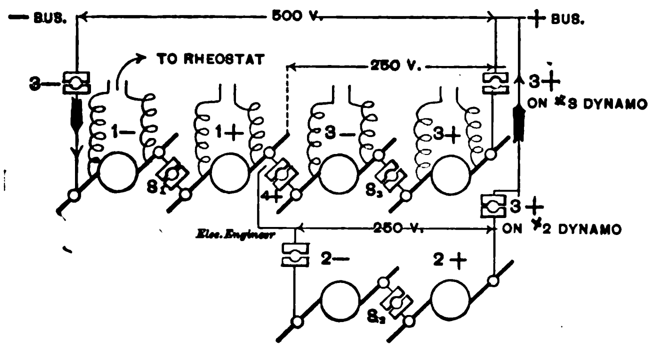

FIG. 2.

The arrangement of the dynamos in the series is shown in the upper portion of Fig. 2, the switches being lettered so as to correspond with Fig. 1. When two pairs of dynamos are running in series and it is necessary to cut in another pair to replace one of them, Fig. 2 shows the method adopted so clearly that no description is necessary. Two 100 K. W. generators can be easily switched in and the load transferred from the two 60 K. W. generators, the only precaution necessary being to have all the machines doing as nearly as possible the same amount of work.

Fig. 3 shows four pairs of dynamos in series-multiple supplying current at 500 volts and one pair supplying current to the three wire system as well. One pair of the 100 K. W. dynamos is generating 400 amperes at 250 volts and the other pair is generating 700 amperes at 250 volts. Each of the latter pair is, therefore, supplying 300 amperes at 125 volts to the three wire system while connected with the 500 volt system. This is simply a modification of the five wire system and has given excellent results. The writer was somewhat dubious as to the successful operation of this last method, but, as the load at 500 volts is remarkably steady, it was found that the variation in the pressure was so slight as to be unobserved in the lights. The only objection to this arrangement is that the negative side of the three wire system is grounded, but this in itself is not a matter of importance if the rest of the system be clear.

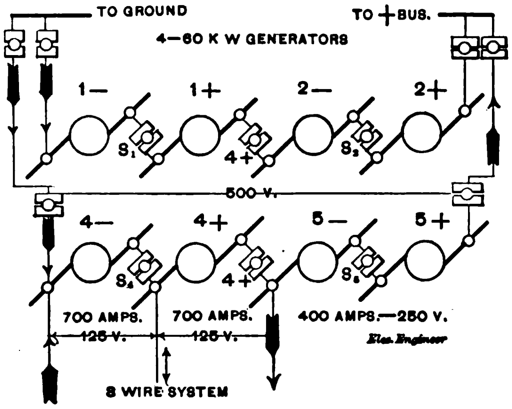

FIG. 3.

By referring to Fig. 1, it will be observed from the arrangement of the special bus that any pressure from 125 to 1,600 volts can be obtained. The latter pressure can be obtained by opening the switches s^6, s^7, s^8, s^9, and connecting all the ten dynamos in series. As there has been no occasion to run at 1,600 volts, the writer cannot say how this would operate, but from the very satisfactory results at 500 volts, it does not seem probable that there would be any difficulty in running at higher voltage.

THE COPPER-ZINC ACCUMULATOR.—V.

BY

Dr Paul Schoop

The diffusion of the electrolyte, that action that constantly brings fresh parts of the electrolyte up to the active material, becomes slower when the temperature falls. In the case of the caustic potash solution, as used with the copper accumulator, it is found, that, near 32 degs. F., it has quite an oily appearance and flows out very slowly through an opening of even ⅛ of an inch diameter. The capacity depends also upon the rate of the charging and of the discharging current. With lead accumulators, this varies to some degree according to the construction of the plates. As a rule, the more porous the active material is, the less is its capacity affected by different rates of charging or discharging currents. At comparatively high temperatures there is not so much difference as at lower temperatures; but, since dilute sulphuric acid (1 part pure acid to 4 parts of water) is still very liquid even near the freezing point, the capacity is not decreased to any serious extent even when a large discharge current is applied. But it is not so with the alkaline accumulator, which yields but a small fraction of its normal capacity under such circumstances. This is of course only of theoretical interest, since in practical service the temperature of the battery would not be allowed to run down so far. It was to be expected and experiments have proved it, that, other things being equal, if a good circulation of the electrolyte is set up, the same cell will yield a larger capacity. With the lead accumulator (pasted plates) about 15 per cent. more capacity is obtained, if the acid is kept in circulation instead of remaining at rest. A considerable gain in capacity is also obtained with the copper cell by providing for for good circulation of the liquid.

There is also the *Local Action* to be considered. As in the case of the lead cell, it is dependent upon the temperature and is slowest at low temperatures. If a lead cell stands idle after having been fully charged for several months during the winter in the open air, it will be found to contain after that time still ¾ of its regular capacity. In summer, as many weeks will suffice to bring the capacity down to ¾. The zinc in the charged alkaline cell is also attacked by the electrolyte and hydrogen gas is slowly evolved. In order to avoid great local action between the steel sheet acting as a support for the zinc, and the latter, the sheet must be well amalgamated with mercury. For this purpose, Desmazures adds mercury to his electrolyte. But even then, owing to the great surface of the support and the liability of the zinc to take up oxygen at practical temperatures, the zinc deposit does not last for nearly as long a time as the spongy lead in the lead-cell. In traction work there is no opportunity for storing up electric energy for a longer period than 24 or 48 hours, and during that time local action does not come into account so much.

During the *discharge* of the copper cell, too great currents must be avoided and to short circuit a cell is not advisable. As has been set forth in a previous article the oxygen goes to the zinc when current is taken from the battery. Whether oxide of zinc is really formed first and immediately afterwards dissolved by the caustic potash solution, or whether the zinc at once enters into some bodies formed electrically at its surface and thus dissolves, is immaterial for the present. The fact remains, that if too strong a discharging current be applied, the zinc does not dissolve readily and smoothly, but some oxidized zinc compound is found on the electrode whose dissolution is more difficult to accomplish; still, the copper cell stands pretty high discharges.

The Charging of the Alkaline Accumulator.—The charging current depends on the following factors: 1. Amount of zinc contained in the electrolyte. 2. Rate of circulation of the electrolyte. 3. Area of the cathode. 4. Composition of the electrolyte. 5. Temperature of the liquid. 6. Continuity or discontinuity of the charge. 7. General construction of the cell and electrodes.

If we investigate the conditions of charging in a lead accumulator, we would find the same conditions to govern, but it does not so much matter whether certain conditions are exactly fulfilled or not. When a lead cell contains very dilute acid, say, only about 10 per cent. pure acid, and if a comparatively large current is used for charging, at a low temperature, one finds that not half as much energy is taken up as when the same cell is charged under more favorable conditions, at a moderate temperature (70 degrees F.) with an electrolyte containing 30 per cent. of pure acid and with a rate of current calculated for a charge during 10 or more hours.

The alkaline solution must contain as much zinc as possible. For this reason, the solution of caustic potash must itself be very concentrated, since dilute solutions do not take up much zinc. If such a well made zinc solution is diluted with water or heated, part of the zinc is precipitated in the form of white oxide of zinc. It is advisable,to have the liquid circulate during the whole time of the charge. To charge with a constant current is not advisable, since at the beginning there is the maximum of zinc contained in the solution and at the end of the charge so much less as has been deposited on the cathode. Therefore the charging current must be reduced accordingly. An addition of a colloid substance (as in Mr. Swan's experiments on the deposition of copper at high current densities) has a good effect on the zinc deposit. Moderate temperature (between 70 and 100 degrees F.) is best for the zinc deposit. To charge intermittently, that is, first charge, then rest, then charge, and so on, gives better results than continuous charging. A network of steel wire is preferable to anything else as a support for the zinc. The porous copper ought to be in as much and as good contact with the copper support as possible.

ELECTRIC TRANSPORTATION DEPARTMENT.

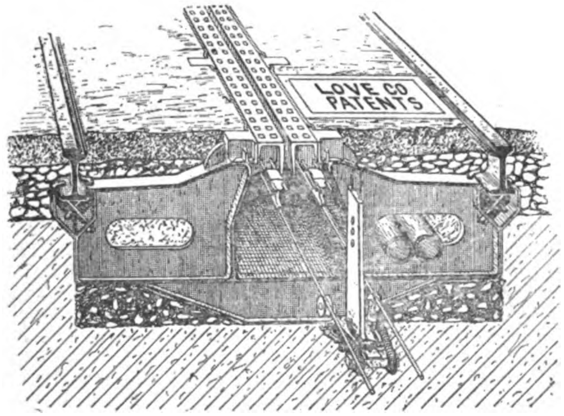
THE LOVE CONDUIT SYSTEM.[1]

BY M. D. LAW.

The Love underground trolley system in Washington is a perfect success in every particular. The cars were started March 2, 1893, and have run successfully since the current was turned into the line. The only delay occurred on June 22, when some of the strain insulators gave out from heat. They were changed to others of special make, that have extremely high insulation of pure mica, will stand 250 degrees of heat, and break at 7,680 lbs., far above anything that is required of them. There has not been five minutes' delay, from any line trouble, since they were put in.

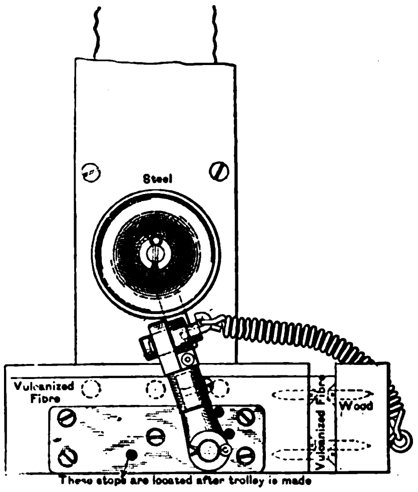
None of the line insulators have ever given out, either here or in Chicago, where the road has been in operation twenty-three months, nor do any of them show any signs of deterioration.

There has been a great cry from electricians all over the country, that trolley wires could not be operated underground, in an open conduit, for the reason that it is subjected to so much moisture, mud and slush; but I have found that, with the wire properly protected, there is no moisture on the insulator, as I have taken up the slot rail, in the worst of weather, and found the insulators dusty.



THE LOVE CONDUIT SYSTEM.—SECTION.

The success of the Love system comes from the fact, that the insulators and line are thoroughly protected, under a U-shaped slot rail, which forms a perfect steel overcoat for them, and the long lip of the slot-rail extends down far enough to carry all slush and mud below the wire and takes all the blow from the trolley, in case of the derailment of a car, so that the line cannot be injured.



THE LOVE TROLLEY AND CARRIER.

The insulator is so placed under the slot-rail, that there is a free circulation of air around it at all times, and, as there is a strong draught through the conduit, it keeps the air constantly moving.

There has never been any indication of leakage by the ammeter test, although there have been many severe storms, of both snow and rain. There has been no delay during these storms, while the overhead line has been shut down for hours at a time from line trouble.

The other principal feature in the Love system, is the trolley and its carrier. The former is an ingenious mechanical device, having all the movements of the human arm, which allows it to readily follow the wire and is so adjusted, that it will run either forward or backward.

The trolley carrier is so arranged, that the leg of the trolley is at all times held in the centre of the slot, and prevented from binding when rounding curves.

On the Washington line there are three curves, two crossovers, one double track cable crossing and three double track street car crossings. The curve at 18th and U streets is a very sharp compound curve on a two and a half per cent. grade; but there has never been the least difficulty with it.

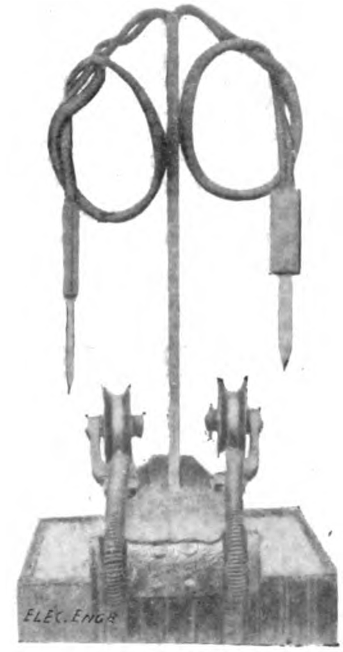
The Love Electric Traction Co. deserve great praise in the developing of their system, for it has been done under great difficulties, and from the start nearly all electricians and engineers have been against them.

---

[1] See THE ELECTRICAL ENGINEER, Sept. 21st, 1892. We are indebted to the *Railroad Gazette* for the outline cuts illustrating this article.

The Chicago road was the first one built and is a grand success, when it is considered, that no plan or model of it was ever made, and that it was built in the winter, when the thermometer was below zero, while the contract stipulated that it must be run successfully for three months without skilled labor. The fact that at the end of the three months the railway company accepted the road and paid for it, is good evidence that they considered it successful. They have also given written testimonials that they are entirely satisfied with it.

The Washington road is the second effort, and is built in every particular as it was planned, nor has it been necessary to change it in any way. The president of the Rock Creek Railway Company testifies under date of January 12, of this year, that he is entirely satisfied with its operation, and considers it a perfect success. The company also testify, that they are confident that it can be operated, as cheaply as, if not more cheaply than, the overhead system.



THE LOVE UNDERRUNNING CONDUIT TROLLEY.

A trip to Washington will show that nearly every resident is a friend to the underground trolley system.

THE MOORE MAXIMUM SPEED STREET CAR INDICATOR.

BY D. MCFARLAN MOORE.

THE passage of laws and city ordinances regulating the speed of street cars has developed the necessity for a simple automatic device which will notify the motorman, conductor, passengers, and, if thought advisable, the police and public, whenever the lawful speed is exceeded. The probability that the adoption of such a device will be made compulsory by law makes it doubly valuable.

This object can be accomplished by a great variety of means —gears and pinions, fluids, electricity, levers, governors of all kinds, various braking devices, bells, &c. The adoption, therefore, of any particular form is merely a matter of expediency, when all conditions are taken into consideration. But the demand is restricted not to an instrument indicating various speeds but to one indicating a definite speed, beyond which the car should not travel. However, if desirable, the device herewith illustrated can be modified to indicate with one adjustment any number of speeds, by the addition of an equal number of adjustment screws and bells of various tones, or an indicating dial.

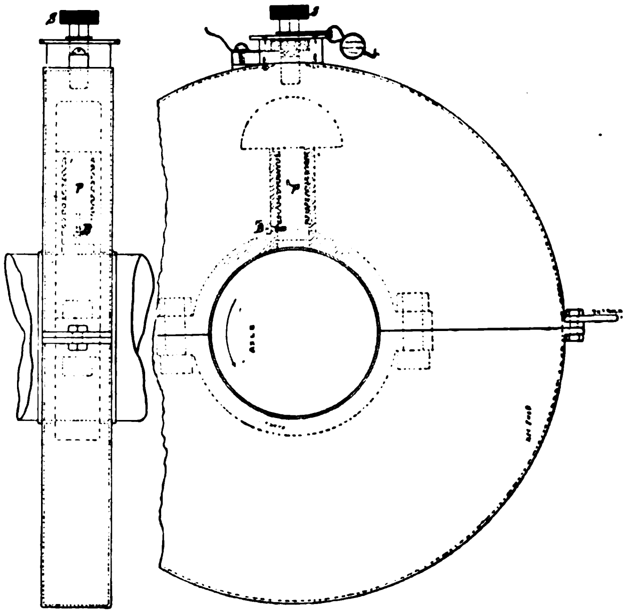
The salient points that should receive attention in the design of a machine of this nature are,—practicability of the fundamental principle of the device with special reference to misadjustment; ease of application to a car under all circumstances; minimum of space and weight required; ease of regulation; amount of attention necessary on account of mud, dust, bearings, oil or grease; durability; effect of car running in either direction; and last but not least, cost.

Electric bells in connection with a simple form of centrifugal contact device, therefore, would seem to be the best solution of the problem and the sound of bells or some other acoustic device placed on either one or both of the car platforms would indicate in a positive and unmistakable manner that the law is being violated.

The contact device in question is placed on the axle immediately between the wheel and the motor. It consists of a light cast iron gear case about 10 inches in diameter with a 1½ inch face, secured to the truck upon the axle, Figs. 1 and 2. Inside of this case is clamped a collar, from which projects radially a short pipe containing a spiral spring and plunger which makes the desired contact when acted upon by centrifugal force, varying with the speed of the car. Since the tendency of centrifugal force is tangential, the slight liability of the plunger P not working freely can be obviated by pivoting the radial pipe so that the head of the plunger can move in a short arc of its own. The proper adjustment is accomplished by means of a milled-head screw S projecting from the face of the case. This screw is accurately adjusted and sealed by an inspector, for a given speed. Should the speed of the car become much greater than that adjusted for, the ringing would be rapid but no damage would be done. This is prevented by a screw attached to the plunger and working in a slot in the pipe, which also prevents the plunger from revolving on its own axis. The contact, therefore is not injured, and the tendency of the rotary motion is to keep it clean. As the light cast iron case bears upon the steel axle it requires but little lubrication and is held in place and prevented from revolving by attaching it to the car truck.

One small wire electrically connects the adjustment screw with the bells, the current being supplied either from a battery or the trolley line.

Since the axles of street cars running at ten miles per hour with 30 inch wheels make 111 rev. per minute, it will not be necessary or advisable to use vibrating bells. Each stroke therefore will indicate one revolution beyond the maximum speed and rapid ringing will mean much too rapid traveling.



THE MOORE MAXIMUM SPEED STREET CAR INDICATOR.

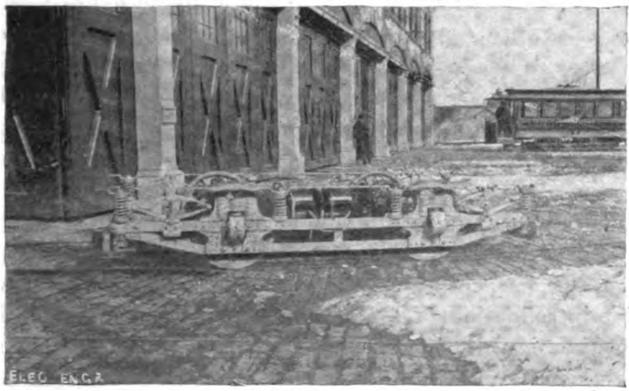
A NEW ELECTRIC LINE FOR ILLINOIS.

The Rock River Electric Railway Company, has just been organized with a capital stock of $500,000. It is proposed to connect Rockford and Dixon, thirty-eight miles apart, with an electric line, as soon as spring opens. The estimated cost of the line is $10,000 per mile, and the company propose to do a general passenger, express and mail business, and later on to handle freight. The line will be operated by water power, Fred G. Jones, of Oregon, and Jamison C. Ayers, of Dixon, two of the incorporators of the company own a controlling interest in the water power of Rock River in those cities.

The company's charter runs for fifty years and the first officers are: President, James S. Ticknor; secretary, Harry B. Andrews, and treasurer George B. King. The route is a most feasible one, the Chicago and Northwestern Railway Company having surveyed it three times with the intention of building a steam road to make closer and quicker connection with the main line at Dixon. The electric line has the advantages that the cars are able to turn sharper curves and climb steeper grades.

THE WINKLER TWIN SERIES MOTOR IN NEW YORK.

In our issue of Jan. 3 we described and illustrated the ingenious "Twin Series" motor designed by Mr. C. F. Winkler, electrician of the United Columbian Electric Co., in which two armatures revolved in magnetic fields so as to make but a single magnetic circuit. The advantages of this system were fully pointed out in that article and recent practical work seems to have confirmed them fully. Among the roads on which the Winkler motor has been put in operation is the Union Railway of New York City, one of the most influential street railroads in the country, who are making a practical test of the Winkler motor with the view of ascertaining accurately its economy and various other advantages for street railway traction.

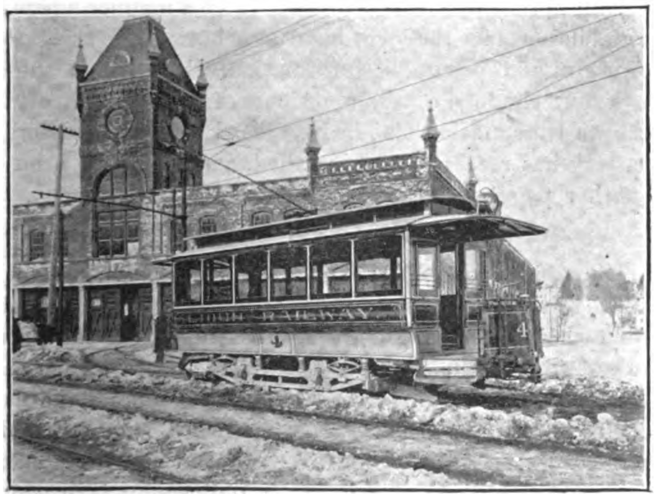


The Winkler Street Car Motor.

The United Columbian Electric Company have equipped a standard 18-foot car with its 50 h. p. motor and controlling mechanism, and mounted it on a Peckham flexible gear truck. The accompanying engravings, Figs. 1 and 2 show the truck and motors and also the completed car as now operating on the Union Road on the other side of the Harlem River. We hope to publish shortly some tests on the relative economy of this and other equipments.

The "Twin Series" motor bears out in actual service all that has been claimed for it as regards economy, flexibility and the ease with which it rides round the sharpest curves. It is also claimed to be considerably less in weight per actual horse power than any other double equipment. One of the most remarkable features of the car is the very slight diminution of speed when ascending a heavy grade.

The controlling mechanism includes a short-circuiting device for use as an emergency brake in case of danger and which will bring the car to a sudden stop without taking current from the line or causing the fuse to blow; in fact when this device is operated the trolley is cut out automatically and it is not even necessary for the motorman to wait to throw off the controller, as the device will operate equally well with the controller full on. Usually when the motors are reversed to stop the car the overload will either open the circuit at the power house or blow the fuse on the car, as in the recent terrible accident in San Francisco, and the motorman is then helpless. If in this case the car had been equipped with Twin Series motors and this device, the accident could not have occurred.

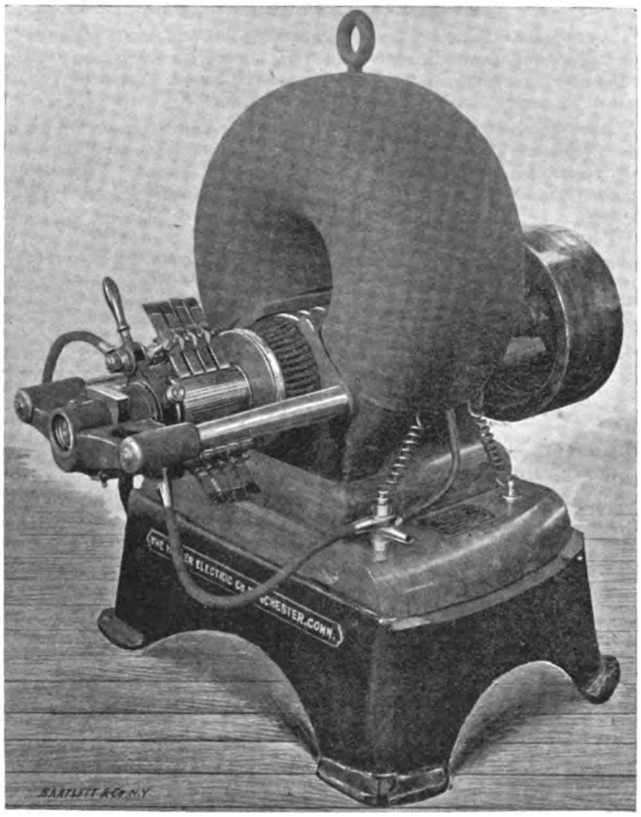


The Winkler Street Car Motor, Union Railway, New York.

THE NEW MATHER RING POLE DYNAMO AND STREET RAILWAY GENERATORS.

The Mather machines are too well known to require any detailed description but some recent improvements in the machine are well worth describing. Principal among these is the adoption of steel instead of cast iron for the field magnets. Owing to the greater magnetic permeability of this material the output of the Mather machines has been nearly doubled and their speed reduced. The accompanying engraving represents the a 31 k. w. machine of the new type, designed for 500 lights and running at 850 revolutions. The armature of this machine is surface wound, but the larger machines have toothed armatures.

Among the mechanical improvements we note a change in the self-oiling bearings. These are now constructed in such a manner that the height of the oil in the reservoir below the bearing can be readily inspected; this prevents waste of oil in filling and affords a means of watching constantly the supply of oil. This type of machine is built in various sizes up to 1,200 lights capacity.



The New Mather Ring Pole Dynamo.

As already announced by us the Mather Company has started up its plant on full time and besides its regular line of machines is actively pushing the construction of twenty-five of its new 120 k. w. street railway generators. Mr. Thomas C. Perkins, the vice-president of the company is very hopeful of the future and will represent it at the Washington Convention of the National Electric Light Assoication.

It will be the policy of the Mather Company to confine its business strictly to that of a manufacturing company, working for a manufacturer's profit and selling its machines on an independent basis to contractors, central stations, etc. Messrs. G. M. Angier & Co., of No. 116 Bedford St., Boston, are contractors for the Mather apparatus in New England.

The C. & C. Electric Motor Co., who have recently removed their works to Garwood, N. J., have now removed their old office in Greenwich street, to No. 143 Liberty street, New York.

STORAGE BATTERIES IN CENTRAL STATIONS.

THE chief object of the meetings of the National Electric Light Association is the discussion of topics which will enable the members of the Association to learn the experience of others and to profit thereby. It seems eminently proper therefore that one of the subjects which should be taken up is that of the introduction of storage batteries into central stations. It might be said that our experience in America has been too short and too meagre to permit of a discussion such as those usually indulged in at the Association's meetings, but if the subject is brought up even in a more general way it will serve the purpose of demonstrating prominently what, we believe, will be standard practice not many years hence. "How can we equalize that frightfully variable load extending over 24 hours?" has been the sigh of station managers for years. The introduction of motors has, it is true, helped to bring up the day load, and the rapid multiplication of arc lights on incandescent circuits has increased the night load, but with all this, there are but few stations whose load diagram does not resemble strongly the familiar saw-tooth. Up to the present, the central stations equipped with storage batteries in the United States can be counted upon the fingers of one hand, while in Europe there are over 175 stations equipped with batteries varying in capacity all the way from a little over 100 to over 3,000 ampere hours. We are well aware that not all American electrical engineers are agreed on the economy of the central station storage plant; but, we ask, can it be possible that the foreign engineers would continue this practice unless it had proved economical in the past, and especially in view of their well known conservatism in all such matters? We are not unmindful of the deterring effect exercised throughout the past by the long and wearying litigation in this field, and regret to note a renewal of warfare; but in spite of all this it seems hard to reconcile all the facts in this apparently studious neglect of the storage battery, except on the theory of lack of knowledge. If the members of the National Electric Light Association can find time to devote to the subject and to treat it in a manner adequate to its importance they will have added largely to their stock of useful and profitable information. We would submit as a text the load diagram of one of the stations of the Edison Illuminating Co., in New York, in which a storage battery has recently been installed, and which we print on another page.

TELEPHONE AND TELEGRAPH.

Superficial observers, and even trained students who are cognizant of the slow effect of new ideas in other fields than that of invention, are apt to assume that the net result of an invention, if it succeed, is destructive rather than constructive. In other words, they believe that the new-comer in order to make a place for itself has to shoulder something else out of the way, because there is not standing room enough for both. Such philosophy is certainly wrong. The list of old things that have disappeared under the competition of the new, is not at all extensive; hardly as long, we should say, as the list of old things to which in some unexpected manner the later ideas and influences have given a renewed lease of life. Perhaps the number of dugouts, bows, tinderboxes, sandals, and tents is not on the increase, but aside from these and a few like instances, old forms continue to perpetuate themselves indefinitely and in larger variety and quantity than ever. What is chiefly done by important innovations is to define more strictly the limits within which the ancient can be genuinely useful and efficient. That is about all. Sailing ships still swarm the seas despite steam; gas is burned in enormous quantities without material check from the rapid introduction of electric light; and there are as many tents and canoes in use to-day for pleasure as were known even when the Tartar roamed Europe or the Red Indian owned these Western waters. The telephone has made gigantic strides these ten years, but there is more telegraphy than ever, and no sign is discoverable of falling off in the number of mailed letters or messenger boys.

That the telephone should environ the telegraph with a larger area of utility one can readily understand, but such observers as we have in mind may be unwilling to believe that the telephone can actually stimulate the telegraph. Yet such is undoubtedly the case, when the matter is viewed broadly. Our own conviction on this point received an unexpected support in the remark of a shrewd electrical manufacturer recently. In conversation on the subject of the better outlook for universal telephony through the running out of the monopolistic early Bell patents, he said that the sales by his house of telephones had, very curiously, been accompanied by almost as large orders for keys and sounders. The idea of the purchasers was that if they were going to put up a line, they might as well have keys as telephones at each end; and thus the lines are being rigged up everywhere "contrived a double debt to pay." It might be said that this touches only a smaller branch, but the practice here indicated will, we venture to assert, sooner or later be carried out on the largest scale, in heavy work.

PAYING STATIONS.

We are glad to give space in this issue to a letter from Mr. W. N. Stewart called forth by our recent editorial on his paper read before the Northwestern Electrical Association. Mr. Stewart takes exception to the doubts we have expressed as to the entire correctness of his conclusion that direct current stations are the best payers, and brings forward additional statistics of stations in the State of Wisconsin to prove his case. These are valuable in so far as they show a condition of affairs which ought to be susceptible of remedy. There are so many factors governing the paying qualities of a station that it would be futile to ascribe the causes of a non-dividend paying condition to any one of these factors. This Mr. Stewart practically admits and we think that he has struck the keynote to the situation when he refers to the personal equation of those operating the plant. The best equipped station in the world would lose money with bad management, and in the management we include not only the electrician but everyone connected with the operation of the plant from the president of the company down to the fireman; while on the other hand we know of stations having apparatus built ten years ago, which are earning money for the stockholders. If it be true "that the average country electrician cannot get the best results out of his apparatus," then it is high time that the "country electrician" be retired and his work be put into the hands of those who *can* get the best results out of the apparatus. We discern in this state of affairs an opening for many of the graduates of our electrical engineering schools. These have for the most part gone into the drafting rooms and laboratories of electrical concerns until the demand in that direction appears to be pretty well filled, and the bitter experience of the last few months has served to emphasize this fact of surplusage of such talent in a most striking manner. If more of these young men, well equipped as they are, would start out after graduation with a view to fitting themselves for the management of central stations we believe that more of them would find congenial and profitable employment, and the public would soon hear less of the non-paying qualities of stations. The time has passed when it seemed to require the massive brain of a heaven-born genius to design a dynamo; and we would suggest that a fair amount of time be devoted in our electrical engineering curriculums to central station management and finance—a need which we are glad to note has been recognized recently in several colleges.

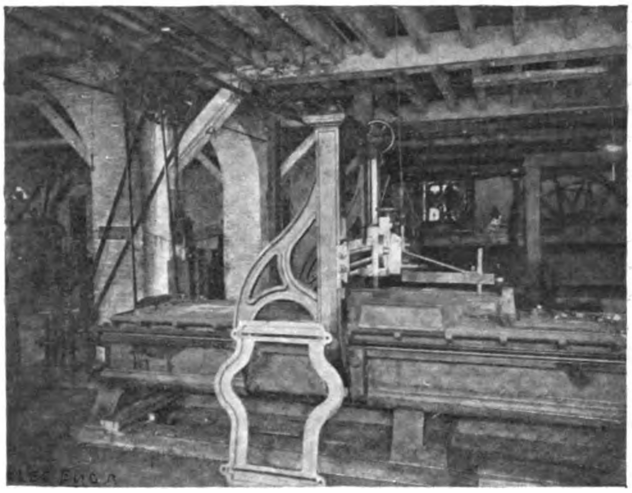
ENCLOSED HIGH-POTENTIAL ARCS.

The electric lighting fraternity throughout the country has been anxiously awaiting the results of commercial tests of that latest development in arc lighting, the Howard system, in which the arc is enclosed in a small bulb so arranged as to practically exclude the external air. We have already referred to the importance of this very interesting device to the arc lighting industry and have recently noted the practical tests on the circuits of the Hartford Electric Light Co., where the system has now been adopted. It is safe to say, therefore, that among the numerous topics laid down in the programme of the National Electric Light Association's meeting at Washington none will excite keener interest than the report to be presented by ex-president C. R. Huntley, of Buffalo, embodying the results of his own exhaustive tests of the system. Since the time of the presentation of this subject at Chicago before the International Electrical Congress last August there have been, we hear, several important improvements in the design and action of the Howard device. It is said that one change in the construction has resulted in prolonging the life of the electrodes nearly 100 per cent. Indeed, we understand that recent tests show the life of the negative carbon to be over 200 hours per inch! But the great field for the enclosed arc lies in its application to constant potential circuits, direct and alternating currents. Mr. L. B. Marks, who with Mr. L. E. Howard has been identified with the development of this system, has just devised a method of running high potential arcs on high potential circuits, and which promises to open a broad and entirely new field in electric lighting. His plan is to run 100 or 110 volt arcs directly across constant potential circuits without the intervention of dead resistance; he is thereby enabled to decrease the current to 2 or 3 amperes and without impairing the value of the light. It is obvious that results of this character are practically impossible with open air arcs, and hence they would seem to bear out our prediction that the arc-enclosing cylinder must have a wide and deep influence on the future of arc lighting. We trust that the convention will discuss and investigate this matter very thoroughly.

THE LA ROCHE ELECTRIC WORKS, PHILADELPHIA, PA.

I.

LARGE industries very rarely spring into existence fully equipped and well backed. They and their founders have literally to work out their own salvation with fear and trembling. In electrical development this has been, and is still, painfully true. When the history of the electrical industry in America shall some day be gathered into a volume adequate to do it justice it will be found that the majority of the large and successful concerns now in existence were the outgrowth of the individual efforts of poor and struggling inventors—of men who, in addition to the hard work of thinking out new ideas and constructing their apparatus and devices with their own hands, had the still harder task of convincing the public of their utility and the capitalist of their paying quality as business enterprises. Among those pioneers who have had to do battle with such fearful odds was Mr. F. A. La Roche, the founder of the La Roche Electric Works, of Philadelphia, who from the smallest beginnings in 1880 has succeeded in creating a business now requiring for its handling a seven story building covering several acres of floor space, and equipped to build machines up to 10,000 lights capacity. Postponing for the present a narrative of the interesting history of the La Roche company we shall at once take up the description of the new works which the company have just acquired and equipped for the manufacture of all kinds of electrical machinery, including a special line of alternating current apparatus, direct current machinery for incandescent lighting, power generators, railway motors, arc lighting apparatus, and a variety of accessories such as switchboards, measuring instruments, etc.



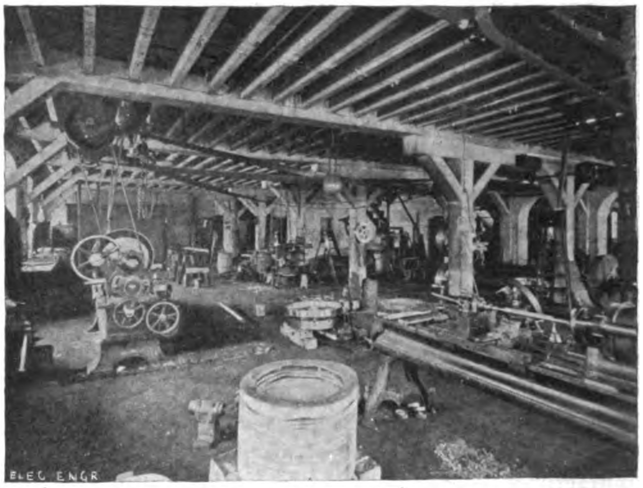
Heavy Planer Driven by Electric Motor.

II.

The new works, facing on American, Diamond and Bodine streets, Philadephia, are seven stories high with a frontage on Diamond street of 120 feet, and on Bodine street of 116 feet. The building is substantially built, with 30 inch walls and is one of the largest factory buildings in that section of the country.

Descending to the basement or first floor the visitor's eye first meets the power plant which consists of three 125 h. p. engines and one 25-h. p. engine. One of these drives two direct current generators, one alternator and an arc light machine. The direct current generators furnish power throughout the works, as all the departments are run with individual motors, no belts of any kind passing through the floors. Where a number of machine tools are grouped, a small countershaft is placed overhead, driven by an electric motor. The small 25-h. p. engine is used for lighting the office, etc., after 6 o'clock p. m., when the main plant is shut down. The two remaining engines are used for testing purposes and are so arranged that any one of them, or the combined power of the three, can be concentrated upon one generator, thus giving a total capacity of 400 h. p. There are in all four boilers of 125 h. p. each, one used for heating the building and the remaining three for power purposes.

On the same floor is the blacksmith shop where all the heavy machine work is done. There is also considerable heavy brass work done on this floor as some of the brass spiders and shields used in the 5,000 light alternators are turned up and finished in this department, extra large lathes and tools being required to handle these large diameters. On the same floor, one of the large planers, as will be seen, is run by an individual motor.

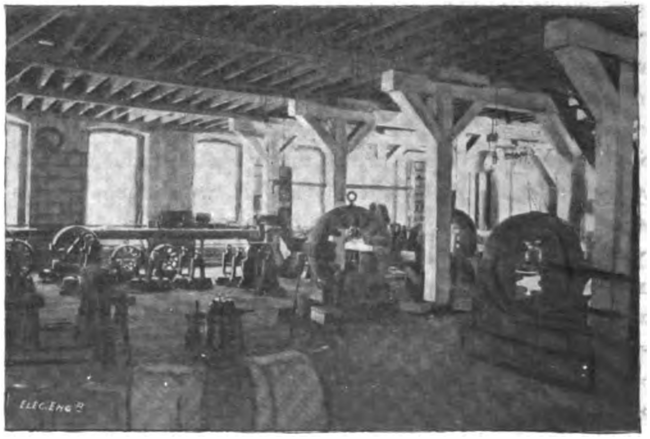


Heavy Machine Department in Basement.

On the second floor is the erecting, assembling and testing room where a number of both large and small direct current machines and alternators are in course of construction. The stock room is also on this floor. In the stamping department will be noticed a large stamping press where the armature discs are cut and stamped, and also insulated and assembled.

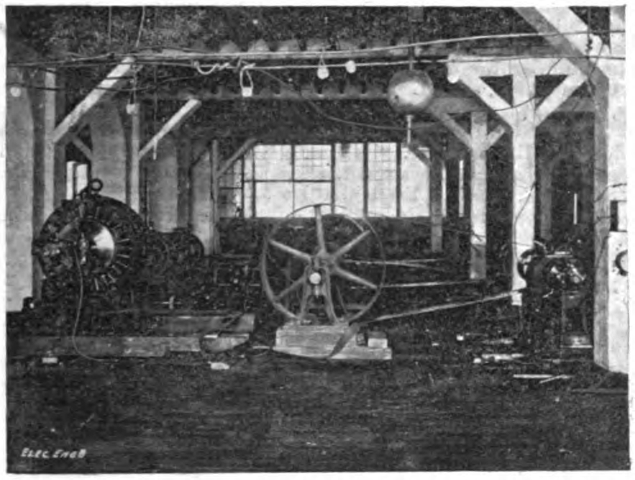
III.

The La Roche alternating armatures are of a novel and ingenious construction and are so arranged that any number of coils up to one half the total number may be burned out or affected from any cause, without interfering with the running of the machine at full load ; and in case of such an accident, repairs can be made in a very short time. A toothed armature is used for all alternators of 500 lights capacity or over, and a smooth armature for all machines under that size. They are of the laminated type, made of the best Norway iron, insulated with specially prepared paper. On the 2,600 light machine, the armature is bolted together with 27 bolts. The grooves of both armatures are of a new design and exceedingly shallow, insulated with asbestos and the best grade of mica, making them practically fire and water proof. No rectifiers or commutators of any kind are employed in the La Roche machine, but simply two collector rings ; the regulation is entirely automatic, no outside controller of any kind being required.



Assembling Department.

The armature which is mounted upon an extra heavy steel shaft ground to gauge, is absolutely iron-clad, and no wires show when it is completed. It will be noticed that the machine is so built that the frame or ring is cast in two separate parts so arranged that the top half can be lifted and any field coils removed and replaced. Another advantage claimed by the manufacturers is that it is not necessary to remove the armature or any portion of the machine to insert a new coil in the armature. The end of the armature is protected by a brass shield which is carefully insulated and where the leading in wires cut through they are insulated with micanite and hard rubber bushings. The collector rings are mounted upon an individual sleeve and arranged so that either one or both rings can be removed in a short time. All the La Roche machines are equipped with ball and socket, self-oiling bearings.



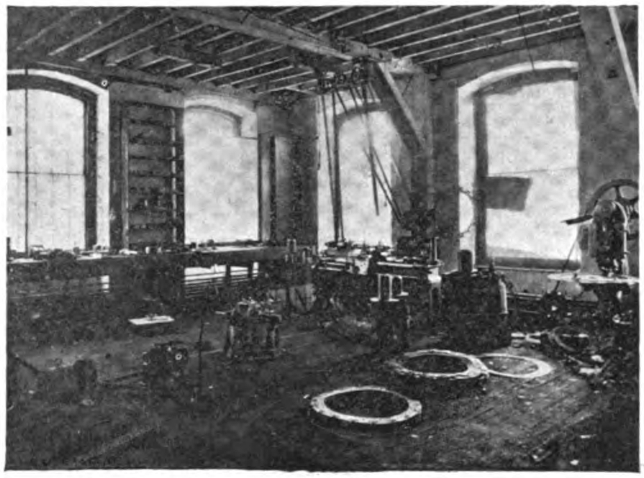
Testing Department.

Although the company have been more recently occupied with alternating machinery, they nevertheless continue to manufacture direct current apparatus, and are now making power generators ranging in sizes from 50 to 300 H. P. All generators of 100 H. P. and under are built on the motor bipolar type. The generators over 100 H. P. are made on the multipolar type with circular fields similar to their alternating machines. The La Roche direct current machine is entirely automatic, the method of regulation being new and different from the ordinary method of compounding. All the direct current machines have Gramme ring armatures, and the company from the very beginning designed machines with armatures greater in diameter than in length. It is evident that this construction admits of a machine of the same output being run at a much lower speed than when the armature is reduced in diameter and increased in length.

A Corner of the Stock Room.

IV.

On the third floor is the brass finishing room which is also well equipped with modern machinery. On this floor also is the armature and field winding department, where the armatures and fields of both direct and alternating apparatus are separately wound on frames or spools and slipped on the machines when completed. In this room there are smooth and toothed armatures in course of construction. In the usual method employed with both the fields and armatures, winding is begun at one end of the wire and carried out continuously, the other end being finally made to cross the convolutions in order to be brought out parallel with the other end; this subjects the crossing end to the maximum difference of potential on the entire coil and is a frequent cause of burn-outs and short circuits due to the inevitable vibration, and consequent damage to insulation, which takes place. In the method pursued by Mr. La Roche, the winding is begun in the middle of the wire, both ends being wound at the same time, and when the wire is finished, the two ends come out opposite each other at the centre of the coil without crossing any other convolution. This method brings the least insulation strain on the wire and the breaking or burning of one end does not require the entire re-winding of the coil.

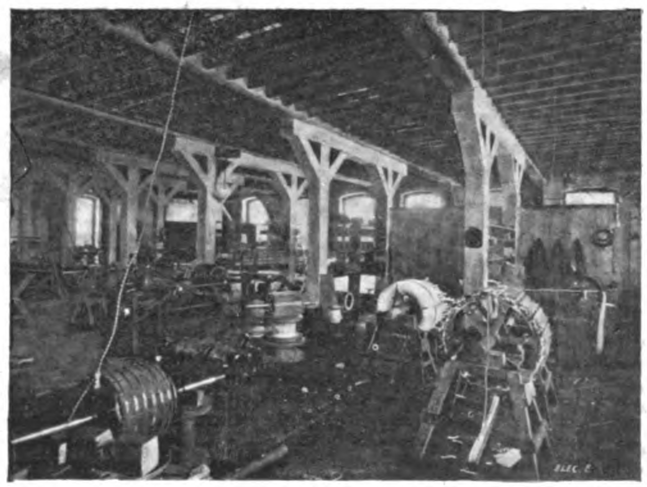


Stamping Department.

Recognizing the value of accurate and reliable indicating instruments in isolated as well as central station work, the La Roche company, almost from the beginning have built the indicating instruments with which their plants have been equipped. These consist of a voltmeter, potential indicator, ammeter-indicator and amperemeter. They are handsomely gotten up, enclosed in brass cases, having either back or surface connections, and lend a very neat appearance to the switchboard.

The fifth floor is used for a wood-working, pattern making and packing room, and the sixth is used for storage purposes. All the floors are connected by an elevator run by an electric motor.

The La Roche company have been running their works for the past six months day and night, working on large alternating machines, and have recently installed several 2,600 light machines and quite a number of 1,300 light alternators. Two of the latter

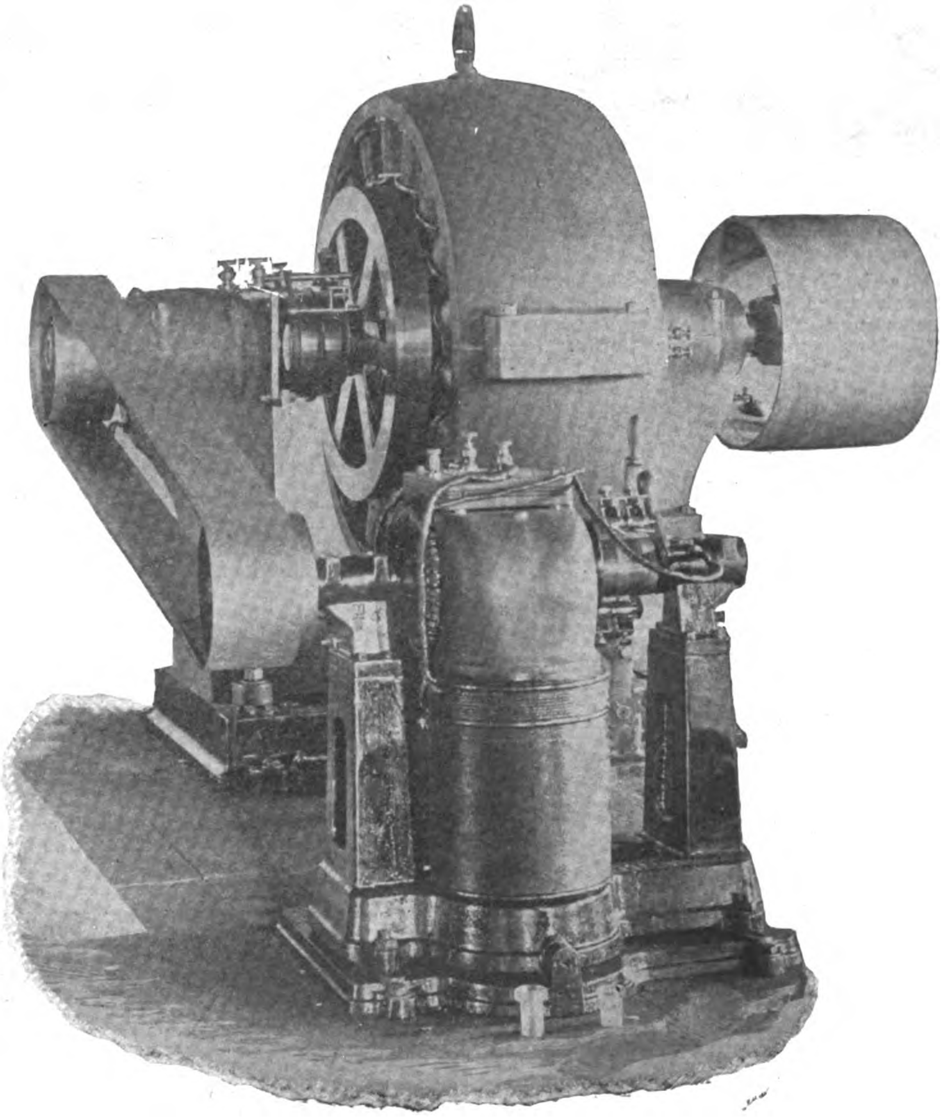


Armature Winding Department.

are now in the station of the Quincy Electric Light and Power Co., Quincy, Mass.

V.

The origin and history of a firm are frequently as interesting and instructive as the description of its products, and this is pre-eminently so in the case of the La Roche company. The moving spirit in the enterprise, Mr. F. A. La Roche, is a type of those who by dint of hard work and studious application compel success in spite of the heaviest odds. Born in 1859, Mr. La Roche at an early age exhibited an aptitude for mechanics that found an application in the building of small steam engines, mechanical toys, etc. At fourteen Mr. La Roche commenced a course of chemistry with Prof. Mathew, in New York, and three years later he removed to Philadelphia and finished a course of civil and electrical engineering under Prof. Beck.



THE LA ROCHE ALTERNATOR WITH EXCITER.

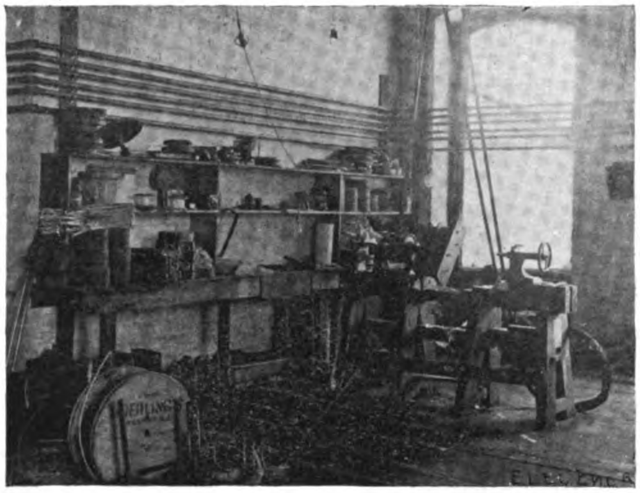
A recital of many of his boyish ideas and experiments would afford considerable amusement, but through them all would be seen that native genius which leads to success. One project in particular on which his youthful dreams of fortune were wrecked, centred in an attempt to build a motor with permanent magnets in which he used the current of several primary batteries to temporarily invert the poles of the magnets by sending around them a current opposed to their natural polarity. The experiment was a failure from an electrical point of view; nevertheless from each such failure he gleaned some valuable information that was stored for future use. Another effort that met with a fate similar to the last, was to combine the storage and gas batteries in the same cell. Mr. La Roche made an iron vessel with a tight-fitting lid and provided the interior of the cell with the elements and compartments for the gases evolved during charging. This battery actually gave three volts before it exploded and this was the consoling thought that repaid him for the disaster. The battery has already been illustrated in the ENGINEER.

Mr. La Roche's experience in the electrical business began about fourteen years ago, when he commenced making laboratory apparatus and afterwards constant current motors. He claims, indeed, to be the first to make a successful automatic cut-off, constant current motor. When Mr. Maxim came to this country and started to manufacture in Philadelphia what was known as the Maxim machine, Mr. La Roche, who was quite young at that time, brought a motor to him and asked him to test it on his circuit. Mr. Maxim answered that no motor could be made that would stand the pressure. He finally put it on the circuit but it heated to a considerable extent, though, after rewinding it was found to work nicely. From that time on Mr. La Roche made a specialty of building both constant current and constant potential motors and up to the present time there are several La Roche constant current motors on the Brush circuit in Philadelphia.

The La Roche Electric Works proper were started in a room 8 x 8 feet, with a small foot lathe and one mechanic,—Mr. La Roche himself. Business seemed to prosper with his small but earnest efforts and an addition was made in the shape of a boy. Business increasing with a strong demand for small dynamos, the whole of the second floor was then taken and about one year afterwards the third floor of the same building. Still finding it necessary to have more room, the building No. 116 N. Sixth street was rented and three floors used, and a short time after that the entire building was occupied. The business still continued to grow, new machinery was purchased from time to time and more men put on, until finally, that building also became too small for the demands and the one adjoining, No. 118, was rented and doors cut through and the company continued there for nearly three years.

The increasing operations of the concern then determined Mr. La Roche in incorporating the business into a stock company which subsequently purchased the property they now occupy at American and Diamond streets, which has been described above.

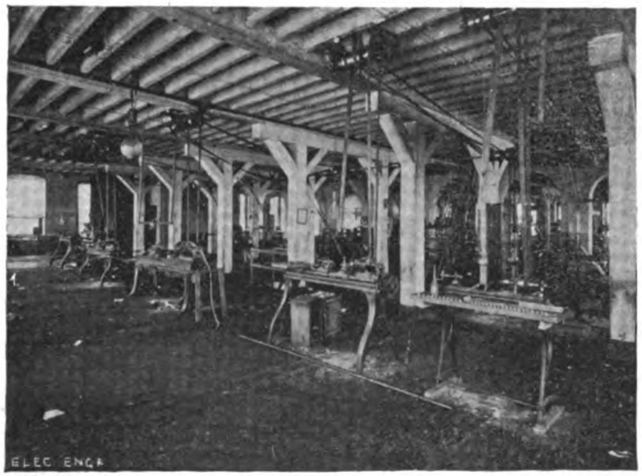
Mr. La Roche has for several years given special attention to alternating current machinery. The excellent alternating system of the company is the result of his labors, as likewise some five or six other systems that are now owned and operated by the company. The determined manner in which he takes hold of a problem generally insures its satisfactory solution. Nothing seems to daunt him, from the requirements of the most delicate instrument work to the building of a 10,000 light dynamo, and these, with everything between them as extremes, are manufactured under his direction.



Glimpse of The Field Magnet Winding Department.

VI.

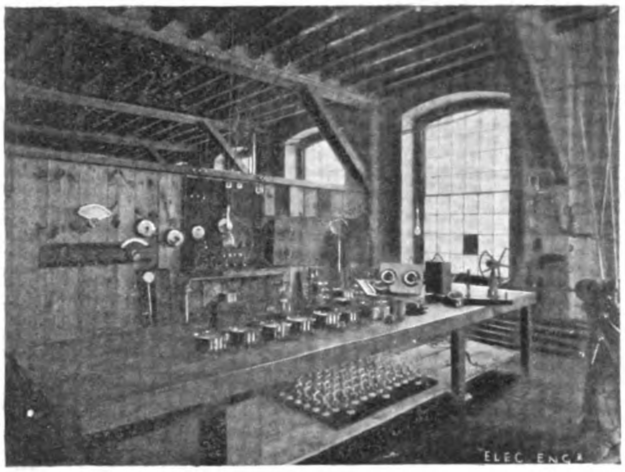
Of late years, Mr. La Roche has surrounded himself with such assistants as the rapidly growing business demanded. Among these is Mr. Frank J. Stevens, the secretary and treasurer of the company who was elected last November to the position he now holds and which he fills to the complete satisfaction of the Officers and Directors. Mr. Stevens is a graduate of the University of Pennsylvania where he took degrees in mechanical and electrical engineering. He was formerly a member of the firm of John S. Stevens & Sons in which he obtained his practical and financial training. His services have proved extremely valuable to the company who feel that they have made a wise selection.



Brass Finishing Department.

Mr. Geo. S. Loutey is the superintendent of construction and installation. He has been in the employ of the company about eight years, is esteemed by the officers for his faithfulness and loyalty, and is regarded as a permanent fixture.

Mr. Wm. G. Toplis, the chemist of the company, has been associated with Mr. La Roche for twelve years. He is known as a first-class chemist and has contributed a number of inventions to the Government.

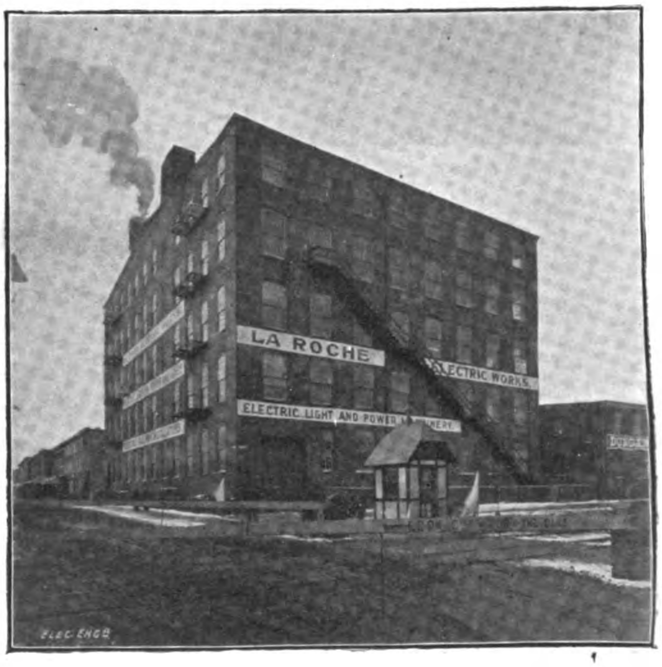


Calibrating and Instrument Department.

Mr. J. W. W. Cornman, a graduate of the Philadelphia Manual Training School has charge of the Instrument Department. He is well versed in the instrument business, having been formerly in the employ of Messrs. Queen & Co.

Mr. Geo. W. Bacon is a member of the engineering staff. He is a graduate of Cornell University having taken degrees in mechanical and electrical engineering and was formerly with the Wightman Motor Co., of Scranton, Pa.

Mr. Frank R. Ford, also a member of the engineering staff is a graduate of the University of Pennsylvania, and was formerly with the Short Electric Co., of Cleveland, O., having had charge of the Chicago office of that company. He now has charge of the railway department of the La Roche Electric Works.



The La Roche Electric Works.

Mr. Gurney F. Coleman who has had an extensive experience in the installation of isolated and central station plants is now associated with the company in that capacity and is well fitted for the position. Mr. Coleman is also a graduate of the University of Pennsylvania.

Mr. C. C. Miller, assistant superintendent of the works, was formerly with the Novelty Electric Co. He attends to the details of the manufacture of the apparatus under the direction of Mr. La Roche.

VII.

Besides its own competent home staff the company have secured the services of a number of able coadjutors in their agencies established in every section of the country. Thus, in New York their interests are well cared for by Mr. W. A. Vail. Mr. Vail began in the electrical field in 1879, with the Bell Telephone Company, of Maine. In the Spring of 1881 he took charge of the uptown construction of the Metropolitan Telephone & Telegraph Company, of New York, and filled nearly every intermediate position until 1887, when he was made general superintendant of that company. In 1880 he resigned to take the position of vice president and general manager of the Boston Heating Company, and remained there until the company wound up their affairs. In February, 1891, Mr. Vail began business as a dealer in electrical supplies which he carried on successfully. On January 15, 1894, he accepted the agency of the La Roche Electrical Works of Philadelphia for New York and New Jersey, with offices in the Electrical Exchange Building, No. 186 Liberty street, New York.

The La Roche Company also have an office in Chicago at No. 239 La Salle street, managed by Messrs. Hood & Osburn. Mr. Owen Ford represents their interests in St. Louis, Mo., Rialto Building; the Southern Brass & Iron Co., in Knoxville, Tenn.; the San Francisco Electric Co., in San Francisco, Cal.; and the Campbell Electrical Supply Co., in Boston, Mass.

F. A. La Roche.

REPRESENTATIVE MEMBERS OF THE STAFF; LA ROCHE ELECTRIC WORKS.

STEALING CURRENT IN NEW YORK.

Two men were arraigned recently in a New York court for stealing electric power, the case being the first of its kind in the city. Edward Gardner and his brother-in-law had charge of the exhibit of the Roulette Cycle Company of Coventry, Eng., at Madison Square Garden. Frank Martin, the electrician of the garden, observed that the wheels of a bicyle hanging above Gardner's booth were being turned at a rapid rate by some unseen power. On investigation he found that the electric light wires had been tapped, and were connected with a small electric motor, which kept the wheels in motion.

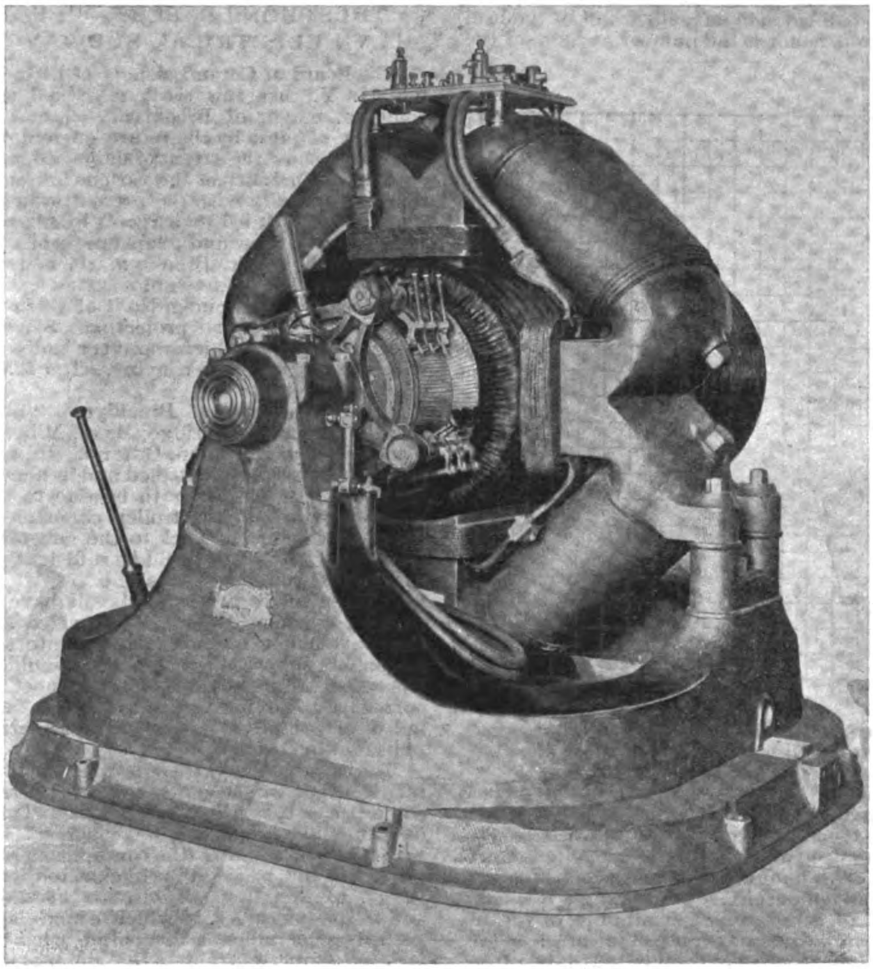
MR. W. A. GILES who for the past three years has carried on the business of mechanical engineering and equipment of steam plants, at Pittsburgh, Pa., has removed to New York where he is representing the Goubert Mfg. Co., at 32 Cortlandt street.

THE "STANDARD" MULTIPOLAR GENERATOR.

The very gratifying success which has attended the introduction of the arc light dynamo made by the Standard Electric Co., Chicago, led the company to believe that the principles involved in the construction of that machine might be successfully applied to the manufacture of other forms of generators, and working from this standpoint they devoted about a year to designing and perfecting a complete line of direct current as well as alternating current apparatus, including all the usual accessories, such as instruments, switches, transformers, etc.

We are enabled this week through the courtesy of Mr. C. E. Woods their electrical engineer, to give our readers an illustration and a brief description of their latest type of multipolar, direct current generator.

The machine is of a solid and substantial design, with large base insuring rigidity and freedom from vibration. The field has four consequent poles, the wrought iron cores being bolted between soft cast iron pole pieces. The two horizontal pole pieces have two lugs each and by them the field magnet frame is bolted to the base, a zinc distance piece being interposed at each side to prevent magnetic leakage to the bed plate.



THE "STANDARD" MULTIPOLAR GENERATOR.

The journal seats are bored in line with the armature bore, and the journal supports being turned in a lathe to a corresponding arc absolute alignment of the shaft with centre of field bore is assured. The journals are self-oiling, two loose rings being provided for carrying the oil from a reservoir to the shaft. The journals are self adjusting, being of the universal ball bearing type, allowing the armature shaft to have all necessary adjustment at all times. By removing a pedestal at either side of the machine the armature can be easily and quickly taken out for inspection or cleaning.

The armature is of the conventional Gramme ring type, but has several important modifications in its details, securing better insulation and absolute stability of the armature conductors. The soft iron armature rings are supported by a split gun metal spider.

The commutator shows several important improvements in its construction, no insulation except air being used between the segments, where the brushes come in contact with the commutator bars. The mechanical construction of the commutator is such as to enable any intelligent mechanic to renew any defective segments or even replace the entire commutator in a comparatively short time.

A neat and substantial switchboard of slate or marble is supported over the two upper fields and incidentally quite an ingenious use is made of the well known property of a magnet to repel an arc. The two main line fuses are located almost directly over the ends of the upper fields and the result is that in case a fuse is blown from any cause, all dangerous arcing is prevented, owing to the repelling action of the pole piece underneath the switchboard.

The brush holders are of a novel and neat design, short blocks of carbon being clamped firmly between two metal jaws, thereby giving a minimum resistance to the brush proper and securing perfect contact with the commutator. In the 125 H. P. machine, five brushes, each 1¼ inches wide, are used on each brush holder stud, the current allowed in the commutator being as low as 200 amperes per square inch. The two sets of brushes of the same polarity are connected together by two double connecting bars, no cross connections in the armature itself being used.

The base is arranged so that a pawl and ratchet may be applied to either end, and in case it is desired to reverse the direction of rotation of the armature, no change in the connections is required, the simple reversing of the brushes and bringing them into the opposite neutral plane, respectively, being all that is necessary.

The more important data of a 100 K. W. 110 volt machine are as follows :

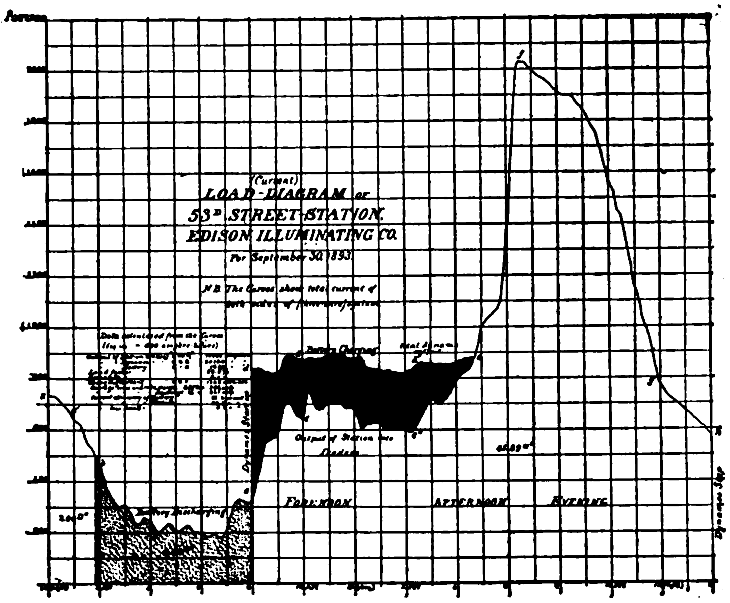
Output	100 K. W.
Speed	425 rev. p. min.
Diameter of armature, over all	29 inches
Length " " " "	18.5 "
Diameter of commutator	18 "
Number of segments in commutator	144
Magnetism in pole pieces per square inch (B)	46,000
" " armature per square inch (B)	60,000
Current density in armature conductors	2,000 amp. per sq. in.
Resistance of field coils	18 ohms.
Shipping weight	14,000 lbs.

The Standard Electric Company will soon have a complete line of these machines on the market of 110, 220 or 500 volts. Several of the machines are already in use in Chicago and giving the best of satisfaction.

STORAGE BATTERIES FOR CENTRAL STATIONS, POWER PLANTS AND LARGE ISOLATED INSTALLATIONS.

The Consolidated Electric Storage Battery Company, of Philadelphia have recently issued a pamphlet, No. 8 of its series, from which may be gathered some highly interesting data on storage battery practice. Whatever differences of opinion may exist as to the universal use of storage batteries in electrical industries, their advantages as an auxiliary in isolated and central station lighting and in power stations are universally conceded. These advantages have been very largely embraced in Europe, where we find something over 175 central and sub-stations equipped with storage batteries, and a much larger number of isolated plants; while in this country there are but two central stations equipped with storage batteries and less than one hundred isolated plants. The monthly sales of storage batteries of one factory in in Germany amount to $125,000; an English storage battery company approximates this figure, and Paris with its thirty storage battery central and sub-stations, creates a considerable demand.

The first requisite in determining whether a battery can be advantageously introduced in any given central station, and if so what its size or capacity shall be, is to have diagrams of the load curves. The next important factor is the number and size of the units employed at the station. From this data may be determined the load factor, and then it is easy to calculate the size of the battery required to give the most economical operating results. Once the size of the battery determined, we can calculate the saving effected by dispensing with a night shift; by diminishing the consumption of coal for a given output; by operating a few large units of one size, instead of a number of small units of various sizes; by operating each unit at its maximum efficiency; and by the additional revenues from increase of total output taken from the battery at the time of maximum load.



LOAD DIAGRAM OF 53D STREET, EDISON STORAGE BATTERY STATION, NEW YORK.

As the item of labor in small stations is frequently as high as twenty-five per cent. of the operating expenses the saving effected by dispensing with a night shift is not inconsiderable. By operating exclusively large units there is also a material saving effected both in labor and the much heavier efficiencies of large over small units. Again, as the coal bill is one of the largest items of expense, amounting in some cases to fifty per cent. and over of the total operating expenses, any saving effected in this item is of paramount importance, and is reflected at once in the decrease in operating expenses.

The question of mechanical efficiency with varying loads has not been as carefully studied with each type of engine as its importance deserves, but Prof. W. Cawthorne Unwin, F. R. S., has shown that the decrease of mechanical efficiency for light loads has a serious effect on the economy of working with a variable load and that with a load varying from one hundred to twenty-five per cent., the efficiency decreases from eighty-five to forty per cent.

While it is impossible to say in a general way what the exact saving would be from the introduction of a battery of sufficient size to permit of the operation of all the units at maximum load (since the load is not the same in any two stations), the results prove that in central stations equipped with storage batteries the operating expenses are diminished as much as thirty per cent.

In addition to the saving effected in operating expenses the use of a battery may be made to yield additional revenues in proportion to the amount of current supplied to the circuit over and above what could be supplied by the direct system, at the time of maximum load, except by increasing the size of the power plant. Central station lighting is one of the most important fields of usefulness of the storage battery and one which has hardly yet been touched upon in this country. The same arguments apply with increased force to its application in a power house for electric traction. Here the variation in the load is between such wide limits and of such a sudden character as to render it impossible to operate the power plant on anything like an economical basis.

In all such cases by the introduction of a sufficiently large battery the load curve, instead of resembling a stroke of lightning as it does at present, could be perfectly equalized, as shown in the accompanying diagram, enabling the power plant to operate at full load and maximum efficiency.

CORROSION OF WATER PIPES, GAS PIPES AND TELEPHONE CABLES.—REPORT OF THE BROOKLYN ELECTRICAL SUBWAY COMMISSIONERS.

The Board of Commissioners of Electrical Subways of Brooklyn, N. Y., has this week presented to the Hon. Charles A. Schieren, mayor of Brooklyn, a special report on the subject of corrosion of pipes by the return current of the street railway systems. To show the extent of damage done to gas and water pipes, etc., by the inability of the various lines to control the return current of electricity with the present system in vogue, the commissioners accompanied their report by nine different photographs of specimens of pipe and telephone cables removed by them from various localities in Brooklyn. It had been claimed by various electricians that pitch would act as an insulator in covering telephone cables. Specimen No. 1 of this report shows conclusively that pitch proved no protection. Specimen No. 8 illustrates a piece of iron pipe which was very badly corroded and perforated within thirty days after laying. The following is an abstract of the special report:

"The experience of Brooklyn is not notably different from that of Boston, Cambridge, Mass., Milwaukee, Columbus, O., Indianapolis and Hamilton, Ontario. In each of these cities similar corrosions have been detected and in none is there any doubt as to the cause. It is known to be due to the imperfections of the means provided by the trolley companies for the conveyance of the electrical current back to the generator. It was at first supposed that the rails would be sufficient, but the current declines to take that route exclusively.

"The remedy of the evil will have been applied when the trolley companies shall have provided an adequate route for the electric current now discharged into the rails. It was at first reasonably supposed that the rails would afford a sufficient path. Upon the failure of this plan, a copper connection, to carry the current by the joint, was tried. In most cases this expedient failed of complete success, except when the copper bond had unusual dimensions."

The commissioners then devote about two and one-half pages of their report to an account of some experiments relating to proper connections between the rails, taken from THE ELECTRICAL ENGINEER, and with which the readers of this journal are already familiar. Continuing, the commissioners say:

"It should be said in reference to this second method (merely the connection by metal circuits of the water mains, gas pipes and telephone cables, to which some electricity will always pass, with the generators at the points where there is the least resistance to return currents), that in making connections with the underground systems of pipes and cables, the points of such connections would require frequent examination. A copper connection with an iron pipe underground would not long remain a reliable conductor, unless special care and watchfulness are given to it.

"A better way to insure the conduction of the current is doubtless to make the car rail continuous by welding. This method will be employed on the new trolley line soon to be built in the southern part of the city.

"The most complete solution of the problem is afforded by the double trolley by which the return current is provided for by an overhead wire similar to the one for outgoing current. But it is to be hoped that it will not be necessary to resort to this method."

Some notes of experiments obtained through the kindness of Mr. I. H. Farnham, Electrician of the New England Telephone Co., and relating to the early experience in Boston, are here given.

When the action of the current was first noticed, the experiment of grounding the cable to lead plates buried in manholes, was tried on quite an extensive scale, but was soon abandoned as being impracticable. The quantity of electricity to be dealt with was so enormous that the buried plates offered no appreciable protection to the cables. If such a system were feasible, the expense for the constant renewal of plates would be very large.

The severity of the action to a certain limited extent, was reduced by so arranging the direction of the current used for the street railways, as to make it pass out over the trolley wires, and back through the ground. In this way the direction of the current would be quite generally from the earth to the cables, thus diminishing in certain places, the corrosive action. This method would not be a complete protection from the corrosive action, as there would be places where the current would still flow from the cables. Even though the current is uniformly to the earth from the cables, there is the possibility of an action caused by alkaline substances formed about a cable, due to decomposition by the current from the street cars of the soluble salts contained in the surrounding earth. There alkaline substances are capable, under certain conditions of dissolving the lead, when the currents are shut off or much reduced, as would be the case at night.

As there has been some misunderstanding in regard to the potential measurements made in connection with the numerous corrosion investigations, it should, perhaps, be impressed upon those who are about to carry on similar investigations, that the potential measurements between the cables or pipes and the material surrounding them, should, in the majority of cases, only be looked upon as incating the direction in which the current tends to flow.

To say that the pipes and cables are even practically safe from corrosion when the measurements are below a specified figure, would be extremely misleading. The measurements are, in a certain sense, like the measurements which might be made in an electrolytic cell, between one of the electrodes and various portions of the electrolyte, so that it is possible to conceive of almost zero potentials in the immediate vicinity of the most violent electrolytic corrosive actions.

The fact should be closely borne in mind that whenever we have a current passing from an easily oxidizable metal to the liquid, such as would be encountered in the earth, corrosion is bound to occur.

A large number of electrolytic experiments have been carried out, showing the extremely low potentials (measurements between the electrodes) at which corrosion is found to take place. In many cases iron and lead were destroped, under the conditions encountered in the underground systems, at potentials considerably under .5 volt.

"The conclusions fairly drawn from these notes and from our own experience is that considerable injury is being done to underground pipes and cables, and that it will continue along the lines of the trolley roads (except where the elevated railway extends above them) until better methods of returning the current to the generator are put in practice. The electricians of the several trolley roads are fully aware of the situation and have speedily applied means of prevention in localities where the corrosion had been detected. But it is doubtful if the method of final cure of the difficulty has yet passed the experimental stage." The report is signed by Prof. Geo. W. Plympton and Fred R. Lee, commissioners.

PERSONAL.

Mr. John J. Moore, formerly general manager of the East River Electric Light Co., in New York and identified with numerous undertakings of the General Electric Co. in the past, has been appointed general manager of the Narragansett Electric Light Co., of Providence, R. I. Mr. Marsden J. Perry, the vice-president of the company remains in control as heretofore.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the Meeting of the Institute, held Wednesday, Feb. 21, the two following papers were read: "How Shall We Operate an Electric Railway, 100 Miles from the Power Station," by H. Ward Leonard; and "Concerning a Change of Policy in the Administration of the Patent Office," by Philip Mauro.

The Report of the Committee on Revision of Election Rule was presented, but action on the adoption of the rule was deferred so as to permit the question to be decided by the Annual Meeting.

The following gentlemen were transferred from associate to full membership:—Byron C. Wolverton, Elmira, N. Y.; C. Reginald Van Trump, Wilmington, Del.; Wm. D. Sargent, Brooklyn, N. Y.; Clarence E. Gifford, Buffalo, N. Y.; Jesse R. Lovejoy, Boston, Mass.

The following were elected to associate membership:—Clifford D. Babcock, New York City; William S. Barstow, Brooklyn, N. Y.; Albert L. Clough, Manchester, N. H.; James W. Crosby, New York City; George Forbes, London, England; Arthur Frantzen, Chicago, Ill.; Edward M. Gerry, Newark, N. J.; Charles Gesseaume, Newark, N. J.; Harold Harrison, Montclair, N. J.; E. Randolph Hix, New York City; James A. Lighthite, San Francisco, Cal.; H. H. Morehouse, Quezaltenango, Guatemala, C. A.; Chas. Edwin Potts, Brooklyn, N. Y.; Albert E. Richardson, London, Eng.; Chas. F. Rittenhouse, New York City; S. D. Snook, Brooklyn, N. Y.; E. W. Trafford, Richmond, Va.; Augustus Treadwell, Jr., Brooklyn, N. Y.; George E. Wendle, Bethlehem, Pa.

LETTERS TO THE EDITOR.

PAYING STATIONS.

In your issue of the Feb. 14, you refer to the paper read by the writer at the recent meeting of the Northwestern Electrical Association, and claim that my assertion that it is the direct current stations which are paying the dividends is founded merely upon "belief" and not on fact, and further, state that dogmatism has no place in science or business.

If you had read the first part of my paper (which you failed to publish), you would have seen that I clearly stated the advantages of the alternating system for certain work, confining my advocacy of the direct current system to average towns of 30,000 inhabitants or less.

To show how far my arguments were founded on fact, I beg to submit the following statement as to the condition of the electric lighting industry in the State of Wisconsin, where the paper was read:

In Wisconsin there is not a single alternating current central which is paying a satisfactory dividend on the money invested, with possibly two exceptions. In the same State nearly every direct current station is paying handsomely, some as high as 17 per cent. per annum.

A distinguished electrical engineer and member of the jury at the World's Fair, stated at a former meeting of the Northwestern Association that he had tested alternating stations in which 60 per cent. of the current is lost to the company; a similar experience is not uncommon to other members of the profession. This is not an argument *per se* against the alternating system, but goes far to prove that the average country electrician cannot get the best results out of his apparatus.

The stock, and almost only, argument against the direct current system has been the high cost of copper; at present prices for that metal, this argument has lost its force. A five-wire system is now cheaper in 90 per cent. of the estimates made than the alternating.

For an example of pure "dogmatism" in electrical matters, I would refer you to the February number of the *Engineering Magazine*, an article in which states that the direct current system is totally out of the question for small towns! This author sees me and goes one better with a vengeance.

W. N. Stewart.

Chicago, Feb. 20, 1894.

STORAGE BATTERY LITIGATION.

I notice in your last issue a communication from Mr. W. W. Gibbs, President of the Electric Storage Battery Co., in which, after serving up the old story of Profs. Chandler and Barker as to the chloride accumulator not being an infringement of the Brush patents, he goes out of his way, in tradesmanlike style, to decry the wares of his rival. He tries to make us believe that this attack is evoked because my Company has seen fit to exercise its legal right to sue him for infringement of our patents. This is the only offence of which we are guilty. We disclaim Mr. Gibbs' charge of the circulation of any objectionable matter in relation to this battery, except that in one or two instances we have sent to purchasers the usual notice of infringement, which, in a measure, we are bound to do, under the rulings of the courts, if we expect to invoke the aid of the law in securing damages hereafter.

I think Mr. Editor, that the over-confidence which Mr. Gibbs assumes is calculated to give all the less weight to his statements. You will perceive that this is the more so when I tell you that the Company owning the chloride battery in France, the "Société Anomyme pour le Travail Electrique des Métaux," was sued last year by the company owning the French Faure patent, and that Baron Rothschild, who is largely interested in the Chloride Battery Co., purchased peace at the expense, as I am informed, of several hundred thousand dollars. The French Faure patent is the equivalent of the American patent No. 252,002, and has only *one year* from next October to run. It was decided by our courts here that the Faure patent and the Brush patent were for the same invention. The same decision was rendered by the Patent Office, in the interference between Brush and Faure. The Faure patent was also sustained by the highest courts in Germany, in a decision much more far-reaching than any of the American decisions sustaining the Brush or Faure patents here.

In the light of these facts, it can hardly be contended that Mr. Gibbs is candid in proclaiming to the public that he does "not infringe the Brush or any other patents in the slightest degree." Profs. Chandler and Barker, under whose banner he hopes to win the coming battle, were also expert witnesses in the attempt to break down the Brush and Faure inventions in former suits, and they swore with as much zeal and vehemence in those former suits that the Brush-Faure patents were invalid, etc. It is fair to presume, in the light of history, that their affidavit which Mr. Gibbs publishes, would hardly justify a man in purchasing the chloride battery, or the public in believing them. The fact is, we must assume that Mr. Gibbs is desperate, for he writes like a desperate man.

WM. BRACKEN,
President, *Consolidated Electric Storage Co.*
NEW YORK, Feb. 23, 1894.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEBRUARY 13, 1894.

Alarms and Signals :—

Electrical Signal Apparatus, G. W. Hey, Syracuse, N. Y., 514,461. Filed April 22, 1892.

A signal designed for telephone or telegraph service employing a line conductor and actuating mechanism at each station connected to the line conductor and acting to bring the terminals of the circuit closers at one station into contact with each other and simultaneously returning to their normal position the normally separated terminals of the circuit closers at the other station.

Electrical Signal Apparatus, G. W. Hey, Syracuse, N. Y., 514,462. Filed May 9, 1892.

Similar to No. 514,461.

Electrical Annunciator, C. F. Scattergood, Albany, N. Y., 514,501. Filed Nov. 3, 1893.

An automatic electric target signal.

Electric Railway Crossing Signal, M. J. O'Sullivan, Baltimore, Md., 514,566. Filed May 22, 1893.

Electric Annunciator, I. E. Rickey, Oakland, Cal., 514,686. Filed May 10, 1893.

Relates especially to a resetting device for drop annunciators.

Electric Alarm for Pressure Gauges, W. H. Bradt, Troy, N. Y., 514,697. Filed Nov. 22, 1893.

Electric Alarm, S. T. Sanders, Granite, Montana, 514,775. Filed July 29, 1893.

An alarm for mine elevator shafts.

Conductors, Conduits, and Insulators :—

Electrical Conductor, D. B. Hayward, Easton, Md., 514,460. Filed July 21, 1893.

Claim 2 follows:

An electrical conductor formed of twisted or woven graphite coated asbestos fibre.

Insulating Joint, E. F. Gennert, Brooklyn, N. Y., 514,822. Filed Aug. 10, 1893.

Electric Cable, T. Guilleaume, Cologne, Germany, 514,849. Filed Mch. 27, 1893.

Consists of a crimped cylinder of non-conducting material having helical grooves in which are bare conductors.

Distribution :—

Electrical Transmission of Power, C. S. Bradley, Yonkers, N. Y., 514,586. Filed June 28, 1890.

Employs a continuous current generator, a phasing device electrically connected therewith for converting the current into alternating currents of differential phase, and a motor the field magnet of which is charged by a continuous current and the armature by the alternating currents.

Dynamos and Motors :—

Current Regulator for Dynamo Electric Machines, C. E. Scribner. Chicago, Ill., 514,504. Filed Dec. 10, 1888.

Consists of an electro-magnet included in the main circuit, a low resistance shunt around the electro-magnet, a rod operated by the magnet and controlling the movement of the brushes.

Influence Machine, H. F. Waite, New York, 514,524. Filed Oct. 28, 1893.

Armature Connection for Dynamos, O. Dufault, Spencer, Mass., 514,817. Filed Oct. 27, 1893.

A connector for commutator bars consisting of an L shaped piece of metal furnished with a dowel formed of the end of the lead, and with a projection for retaining the binding cord.

Galvanic and Thermo-Electric Batteries :—

Electric Battery Cell, P. C. Burns, Peru, Ind., 514,845. Filed June 12, 1893.

Claim 1 follows :—

In an electric battery cell, a carbon element having grooves or depressions in which are plugs or pencils of insulating material projecting beyond the surface of the said carbon element.

Lamps and Appurtenances :—

Electric Arc Lamp, C. E. Scribner & E. P. Warner, Chicago, Ill., 514,505. Filed May 27, 1890.

Has for its object to automatically separate the carbons when the current passes and to maintain a uniform arc.

Electric Arc Lamp, C. E. Scribner, Chicago, Ill., 514,506. Filed Aug. 1, 1891.

Has for its object to provide circuits whereby arc lamps may be burned in groups; the members of each group burning separately, one after the other.

Electric Arc Lamp, J. E. Woolverton, New York, 514,583. Filed Sept. 22, 1892.

Claim 1 follows :

In an arc lamp the combination of a pair of converging rods, one at least of which is an arcing electrode, and a corresponding arcing electrode, with means for equalizing the feed of the pair of rods comprising a pair of lazy tongs mechanically connected therewith.

Incandescent Electric Lamp, G. H. W. Timbrell and J. C. Fyfe, Denver, Col., 514,789. Filed Sept. 18, 1891.

Employs a reflecting cylinder within the lamp about which the incandescent filament is helically wound.

Measurement :—

Apparatus for Testing the Resistance of Conductors of Electricity, E. G. Willyoung, Philadelphia, Pa., 514,580. Filed June 26, 1893.

Employs conductors constituting a multiple arc circuit one of whose branches comprises two resistances and means for supporting a test piece in series between them, and the other of whose branches comprises also two resistances ; and means for determining the point at which the potential of the branch containing the test piece is the same as that of the other branch at the junction of its two resistances.

Electrical Measuring Instrument, E. G. Willyoung, Philadelphia, Pa., 514,581. Filed Oct. 13, 1893.

Relates to details in the construction of quadrant electrometers.

Electrical Measuring Instrument, M. M. Garver and E G. Willyoung, Philadelphia, Pa., 514,593. Filed Oct. 18, 1893.

Similar to No. 514,582.

Electrical Measuring Instrument, E. G. Willyoung and M. M. Garver, Philadelphia, Pa., 514,582. Filed Oct. 18, 1893.

A hot wire measuring instrument on the Cardew principle employing a plurality of compensating wires, each substantially identical with the working wire. See page 194 this issue.

Miscellaneous :—

Electrical Firearm, J. L. McCullough, Brooklyn, N. Y., 514,491. Filed Apl. 7, 1893.

Garment Hook, R. Ahlers, Brooklyn, N. Y., 514,584. Filed Dec. 9, 1893.

An electrical hat and coat rack adapted to sound an alarm upon the unauthorized removal of any of its contents.

Electric Pendulum Clock, H. Campiche, Geneva, Switzerland, 514,641. Filed July 28, 1893.

Cigar-Tip Cutter and Lighter, W. E. Duthie, Indianapolis, Ind., 514,647. Filed Dec. 8, 1893.

Electric Cigar Lighter, A. J. Graydon, Indianapolis, Ind., 514,651. Filed March 6, 1893.

Electrolytic Cell, E. A. Le Sueur, Ottawa, Can., 514,681. Filed April 15, 1893.

Apparatus for Periodically Completing and Interrupting Electric Circuits, E. L. Berry and F. Harrison, London, Eng., 514,746. Filed Oct. 6, 1893.

Electric Lock, R. V. Cheatham, Louisville, Ky., 514,813. Filed Feb. 7, 1893.

Railways and Appliances :—

Electric Railway, P. W. Leffler, Minneapolis, Minn., 514,561. Filed May 13, 1893.

Claim 1 follows :

The combination with a car, or other traveling body, of field magnets in the line of travel, a non-rotating armature on the car, electric connections for the field and armature magnets, and an automatic rotary pole changer carried by the car, located in the connections to the armature magnets and operated by the field magnets.

Bond Wire for Electric Conductors, A. Hoffman & J. Brogan. Milwaukee, Wis., 514,714. Filed July 5, 1893.

Electric Railway System, P. W. Leffler, Minneapolis, Minn., 514,718. Filed Nov. 22, 1892.

Similar to No. 514,561.

Trolley, J. A. Williams, Altoona, Pa., 514,801. Filed Oct. 7, 1893.

Employs removable shaft blocks.

Electric Railway Conduit, R. I. Hampton, Athens, Ga., 514,837. Filed May 25, 1893.

Claim 7 follows :

An electric conduit, composed of a trolley rail chamber, a drain-way below the trolley rail chamber, and a cable-way located at the side of the trolley rail and provided with removable rack bars superimposed transversely in the cable-way to support and hold apart the cables.

Electrically Operated Street Indicator for Cars, H. C. Barker, St. Louis, Mo., 514,878. Filed June 28, 1893.

Switches and Cut-Outs :—

Cut-Out, H. Lemp, Lynn, Mass., 514,480. Filed Oct. 5, 1888.

Provides means whereby a lamp may be automatically substituted for one that has gone out where the lamps are arranged in series.

Telephones and Apparatus :—

Telephone, C. T. Bloomer, New York, 514,695. Filed May 9, 1893.

Claim 1 follows :—

In a transmitter, the combination of a diaphragm, a conducting fluid included in the circuit of the transmitter, a flexed flexible strip mechanically connected at one end with the diaphragm, suitably supported at its other end and immersed in said fluid.

Telephone Signaling System, W. Gillette, New York, 514,823. Filed July 13, 1893.

Employs a main circuit for holding the alarm out of action, a local circuit for the alarm, a circuit breaker for disconnecting the main circuit from the alarm and leaving the local circuit free to actuate the alarm.

NALDER BROS. & CO., OF LONDON.

We have received the following notification from the firm of Nalder Bros. & Co., London, electrical engineers and manufacturers of electrical and scientific instruments :—

> Owing to the numerous inquiries we have had recently as to whether we have changed the constitution and address of our firm, we feel it incumbent on us to state that there has been no change whatever, and that the partners F. H. Nalder, H. Nalder, C. W. S. Crawley and A. Soames, who have conducted the business during the last six years, still carry it on as Nalder Bros. & Co., and that our sole place of business is at 16 Red Lion Street, Clerkenwell, London, E. C. as heretofore.

WAKEFIELD ELECTRICAL ENGINEERING CO.

THE above company, Room 781 Reading Terminal, Philadelphia, Pa., have secured the contract for a seven mile extension of the Lehigh Traction Co., Hazelton, Pa. The work will be in the charge of Mr. A. W. Gilbert, the constructing engineer for the Wakefield Co. The road is to be built in a very substantial manner, and graded according to steam road practice. It will include several large trestles.

MONTCLAIR, N. J.—Application for an incandescent street and commercial lighting franchise was made to the Township Committee of Montclair. N. J., on February 19, by Paul Wilcox and other local capitalists. From 500 to 800 incandescent lamps would be required, according to street milage and candle power. Mr. M. N. Baker is chairman of the Street Lighting Committee.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

CROCKER-WHEELER STANDARD MULTIPOLAR MACHINES.

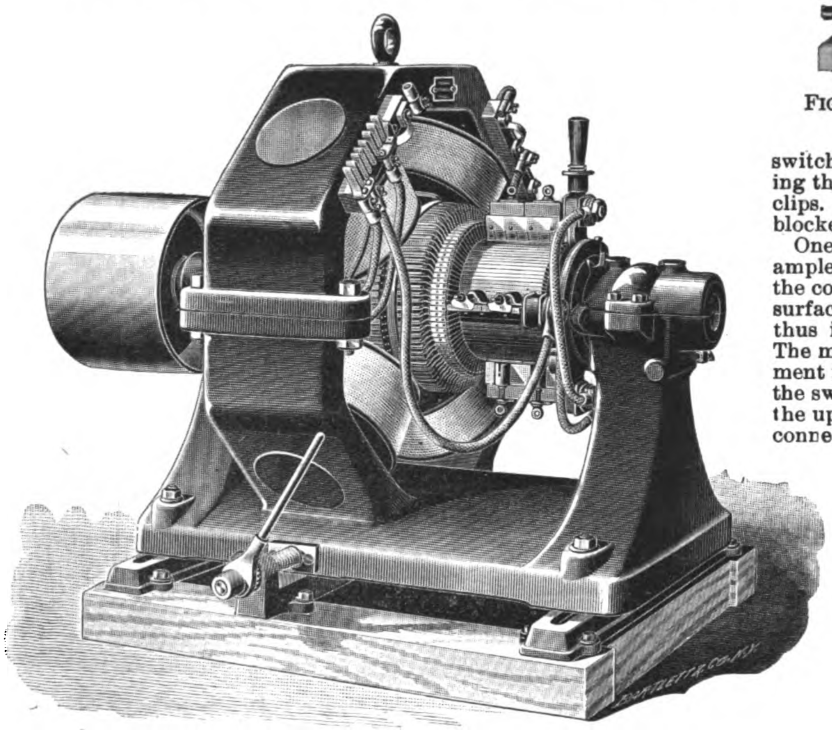
Since moving to their new works at Ampere, N. J., the Crocker-Wheeler Company have been very busy perfecting a line of larger sizes of dynamos and motors, of the type illustrated in the accompanying engraving, Fig. 1. The detail of these motors and dynamos represents the work of their entire engineering staff during the past year. As will be readily seen, care has been taken to produce an artistic design, a solidity of construction, and a close adjustment of proportions electrically within the machine.

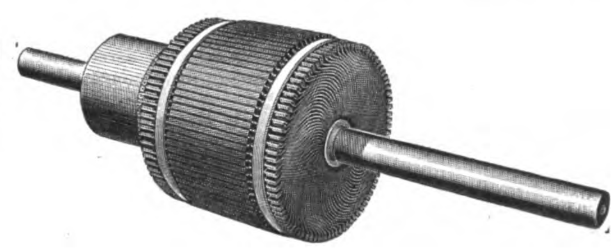
In the multipolar type illustrated, the steel magnets are turned to gauge and set into the yoke, the outer end of the holes for the fields being covered by a thin circular plate. The pillow block standards are cast in one piece with the base; the armature is accessible by removing the caps of the bearings and the upper half of the magnet frame, thus admitting of the armature's being lifted vertically out of the bearings when the upper half of the magnet frame is thus removed. The rocker arm is made in halves, held together by wing nuts, and travels upon a grooved ring attached to the pillow block standard and slotted, the grooved ring being cut away through the upper side, wide enough to permit the shaft to be lifted out. No solder is used in any part of these machines, and besides being built to stand 25 per cent. overload without undue heating, they will stand an altogether unusual degree of heating without injury.

The multipolar types above 25 H. P. (20 K. W.) for 110 volts, have armature conductors of rectangular copper bars riveted together by means of strip copper end connectors in place of the ordinary wire windings, as shown in Fig. 2. The armatures thus "wound" although for multipolar machines, have but two circuits and may therefore be operated with one set of brushes instead of two sets, because of the novel cross-connections with the armature. The common practice in multipolar armature winding heretofore employed, renders one portion of the armature liable to short circuit the other portions if there is any inequality in the strength of the fields. This construction is an improved form of that formally built by the Standard Electric Company, of St. Johnsbury, Vermont, of whom the Crocker-Wheeler Company are the successors in this line. This form of armature is the invention of Mr. C. S. Bradley, and was the prototype of the bar wound armatures now commonly made in large sizes, such as for railway generators, etc.

The new standard machines being brought out by the Crocker-Wheeler Company are, as a matter of course, of high efficiency, but what is more important is the fact that the necessary losses are evenly distributed in the various parts of the machine, so that the heat produced by these losses may be evenly distributed, and thus permit the machines to stand the greatest abuse without any one part suffering in excess. This point of distribution of the efficiency losses seems to be the direction in which to look for improvement, and is a matter about which engineers of the company are very wide awake.

For the equipment of the modern industrial power plants this higher class of apparatus is particularly adapted. One plant furnished by the Crocker-Wheeler Company already amounts to about 500 H. P. in motors alone, to which large additions are being frequently made.

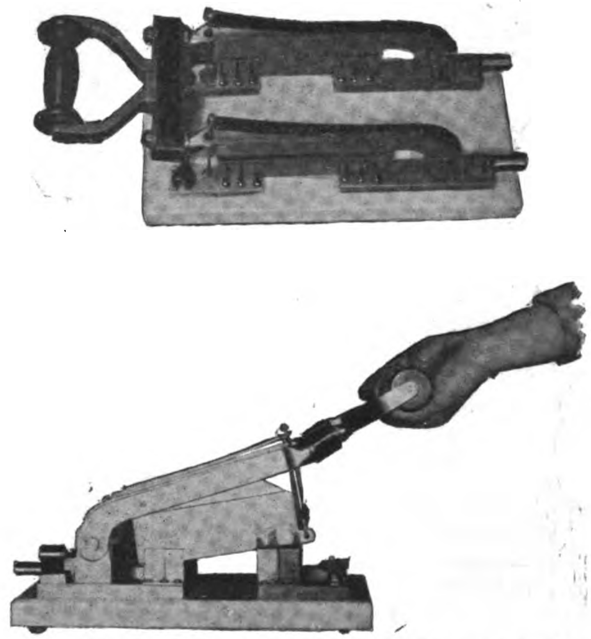




FIGS. 1 AND 2.—THE CROCKER-WHEELER STANDARD MULTIPOLAR MACHINE AND ARMATURE.

CENTRAL ELECTRIC NEW MAIN LINE SWITCH.

One of the latest productions of the Central Electric Co., Chicago, is their double pole, main line station switch, illustrated in the accompanying engravings. It has several points of merit, well worthy the attention of those interested. Fig. 1 shows the switch closed and Fig. 2 shows the switch at the moment of breaking the circuit, the blades just being at the point of leaving the clips. For the purpose of illustration, the blades have been blocked, showing the "quick break" springs under tension.



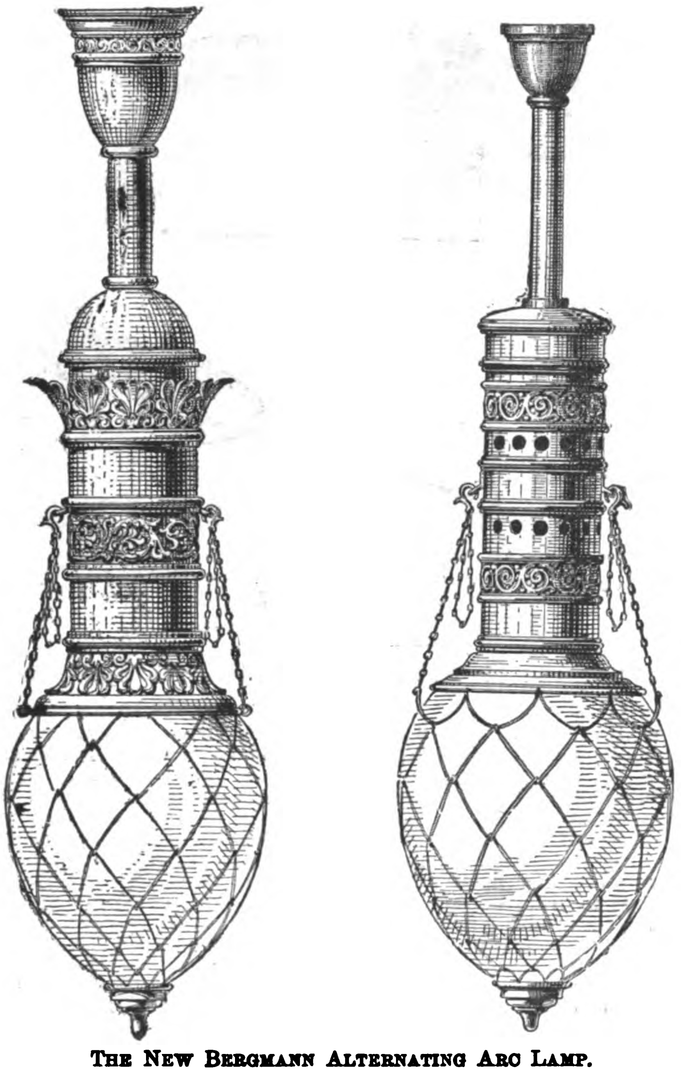
FIGS. 1 AND 2.—THE CENTRAL ELECTRIC NEW MAIN LINE SWITCH.

One of the most important points in a circuit breaking device is ample carrying capacity. This has been provided for by making the contact clips and blades relatively large, giving great contact surface. The blades are hung loosely in their supporting bars, thus insuring perfect alignment of the tongues with the clips. The most salient feature of the switch, however, is the arrangement for securing a quick break, independent of the movement of the switch-arm or handle. As clearly shown in the engravings, the upper side of each switch arm carries a stiff, flat steel spring, connected by a small rod to the lower edge of each blade. The friction between the contact clips and blades is sufficient to put the spring under tension whenever the blades are withdrawn from the clips. As soon, however, as the blades are about to leave the clips, the force of the springs asserts itself, causing the blades to be suddenly withdrawn a sufficient distance to prevent arcing.

Incidentally, the peculiar arrangement of the springs secures another important advantage, consisting of a longitudinal movement of the blades, in addition to the usual up and down motion. This insures a good rubbing contact so essential in devices of this kind. The springs, being of the best tempered spring steel, retain their elasticity at all times. The switch is well made and of neat design, all the parts being properly proportioned, without giving a clumsy appearance to the switch itself.

THE NEW BERGMANN ALTERNATING ARC LAMP.

One of the distinctive features of the electric lighting industry during the past year has been the marked increase of interest in the subject of arc lighting on alternating current circuits by means of the so-called incandescent arc lamp. The new Bergmann alternating current lamp now being put on the market by the General Incandescent Arc Light Co., of New York, and marks an important step in the march of progress in this direction; important both to the public and electric illuminating companies. As in the case of their direct current lamp, this company manufacture their alternating current incandescent arc lamps in various styles and degrees of ornamentation, from the plainest so-called "Standard" lamp, which is itself sightly in appearance and neat in design, to the most elaborate creations of the metal-worker's art. The accompanying illustrations show two representative forms of these.



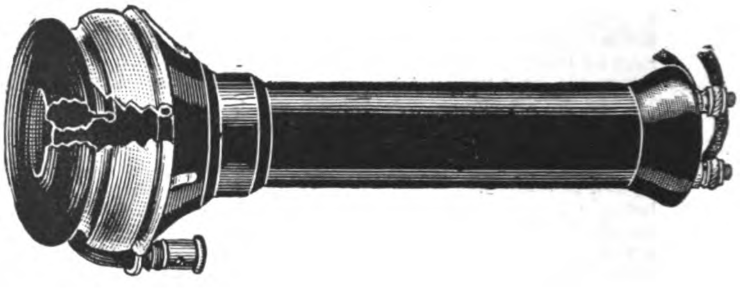
THE NEW BERGMANN ALTERNATING ARC LAMP.

The lamps burn steadily and give as pleasing a light as the successful direct current lamps, and we are informed that all the lamps of this type that the company have thus far shipped are without any known exception giving perfect satisfaction. The company's handsome illustrated circular No. 7, which can be obtained by mail, gives a full account of the claims made for these lamps, some of which may be briefly stated as follows: Simplicity of mechanism, first-class workmanship, absolute steadiness without adjustment, ease of trimming, protection from dust and weather, starting at less than the normal current, requiring no waste of current in resistance, large range of candle power and improved carbon-holders.

The company will have their lamps on exhibition during the Convention, where they will be represented by their general sales agent, Mr. S. A. Douglas, who will go into the details and show all the points of excellence and beauty of the incandescent arc lamp to his numerous friends who may be expected to be present at that reunion of the various electric light interests.

THE COOK PNEUMATIC ATTACHMENT FOR TELEPHONE RECEIVERS.

Mr. V. A. Cook, of Averill Park, N. Y., has invented a pneumatic attachment for telephone receivers shown in the accompanying illustration. It consists of a metal band with spring clamps by which it is fastened to the receiver. To this is fixed a soft rubber cushion with a tube and valve, for inflating it with air. The device is said to be easier upon the ear than the hard rubber receiver. It fits closely and shuts off outside rounds, and also tends to lessen the annoyance from induction effects.



THE COOK PNEUMATIC ATTACHMENT FOR TELEPHONE RECEIVERS.

THE "ACME" STANDARD VOLTMETERS FOR DIRECT AND ALTERNATING CIRCUITS.

FOR some years the Cardew Voltmeter was recognized as the only standard available for alternating circutits. However, as commercial electricity advanced and study was devoted to instrument construction as well as to heavier problems of engineering, it became evident that the Cardew instrument possessed certain defects hitherto unnoticed, as also that an instrument in which these defects were eliminated was urgently required. Recognizing these facts and being convinced of the intrinsic superiority of the "hot-wire" principle, Messrs. Queen & Co., of Philadelphia, through their electrician, Mr. Willyoung, undertook a thorough

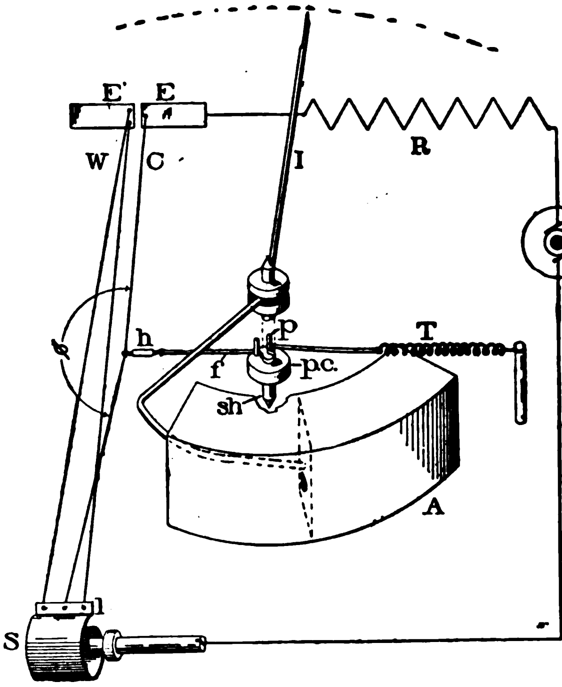


FIG. 1.—THE "ACME" STANDARD VOLTMETER.

study of hot wire instruments with the object of developing a complete series both portable and for station purposes, which should be thoroughly adapted to the requirements of the most exacting practice.

Fig. 1 illustrates, diagrammatically, the essential working parts of the portable instrument. The "hot" or working wire, C, extends from a fixed support, E, to a spirally wound phosphor bronze spring, S. Midway of its length it is connected to the extremity of a phosphor bronze filament or strip, *f*, which passes around the index shaft, *s h*, engaging as it goes with two small pins *p*; the other extremity of the filament *f*, is attached to a spiral "take-up" spring, T, whose outer end is fixed. It is obvious that for a very small linear expansion of the working wire, C, there will be caused a many times magnified movement of the middle point in the line of the filament, *f*, which movement being taken up by T, results in the carrying of the index I over the scale. The wires W, are two or more in number, each of the same or nearly the same cross-section as C, and attached at one end to the fixed plate E^1 similar to E but insulated from it, and at the other end to the spring, S, to which it is attached. These wires, not carrying any current, serve to restrain S from taking up the expansion of C when current is passing, but, being affected by general changes of temperature to the same degree as C, let out S just enough for such changes to take up the linear expansion of C, thus preventing any change of zero of the pointer for varying temperatures. It should also be observed that this compensation is effected instantly no matter how varied the changes of temperature, since the wires W, are of the same or nearly the same cross-section as C. In the Cardew voltmeter the wires W, are equivalented by composite rods of iron and copper having the same coefficient of expansion as the "hot-wire" which gives perfect compensation but only for slow changes of temperature. In all hot wire instruments, however, the temperature of the working wire rises continuously for some time after the current is thrown on since the radiated heat will raise the temperature of the chamber containing the working wire until the rate of radiation from such chamber exactly equals the rate of generation of heat within it. Hence the working wires will continue to expand and the reading to increase unless compensation takes place instantly and one end of the working wire be let out exactly in correspondence with the fictitious expansion, as it may be called. In the same way an instrument compensated with rods will read low if a low reading is made to immediately follow a high reading. In the "Acme" instruments, it is claimed, absolutely no variation in reading can be detected whether the current be on for a second, a moment, or an hour and the readings going to any point from zero are exactly the same as when dropping to the same current value from a higher one. The spiral spring, S, is used in preference to an elongated spring on account of the fact that in an instrument in which the forces involved are so small as in the "Acme" the effect of gravity upon a long spring would be considerable and would cause the readings to be less or greater according as the spring were lower or higher than the other end of the wires and small changes of level would, therefore, have to be guarded against. Upon the form of spring used gravity has no effect and the readings are therefore not appreciably affected by very considerable differences of level; this freedom from level error is greatly assisted by the fact that the index is very accurately made and balanced so as to have its centre of gravity in its axis.

The filament, *f*, is attached to the wire, C, by means of a minute glass connector, *h*, provided at each end with equally minute hooks of platinum wire to interpose between the wire and the filament an effective insulation, thus avoiding any risk of accidental short circuits in other portions of the instrument. A very important function in this instrument is performed by the filament, *f*, and the collar, *p c*, with its pins, *p*. All hot wire instruments, as was premised, give indications practically proportional to the square of the current since the total heat developed in any circuit is C^2 R, and R, in the alloys, varies so little as be negligible in comparison with C. The scales of such instruments, therefore, are exceedingly crowded at first and open up more and more toward the upper end varying in size proportional to C^2.

The particular arrangement of filament and collar just referred to, was devised to secure a fairly uniform scale and it performs its duty admirably. The manner of its operation may best be seen by inspection of Fig. 2, which represents enlarged diagrammatic views of the arrangement at zero and full scale deflection for two different positions of the collar, *p c*, with reference to the pinion, *s h*. The collar, *p c*, carrying the two pins, *p*, can be set upon the pinion, *s h*, so that the angle between the pins *p*, and the pointer may be made anything desired. Referring now to Fig. 2*a* we see that the collar has been so set as to make $\theta = 90$ degrees. This causes the bend in the left hand side of the filament to be very little at the zero point and hence the effective radius of action of this part of the filament upon the shaft, *s h*, to be very short; a very small movement of the working wire is, therefore, considerably magnified by the index. At position *b* of the same figure, however, the bend in the filament has become great and the effective lever arm long. Consequently, the scale divisions which would be proportional to C^2 did the filament simply wrap about a cylindrical shaft are greatly shortened and the general tendency of the whole is to even up the scale throughout its entire range.

Fig. 3 shows one of the perfected forms of this voltmeter, intended for inspectors, engineers, and others having accurate testing to do in various places. The extra resistance R of Fig. 1, is wound (for all ranges above 75 volts) in sections, in coil form and non-inductively, of double covered silk wire thoroughly soaked and baked in shellac. No two neighboring wires can have, therefore, more than 75 volts difference of E. M. F. In order to use as fine a wire for this extra resistance as possible and thus diminish bulk and weight, the extra resistance coil is clamped between two aluminum plates made part of the lid of the instrument, a pair of small flexible leads connecting it with the working wire.

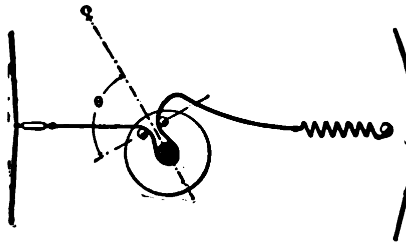

FIG. 2*a*.

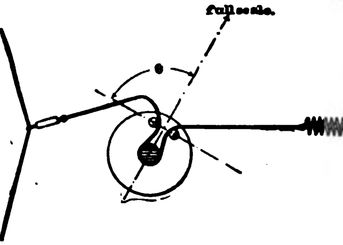

FIG. 2*b*.

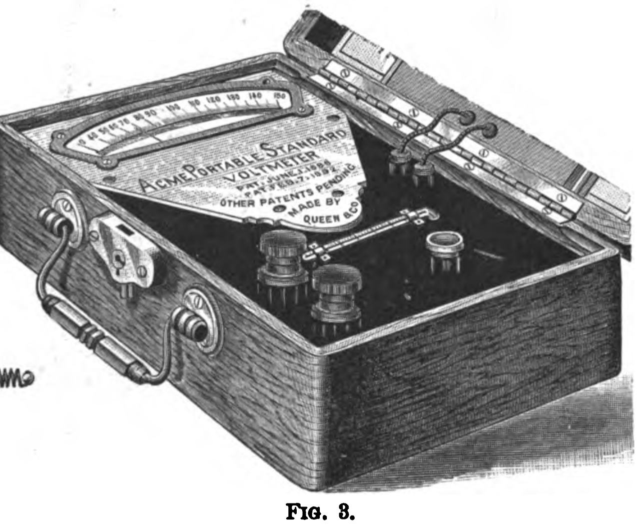

FIG. 3.

THE WILLIAM LANG CO.

An event of general interest in the electrical field, is the change recently made in the management of the above company, which will now have as its officers: T. E. Conklin, president; E. F. Gennert, vice-president; F. W. Belmont, treasurer, and J. F. Cunningham, secretary. The three last named were connected with the firm of E. P. Gleason Mfg. Co. for 22, 12 and 16 years respectively. Mr. Gennert is widely known not only from that association of such long standing, but through his many inventions and improvements in electric lighting, electric gas lighting and other fixtures and details. The factory of the William Lang Co., at 123 to 139 Middleton street, Brooklyn, N. Y., is one of the largest of its kind, and does all manner of stamping and metal drawing. They build in large quantities, and very successfully, automatic vending machines, watch cases, magic pocket lamps, and many other of the little metal novelties that one sees at every turn. The company will now manufacture electrical appliances and fittings, and is constructing and changing machinery for that special purpose. Mr. Gennert and his colleagues have a number of important devices which they will spring upon the market and the public at an early date.

RIES ELECTRIC SPECIALTY CO.

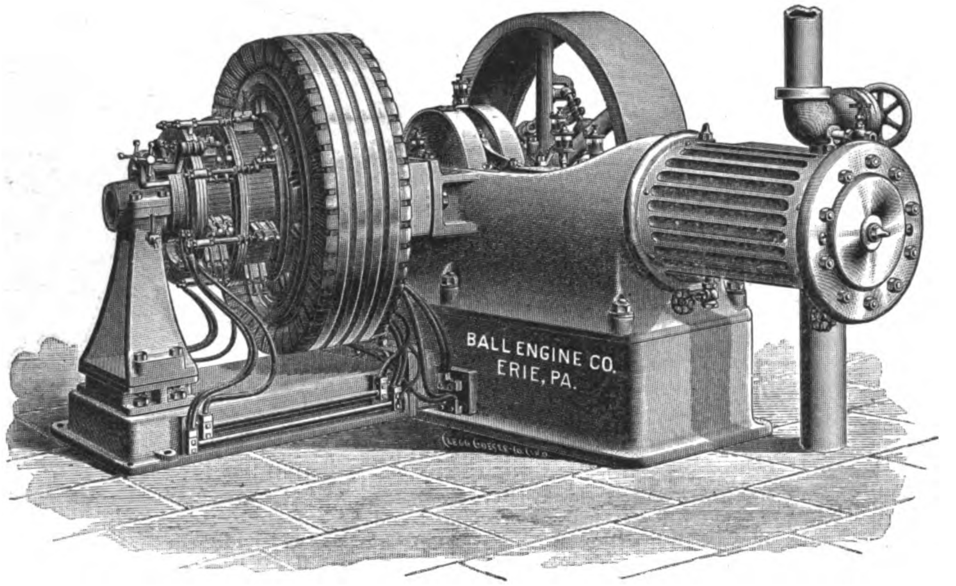
AN invitation to the members of the National Electric Light Association is extended by the Ries Electric Specialty Co., of 7 South Gay street, Baltimore, Md., to visit them at that city for the purpose of seeing the advances made in the development of the Ries & Scott single phase alternating current motors, which are to be put upon the market during the present year.

THE BALL DIRECT CONNECTED ENGINE AND WADDELL-ENTZ GENERATOR.

The progress towards the ultimate perfection of electrical machinery is perhaps manifested in no way more clearly than in the present use of engines directly connected to dynamos. The small floor space occupied is an important consideration in large cities where there is a steadily increasing demand for economy in this direction and a no less important advantage in the elimination of waste of energy by transmission through belts and counter-shafting, leaving nothing but the internal friction of the engine to be accounted for.

The Ball Engine Co., of Erie, Pa., have made a number of installations in connection with various types of dynamos. Among the latest ones are two 200 h. p. cross compound engines, directly connected to Siemens & Halske dynamos in the Lumber Exchange Building, Minneapolis, Minn.; one 125 h. p. simple engine, in connection with a Waddell-Entz dynamo, in the store building of Willoughby, Hill & Co., Chicago; and one 80 h. p. engine, in connection with a Waddell-Entz dynamo, in the building of Cumner, Craig & Co., of Boston. The last of these three is shown in the accompanying illustration. The armature is mounted on the engine crank shaft, which is supported on the end by an outboard bearing resting on an extended sub-base. This is a remarkably compact, durable, and efficient arrangement, and has given the greatest satisfaction in practice.

The distinctive features claimed for this well known engine are: Beauty of design, simplicity and compactness, solidity and strength of frame, large bearings and wearing surfaces, excellence of materials and workmanship. The engine, therefore, is economical and durable, and, being perfectly balanced, will, it is said, run quietly and smoothly under the heaviest and most widely varying loads, with a regulation so perfect that the engine will not vary to exceed one per cent. in speed. Every detail of construction receives the most careful inspection and every engine is thoroughly tested before shipment is made.



BALL ENGINE CO.
ERIE, PA.

THE BALL DIRECT CONNECTED ENGINE AND WADDELL-ENTZ GENERATOR.

PHILADELPHIA NOTES.

THE GENERAL ELECTRIC Co. are installing an electric light plant for Boyd, White & Co., 1330 Chestnut st.

WALKER & KEPLER have received a contract for two Siemens and Halske generators to be installed for Wm. Maine & Co., of 5th and Commerce sts.

HARRY S. SMITH AND CO., LTD., are installing all the electrical work in the new Chemical Laboratory of the University of Pennsylvania. Current will be supplied from the plant in the Engineering Building; a lead-covered cable will run under 34th street from the Engineering Building to the Laboratory. This company report business very fair. They have just completed the installation of two 80 k. w. Waddell-Entz generators direct coupled to Ideal Engines at the Norristown Insane Asylum and will soon have completed the entire electric light installation for the new Hotel Hanover. In this plant Eddy generators and New York Safety engines directly coupled will furnish light for the building. The company have also done the electrical work for the temporary lighting for the Philadelphia Cycle show and a reproduction of "The Midway Plaisance" given at the First Regiment Armory.

THE electric light plant for the Bank of North America will be installed by the Electro-Dynamic Co. The plant will consist of two 30 k. w. Electro-Dynamic dynamos directly coupled to Straight Line engines.

NEW YORK NOTES.

MR. CHAS. E. CHAPIN is now handling the well known Miamisburg dry batteries in addition to his other lines of electrical supplies.

MR. NELSON W. PERRY, E. E., has been awarded the John Scott Legacy Premium and Medal by the Franklin Institute of Philadelphia, for his interesting series electric traction system, which he brought to the attention of the public recently, and to which he made reference in a valuable paper read before the American Institute of Electrical Engineers in 1892.

MR. M. D. VAN BUREN has been appointed chief engineer of the fine new building of the Hanover Fire Insurance Co., 34 Pine street, which will be lighted by 1,100 incandescents. The wiring is in Interior Conduit. The generating plant consists of two Ideal engines driving directly connected General Electric multipolar dynamos with outboard bearings. The boilers are of the Worthington type, made by the New York Safety Steam Power Co. The elevators are Otis.

THE GENERAL ELECTRIC COMPANY will be represented at the Convention by the following gentlemen: Messrs. S. Dana Greene, A. D. Page, J. R. Lovejoy, Wilson S. Howell, F. Todd, A. B. Herrick, R. H. Beach, T. Beran and others. Delegates to the Convention will have the opportunity of examining the new Thomson arc lamp for incandescent circuits, the new recording wattmeters for arc and railway circuits, and several other devices both of economy and novelty.

THE attention of electrical engineers is directed to the "Samson" turbine water wheel built by the James Leffel & Company, Springfield, O. This wheel is furnished in a number of different styles on upright and horizontal shafts and is specially designed and adapted for driving electric lighting and power plants.

MR. W. B. VAN SIZE, who has long been before the electrical public as a patent attorney and expert in electric light, railway, telephone, accumulator and other branches of the art has now established himself independently and has opened professional offices at 44 Broad street. Mr. Van Size has had an experience dating back to and including the practical development of many electrical inventions of importance, and his services have been found highly valuable by more than one of the leading inventors and corporations. Now that his time and ability are at more general disposal, his clientage will rapidly increase.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XVII. MARCH 7, 1894. No. 305.

ELECTRIC HEATING AND ITS RELATION TO CENTRAL STATION WORK.

BY

W. S. Hadaway Jr.

CENTRAL station men are familiar with heating by electricity when applied to the filament of an incandescent lamp to produce light. The only disadvantage of this method of application of electricity is the short period of time the investment is productive capital, necessitating excessively high rates to cover operating expenses and fixed charges. The lamp rate as ordinarily charged on the basis of ten cents per horse power hour, figure $300 per electrical horse-power per year (assuming 300 working days, 10 hours per day.) Mechanical horse power can be freely purchased in populous centres for $75 per H. P. per year, or one-fourth the amount charged for electrical horse power at the lamp rate.

This excess charge is not wholly due to the difference in time during which the plant is productive capital; but we may safely state that if the horse power capacity of the station could be utilized for as much of the time as the average mechanical power plant is utilized, the rate of 5 cents per H. P. hour (one half present average lamp rate) or $150 per H. P. per year would yield larger net profits than are now obtained from lamp rates at the price charged. This claim is substantiated by the power rates of the Edison central station companies. The lamp rate of these companies is nearly on the basis of ten cents per H. P. hour. The power rates are on a sliding scale, with discounts up to 50 per cent. on monthly bills of 1,500 H. P. hours. That is, the user of 6 horse power, 25 days per month, 10 hours per day can purchase an electrical horse power hour for 5 cents.

The logical conclusion is that if the load now furnished by lamps and motors could be increased, especially at the time of light lamp service, the investment would become still more profitable, even at lower rates for the additional power than are at present charged for motor service. That is, if the area between the ordinate and the load line can be greater, and averaged, so that each hour of the day the plant is supplying large units of power, lower average rates will prevail, which will extend the general business, and yield larger net returns.

A well designed central station of moderate size produces a horse power hour by the combustion of about 3 lbs. of good coal. The electrical horse power hour developed by this coal has 2,565 heat units; we have to balance these 2,565 heat units in the concentrated form against 42,000 heat units existant in the three pounds of coal in a more diffused state and determine whether, *for heat purposes*, the difference in the form of the energy, with its enormous attendant losses, compensates for the energy lost in bringing the heat units of coal into the higher form of energy capable of economical transmission to a distance.

It is found in practice that the commercial efficiency of the coal cooking range is somewhere between 3 and 6 per cent.; these limits are stated by Tyndall. In a recent discussion before the London Society of Engineers, Nov. 6, 1893, Mr. Beaumont gives the efficiency of the cooking range from experiments of his own as 3.7 per cent., or roughly 4 per cent., indicating, that of every 27 pounds of coal burned, 26 pounds are thrown away. We have seen that the heat efficiency of the average moderate size central station is about 6 per cent. There is sufficient margin between a heat efficiency of 3.7 per cent. and one of 6 per cent. to warrant the use of electricity as a source of heat in domestic life, and a further extension with apparatus of larger size and higher working economy would give a still greater margin between coal burned under the boiler and that used in the fire-pot of the range. Thus with the use of only 1½ lbs. of coal per h. p. hour he would secure a commercial efficiency of 12.2 per cent. or 3.3 times the efficiency of the range.

At the outset, of course, the cost of electrical energy as fuel under average conditions at the power rate will be greater than fuel directly burned. But there are compensating advantages gained which more than offset the additional cost. This has been abundantly proved in actual practice. The saving of attendance, and of time, freedom from dirt, coolness of the kitchen, absolute uniformity of heat and ability to regulate it, appeal at once to the householder. There is merit aside from novelty in such practice.

The use of electricity for lighting is, of course, greatest in the winter time and least in the summer time; the most desirable uses of electricity as a source of heat are found in summer work, for from the nature of electrical energy, it admits of localization and it is this method of heating that is sought in the summer to reduce discomfort from radiation, etc. Thus by what we may term a "condition of compensation," the central station man has at his command apparatus useful in equal degree in summer and in winter, and the means of securing a larger net revenue at lower rates by using the plant for a larger percentage of the day. The time of maximum cooking being generally the time of least lighting, and vice versa.

In industrial work wherever flames are used to secure localized heat, electricity can be advantageously employed. It is more easily regulated than flame, there are no unhealthy products of combustion, the mean temperature of the shop is lowered, the temperatures are constant, the work is more uniform and the entire system cleaner and more complete. For factory use it is the most desirable form of fuel. In laundries, clothing manufactories, hat factories, silk and all textile fabric mills, shirt factories, rubber goods manufactories, furniture factories, etc., are good fields for the use of electricity for heating. In domestic life no source of heat offers so many elements of value as the use of electricity for cooking and laundry work. There is no discomfort, no noxious gases from combustion, and the temperatures attained are constant, so that the question of the discretion of the cook is eliminated and better results obtained than can possibly be reached from the approximate temperatures of surfaces heated by combustion. It may be fairly stated that people who could afford to do their lighting by electricity could afford to do their cooking and ironing by the same means.

Electricity for heating will be found of the same value to central station electric lighting companies as the use of gas for fuel purposes has proved to the gas lighting companies. Its value lies largely in ability to localize the heat, and it will not be found desirable to use it on a large scale where diffused heat is wanted. High temperatures and small quantities are the proper uses for electricity for fuel. It will, however, meet a want as an auxiliary to the regular heating system, for warming bath and dressing rooms and other small rooms, at times when it is not desirable to use the regular system, say in the spring and autumn months and in chilly days.

Those stations operating from water powers may judge of the applicability of electricity for heating by the foregoing remarks. The cheaper the energy can be sold, the wider the field of application, and with water power the more electricity that can be sold the greater the revenue. With large water powers electricity in competition with stoves may be considered in house heating; but not in large buildings in competition with a good steam or hot water heating equipment.

THE LIMITATIONS OF THE DIRECT CONNECTED DIRECT CURRENT GENERATOR.

BY

J. B. Cahoon

I NOTICE in your last issue, an article on the advantages of direct connected direct current generators, by Mr. W. N. Stewart, in which he makes some very sweeping assertions as to the economical operation of this class of machines, and more particularly of stations supplied with such. It is possible, that Mr. Stewart may be riding a hobby, and is therefore blinded to ordinary commercial facts. For instance, in obtaining his economical results, he states that, "If one belt direct from the engine is used, 10 per cent. is lost; if a counter shaft is used, 18 per cent. is lost;" whereas in actual practice with good belts and a proper system of counter shafting, we may safely take as a conservative estimate of the loss due to the use of belts the following: For horizontal belts direct from engine to machine, 5 per cent.; vertical belts, 8 per cent.; for counter shafting using horizontal belts, 10 per cent.; and using vertical belts, 15 per cent. And again, Mr. Stewart makes the assertion, that with the class of machines he would employ, there would be no burnouts in either field or armature, and there would be less oiling and fewer employees necessary to run the plant, while there would be no loss in the transformers, etc. Evidently, according to Mr. Stewart, it does not cost anything for men to take care of storage batteries and therefore this is not an item of expense in his plant, whereas, we find in everyday practice from stations using storage batteries, that not only the care of them, but also the cost of renewals of the plates and cells, is quite an item of expense.

Again, in attempting to distribute over any wide area by means of direct current, either by three or five wire system from a storage battery, or any other source of continuous direct current, it is obvious that much more copper will have to be laid down than would be the case were resort had to the use of the alternating current at a pressure of one or two thousand volts, and this is particularly the case in the distribution for lighting in small places, where the area to be covered chances to be some little distance from the source of power, as is illustrated by the plant at Peterboro, N. H., a description of which was given in the ELECTRICAL ENGINEER, some little time ago. In a case like this, the direct current generator could not be employed and pay a dividend, whereas the opposite is the case with the alternating plant. Again, Mr. Stewart assumes that such a thing as a direct connected alternator does not exist in actual use, and that those who are using the alternating current are only a lot of ignorant people who are some years behind the times. This is a very decided mistake on the part of Mr. Stewart, as several of the large companies are installing the direct connected alternator at the present time, and have been, for some little time past.

There is another point that should not be passed over, and that is that, from all the data I have been able to obtain in the course of the last two years while particularly seeking for data of this nature, I do not think Mr. Stewart is right, or can be sustained, in making the assertion that the direct connected generator of any or all sizes is the thing to use under all conditions where direct current is to be used; for as a matter of fact, I know of quite a number of instances, where the question as to which would be more economical,—direct connected, or belt driven generators of under one hundred kilowatts capacity,—was settled in favor of the belt driven generator for these small units as being likely to give less trouble and being more economical in the long run. Therefore, it seems to me, the broader ground should be taken, that a machine should be installed of such a kind, either alternating or direct current, and to be belt or direct driven, as may be best suited for the location and work to be done.

As regards the use of storage battery, much has been written on this, and there have been many advocates in its favor, while others have argued against its use; but there can be no question that storage batteries are gradually creeping into use in the American station as an auxiliary to the ordinary apparatus in the same way that they have in Europe, although, it is to be very much doubted if they will ever be as extensively used in the stations here, as they now are abroad.

A STORAGE BATTERY CHALLENGE.

In order to put at rest the conflicting statements circulated as to the merits of their Chloride Accumulator the Electric Storage Battery Co., of Philadelphia, have issued a challenge, inviting all American storage battery manufacturers to enter their batteries for a competitive test. Each competitor is to deposit the sum of $500 and the Electric Storage Battery Co., is willing to forfeit its deposit if its Chloride Accumulator does not prove to be at least 50 per cent. better in efficiency, capacity and durability than that of any of its competitors. Messrs. Houston and Kennelly, electrical experts, Betz Building, Philadelphia, have signified their willingness to undertake the tests and have drawn up a complete schedule of condititions under which the tests are to be carried out. The challenge is open for 90 days from March 1, and parties desiring to enter the tests are requested to communicate with Messrs. Houston and Kennelly. The full conditions of the tests appear in our advertising columns.

ELECTRICAL FIRES.

Mr. Wm. H. Merrill, Electrician of the Chicago Fire Underwriter's Ass'n has recently issued his second report of Committee on Fires, giving 77 instances where fires were caused, or said to be caused, by electricity. The list is very interesting and instructive, showing that in nearly every instance the damage could have been prevented by using better wiring material or by exercising a little common sense in the use of the appliances. Such cases, for instance, as the following are inexcusable and show the necessity of rigid enforcement of some of the underwriters' rules.

"Bell wire tapped to incandescent 50 volt alternating circuit by employees in building, cotton and paraffine insulating covering ignited. Loss considerable."

Other cases show that the rule first suggested by Mr. C. C. Haskins, "Fix it so it can't and it wont," does not get the attention it deserves. On the other hand, an item like the following might as well be omitted from a list purporting to give the fire losses caused by electricity:

"Electric street railway power station. Fire caused by dropping an oil lantern, Total loss."

FAULTS INCIDENT TO THE PROTECTION OF LIGHTING AND POWER CIRCUITS.[1]

BY LUCIUS T. STANLEY AND WALTER E. HARRINGTON.

In the present state of the art there are two common methods of protecting electric circuits, viz.: By means of metallic fuses and by means of magnetic cut-outs.

Metallic Fuses.—To adopt the language of a noted company, which is a large manufacturer of metallic fuses in various forms, "fuse wire is a safety device designed to break the electric circuit when an excessive current passes, and it breaks the circuit because it is heated to a temperature at which it melts." Such a device as is thus defined would be a perfect protector to electric circuits if it were possible to predetermine absolutely—first, the current it will safely carry indefinitely, and, second, the actual current in excess of this safe normal load that will "blow" the fuse *instantly*, under any and all conditions of lapsed time, character of service, etc.

The authors then give a list of the principal causes which render it impossible to devise a metallic fuse that is absolutely and under any and all circumstances a protector to an electrical system, and express their belief that in the present advanced state of the art fuses are not only totally inadequate and inefficent but actually dangerous.

The Magnetic Cut-Out is commonly defined as *a device which opens the circuit at a set strength of current.* In the light of certain phenomena brought forth by experiments made by the writers, they believe that this is not a full and complete definition. In fact they think it is misleading. They then give the general principles governing all the various forms produced by the several manufacturers, including the long-throw knife blade switch, operated by a trip actuated by the armature of an electro-magnet, and a device for blowing out the arc. The arc can be broken by an auxiliary break or by the electro magnetic blowout. The authors then discuss the difficulties encountered with this type of apparatus, and conclude as follows:

A magnetic cut-out which would exhibit a long stride toward ultimate perfection would be a switch operated to open by the *direct action* of a magnet upon the switch bar in such a manner as to cause the current itself to drive the bridge away from the switch plates, thus insuring the quickest possible response to an abnormal current. The break at the switch terminals should be protected by a by-path or shunt across the switch terminals, composed of a fuse wire of a carrying capacity sufficient to carry the current for a period of time ample to allow the switch bridge to reach a point of safety, and of a fusing capacity that will cause it to "blow" *instantly* when the switch bridge has thus reached a point of safety. The magnetic circuit should be so arranged that the point of saturation would be beyond the capabilities of the flux incident to the opening of the switch upon the passage of a current at which it might be set and expected to open. Consequently, when abnormal currents, in excess of that at which the switch was set to open, occurred, the result would be an acceleration of movement of the plunger up to the point of saturation, and the *time element* would thus be reduced to a minimum.

THE IMPORTANCE OF COMPLETE METALLIC CIRCUIT FOR ELECTRIC RAILWAYS.[1]

BY J. H. VAIL.

The author stated that many devices for making the track and earth combined a more complete and low resistance circuit had been resorted to, such as burying copper or iron plates, old rails or old car wheels, and connecting them to the track; or, at frequent intervals, driving iron rods down in the earth and connecting by wires to track; or by making actual connection with wire from tracks to gas and water pipe systems. For *supposed* reinforcement of the track, a bare wire of iron or copper has been used buried in the earth, laid parallel to the track, and connected at frequent intervals; also the *supposed* electrical connection of rails at joints, by bond wires of iron or copper, having only a small fractional part of the capacity of the rail as a conductor.

Frequent tests prove that the earth itself cannot afford the free path for the current that was anticipated. Earth conductivity has been overestimated. Iron and lead pipes, being better conductors than earth, must of necessity carry the current, if no superior path is offered by the method of construction. The natural moisture of the earth hastens the destructive electrolytic action of the current on these pipes. In some soils electrolysis is more rapid than in others. The rapidity of action depends upon the chemical constituents of the soil.

It has been stated that in an electric railway system where a connection has been made to water pipes, the pipes have carried as much as twenty-eight per cent. of the total current. Instances are known where as much as forty per cent. is carried on the pipe systems. It has been proved by test that the electrolytic action of even five amperes of current on an iron pipe is considerable, and that much damage will result in one year. The rapidity of action depends upon the character of soil, amount of moisture and quantity of current; the destructive action is constant and sure. Any system using ground plates, ground rods or substitutes therefor, or bare return track wire buried in the earth, is constructed primarily to utilize the earth as return circuit; when the earth does not afford good return the current is sure to follow the water pipes, gas pipes or other buried conductors offering the path of least resistance. We now see that these prove to have been only make-shift methods to reduce the cost of construction.

With the electric railway, the track forms one side of the consumption circuit, and must be so treated in regard to distribution of current as to utilize its carrying capacity equally with the other side, and thus equalize the delivery of current. The electric conductors composing a system of distribution for electric railways should be so thoroughly well proportioned as to show the minimum variation of pressure throughout the system, even when all the cars are in operation. This equality of pressure is an important requisite for the economical working of the motors. The author has tested electric railway systems operating with a station pressure of from 500 to 550 volts, and showing only 300 to 325 volts on various divisions of the system. Here is a direct loss between dynamos and motor car of over forty per cent. Is it, therefore, any wonder that some roads report extraordinary coal consumption? Such loss in pressure indicates radical faults in the original planning of the system and the distribution of copper. The rail sections are in many systems of ample conductivity to carry more than the requisite current, provided they are perfectly bonded and properly connected by feeders with the dynamos. We must, therefore, bond the rail joint in such a mechanical manner as to maintain perfect electrical contact, and with sufficient metal to restore at the joint nearly the full conductivity as that of the rail itself; and at the same time to give the existing joint plates their present freedom of motion.

For the purpose of comparison, we will assume that iron has six times the resistance of copper.[2] (The actual proportion being 1 to 5.63).

	56 POUND RAIL.		70 POUND RAIL.	
	ONE RAIL.	SINGLE TRACK OF TWO RAILS.	ONE RAIL.	SINGLE TRACK OF TWO RAILS.
Area in sq. inches..........	5.4874	10.9748	6.8593	13.7186
Equal in area to circle whose diameter is in inches..........	2.642	3.735	2.95	5.90
Equivalent in cir. mils. to........	6,980,000	13,960,000	8,702,500	17,405,000
Resistance per foot B. A. units	.00000845	.00000422	.00000679	.00000339
Equivalent to copper resistance in cir mils	1,175,000	2,350,000	1,463,000	2,926,000
Equivalent to copper rod whose diameter is...............	1.13	1.533	1.21	1.71
Safe carrying capacity of iron reckoned at ⅛ that of copper in amperes....	390	780	488	976

NOTE.—In the above statement the areas of rails have been determined by use of the planimeter. The ampere capacity of iron has been based upon the most reliable data obtainable. The author believes that the figures submitted are sufficient for comparison, but cannot guarantee their absolute accuracy.

The following table[3] gives the current strength that can be carried by iron wire, within doors, in still air, and without becoming unbearably warm to the hand; that is, not to exceed a temperature of 50° Centigrade:

B. & S. gauge...........	10	9	8	7	6	5	4	3	2	1	0	00	000	0000	½"	¾"	1"
Amperes................	16	19	21	25	28	32	37	43	50	58	67	77	90	105	117	208	302

These figures serve to show how utterly absurd it is to bond a track of seventy-pound T rails with iron rail bonds No. 4 or No. 0 in size, and to pretend to reinforce their conductivity with a No. 0 iron or even a No. 0 copper wire. It is like laying a twelve inch water main and then putting a one-half-inch pipe alongside to help it out. The author believes that ninety-nine per cent. of the money expended for so-called supplementary wire is absolutely thrown away. The same money expended in other directions will give more adequate return. The track system of all electric railways should really be the positive side or outgoing circuit. It will be readily understood that as the current travels from positive to negative, therefore any arc which occurs between the trolley wheel and the trolley wire will carry metal from the trolley wheel and deposit it on the trolley wire. If the reverse method of connection is made, the trolley wire will lose the metal which will be deposited on the trolley wheel, and in time the strength and conductivity of the wire must be seriously impaired, eventually resulting in breakages.

---

[1] Abstract of a paper read before the National Electric Light Association, Washington, D. C., Feb. 27, 28 and March 1, 1894.

[2] Table prepared by G. F. Sandt, E. E.

[3] Data furnished by A. E. Kennelly.

The author here stated that a trial was made four years ago under favorable conditions—not to avoid electrolysis, but to save copper. Physical difficulties of operation were developed which warned the experimenters to avoid the three-wire system in future electric railway work. Having carefully analyzed the whole matter, he now felt justified in recommending the complete metallic circuit as the standard for the best electric railway practice. This can best be obtained by the following method: First. By so bonding the track as to render the rail joints of as low resistance and nearly equal conductivity to the rails, and to execute this work so as to maintain this improved condition; and, Second. The track system must be supplied with insulated feeders leading directly from the bus bars in the station to predetermined points of the track system, and thus offer a perfect low resistance path for this side of the electric circuit, the same as is obtained with the trolley line and the overhead system. All of these features and improved methods have been put in practice by the author.

The item of cost cannot properly be urged as an objection, because where the whole construction requires a large investment, every detail of the work should be so executed as to be permanent and enduring. The track feeder system will be far less costly than the double trolley system. Whether track feeders should be laid underground or erected overhead is a question largely controlled by local conditions and capital available. The author expressed a preference for underground work as being more permanent and subject to the least cost for repairs, and has provided for all contingencies in the following manner: First. By a careful study of the conditions under which a system will be operated; these important points being ascertained with reasonable accuracy, the requisite supply and distribution of current for the service is determined, and the system of conductors arranged to meet the requirements. For the proper supply of electric current, the important underlying principles of the feeder system must be thoroughly understood. Second. The conductivity and current-carrying capacity of the track system is calculated, and a system of insulated track feeders is provided, leading from the switchboard in station and connecting at predetermined points, and with a calculated fall of potential.

A Pipe Attacked by Electrolyzing Currents in the Street.

This will be found to result in reduced fuel consumption, better working of the motors, a most satisfactory reduction in repair accounts, and an improved general economy of the entire system.

In the system of distribution secured by the above method, the use of ground plates, rods or other insufficient methods it needless; the current travels only over the paths provided for it, and electrolysis of gas and water mains is entirely obviated.

REPORT OF THE COMMITTEE ON DATA.[1]

BY H. M. SWETLAND, T. CARPENTER SMITH, E. F. PECK, G. G. H. BLAXTER, C. E. SCOTT, *Committee.*

We are requested to furnish this convention with the facts regarding the amount of coal used in actual practice to produce a given quantity of electricity. The information was obtained by correspondence, and furnished the committee in amperes, volts, and hours on each circuit, and the amount of coal used covering this period, including that used for banking fires, etc. The aggregate electrical output for twenty-four hours was then calculated and compared with the total amount of fuel used, giving the watt-hours per pound of coal. All improbable and apparently erroneous reports were discarded, and the tabulated statement herewith comprises intelligent replies from a large number of the electric stations, including many of the leading corporations. The great saving in operating in large units and running continuously is plainly shown by the report which shows 208 watt-hours

Hours.	Amperes.	Volts.	Watt-hours.	Pounds Coal.	Kind.	Watt hours per lb. Coal.

Average Watt-hours per pound coal, 91.7.
Where there are blanks in the table, details were not given.

---

[1] Abstract of a Report made at the National Electric Light Association meeting, Washington, D. C., February 29, 1894.

per pound of hard screenings where about 8,000,000 watts were generated, running full twenty-four hours, as against the report which claims only 30 watt-hours per pound of soft coal, the total output being less than 60,000 watts and the service being furnished only seven hours. The best reports do not compare favorably with the results secured in generating power for manufacturing purposes.

In order to facilitate this comparison, we have prepared a table based on 90 per cent. mechanical efficiency in the engine and the same efficiency in the dynamo:

Then $\frac{746 \times .90 \times .90}{\text{coal per hour}}$ = Watt-hours per pound of coal. And

Coal per hour per 1 H. P.	Watt hours per lb. of coal.
1.5 lbs. should produce	402.84
2 " " "	302.13
3 " " "	201.42
4 " " "	151.06
5 " " "	120.85
6 " " "	100.71
7 " " "	86.32
8 " " "	75.53
9 " " "	67.14
10 " " "	60.43
11 " " "	54.93
12 " " "	50.35
15 " " "	40.28
18 " " "	33.57
20 " " "	30.22

From this estimate of engine and dynamo loss, 1½ pounds of coal should produce 402.21 watt-hours. We have a report from the Chelsea Jute Mills, of Brooklyn, N. Y., covering a period of six days, where an average of 658.3 indicated horse-power was developed from a coal consumption of 1.482 pounds per indicated horse-power per hour, the load varying from 495.21 to 764.96 horse-power. This equipment consists of Corliss compound condensing engines and vertical tubular boilers. The plant was in operation 10 hours each day. The figures given cover the whole amount of fuel used, including banking, etc. The fuel used was George's Creek bituminous coal.

If our percentage of efficency is correct, and if we could have a fairly uniform electrical output, this plant ought to produce over 400 watt-hours, or double that of the most favorable report given us, more than double that of the next best report, thirteen times the efficiency of the plant making the lowest report, and between four and five times the average efficiency of the whole report.

No attempt has been made in this report to classify equipments, as was originally intended, but with the information here furnished as a basis, the work can be readily classified, additional information secured, and the original scheme of establishing an average basis of efficiency for the several lines of equipment can be carried out. We believe the tendency of the work is to encourage more careful records, which in turn assist in locating and eliminating losses, and we hope future reports by this Committee will show a much better average than 88.4 watt-hours for one pound of coal.

A DRAWBAUGH TRANSMITTER PATENT ISSUED.

Among the patents issued Feb. 20 was one for a carbon telephone transmitter to Daniel Drawbaugh on his application filed July 26, 1880. When the application was made Drawbaugh also applied for another patent on carbon transmitters which would have controlled all use of carbon, but this it will be remembered, was rejected two years ago when the Berliner patent, with which it interfered, was issued. The Drawbaugh Company appealed to the courts from the decision of the Patent Commissioner, and the case comes up for trial on March 12.

The first claim of the present patent is as follows:

> In a telephone transmitter, a diaphragm carrying two resistance varying electrodes electrically insulated from each other, in combination with opposing electrodes mounted upon vibratory supports and provided with means for adjusting the initial pressure between said electrodes.

The Washington Convention would have been noteworthy, if for no other reason, from the active participation of Mr. Samuel Insull as an out-and-out central station man from Chicago, although not long ago he shaped the destinies of one of the biggest manufacturing companies. It is believed that Mr. Insull has, as usual, a shrewd idea of the right end of the business.

President Cleveland has but one predecessor in office living, but President Armstrong had the pleasure of seeing around him ex-presidents Weeks, Perry, Huntley, Morrison and Ayer, all dignified mandarins of the gold button. The presence of these gentlemen was greatly appreciated as testifying to their interest in the Association's welfare.

N. E. L. A. STANDARD RULES FOR ELECTRICAL CONSTRUCTION AND OPERATION.[1]

CENTRAL STATIONS.

CLASS A.—FOR LIGHT, HEAT OR POWER.

These rules also apply to Dynamo Rooms in Isolated Plants, connected with or detached from buildings used for other purposes. Also to all varieties of apparatus of both high and low potential.

The floors of Central Stations should be cleaned thoroughly at least once a week, and especial care taken that oil is not thrown from the machinery, as floors and machinery saturated with oil increase greatly the fire risk.

Oil, waste and such supplies should not be kept in the loft or cellar, and where it is impossible to remove them to a separate building, automatic sprinklers must be installed.

Generators or Motors.

1. Must be located in a dry place.
2. Must be insulated on floors or base frames, which must be kept filled to prevent absorption of moisture, and also kept clean and dry.
3. Must not be exposed to flying or combustible materials.
4 Must each be covered with a waterproof cover when not operating.

In no case must a generator be placed in a room where any hazardous process is carried on, such as the working room of a cotton, jute, flax, woolen or flour mill.

Care and Attendance.

A competent man must be kept on duty in the room where generators are operating.

Oily waste must be kept in metal cans, and removed daily.

Conductors.

From generators, switchboards, rheostats or other instruments, and thence to outside lines, conductors:

1. Must be in plain sight.
2. Must be wholly on non-combustible insulators, such as glass or porcelain.
3. Must be separated from contact with floors, partitions or walls through which they may pass, by non-combustible insulating tubes.
4 Must be kept rigidly so far apart that they cannot come in contact.
5. Must be covered with non-inflammable insulating material sufficient to prevent accidental contact.
6. Must be ample in carrying capacity to prevent heating. (See Capacity of Wires Table.)
7. Must be connected by splices or joints equal in carrying capacity to the conductors themselves, soldered, if necessary, to make them efficient and permanent.
8. Must be, when under floors or on distributing towers, placed in spaces ample for inspection and ventilation, and provided with special insulating covering.

Switchboards.

1. Must be so placed as to make it impossible to communicate fire to surrounding combustible materials; accessible from all sides when the connections are on the back or may be placed against a brick or stone wall when the connections are entirely on the face.
2. Must be kept free from moisture.
3. Must be made of non-combustible material, or of hard wood, filled to prevent absorption of moisture.
4. Must be equipped with bars and wires in accordance with Rules 1, 2, 3, 4, 5, 6 and 7 for placing conductors.

Resistance Boxes and Equalizers.

1. Must be equipped with metal or non-combustible frames.

All rheostats for controlling dynamos, motors or devices for electric heating and cooking should be constructed entirely of non-combustible materials.

2. Must be treated as sources of heat.
3. Must be placed on the switch, or a distance of a foot from combutsible material, or separated therefrom by asbestos or cement.

Lightning Arresters.

1. Must be attached to each side of every overhead circuit connected with the station.
2. Must be in plain sight.
3. Must be on the switchboard, or in an equally accessible place, away from combustible material.
4. Must be connected with at least two earths by separate wires of large size.
5. Must be so constructed as not to maintain an arc after the discharge has passed.

Testing.

All series and alternating circuits must be tested every two hours while in operation, to discover any leakage to earth, abnormal in view of the potential and method of operation.

All multiple arc low potential systems (300 volts or less) must be provided with an indicating or detecting device, readily attachable, to afford easy means of testing where the station operates perpetually.

Data obtained from all tests must be preserved for examination by insurance inspectors.

CLASS B.—ARC (SERIES) SYSTEMS.

Outside Conductors.

All outside overhead conductors (including services):

1. Must be covered with some insulating material, not easily abraded.
2. Must be firmly secured to properly insulated and substantially built supports, all tie wires having an insulation equal to that of the conductors they confine.
3. Must be so placed that moisture cannot form a cross-connection between them, not less than a foot apart and not in contact with any substance other than proper insulating supports.
4. Must be at least seven feet above the highest point of flat roofs and at least one foot above the ridge of pitched roofs over which they pass or to which they are attached.
5. Must be protected, whenever necessary, in view of possible accidents to conductors or supports, from possibility of contact with other conducting wires or substances to which current may leak, by dead insulated guard irons or wires. Special precautions of this kind must be taken where sharp angles occur, or where any wires might possibly come in contact with electric light or power wires.
6. Must be provided with petticoat insulators of glass or porcelain. Porcelain knobs, cleats and rubber hooks are prohibited.
7. Must be so spliced or joined as to be both mechanically and electrically secure without solder. They must then be soldered to insure preservation and covered with an insulation equal to that on the conductors.

---

[1] Adopted at the Washington Convention, March 1, 1894.

Note.—These Rules are subject to amendments or alterations, and will be modified from time to time as experience and the exigencies of electrical development demand. All such changes will receive the official sanction of the National Electric Light Association, and be given immediate publicity, upon their adoption.

The following formula for soldering fluid is approved:

Saturated Solution of Zinc	5 parts.
Alcohol	4 parts.
Glycerine	1 part.

Conductors should not be run over, or attached to, buildings other than those in which light or power is being, or is to be, used, but on separate poles or structures always easily inspected.

Service Blocks.

Must be covered over their entire surface with at least two coats of waterproof paint and so maintained.

Telegraph, telephone and similar wires must not be placed on the same arm with electric light or power wires, and should not be placed on the same structure or pole.

INTERIOR CONDUCTORS.

All Interior Conductors.

1. Must be where they enter buildings from outside terminal insulators to and through the walls, covered with extra waterproof insulation and must have drip loops outside, preferably slanting upward toward the inside, and bushed with waterproof and non-combustible insulating tube.

2. Must be arranged to enter and leave the building through a double contact service switch, which will effectually close the main circuit and disconnect the interior wires when it is turned "off." The switch must be so constructed that it shall be automatic in its action, not stopping between points when started, and prevent an arc between the points under all circumstances; it must indicate on inspection whether the current be "on" or "off," and be mounted on a non-combustible base in a position where it can be kept free from moisture and easy of access to police or firemen.

3 Must be always in plan sight, never covered, except in special cases, where an armored tube may be necessary.

4. Must be covered in all cases with a waterproof and, as far as possible, non-combustible material that will adhere to the wire, not fray by friction, and bear a temperature of 150° F. without softening.

5. Must be in dry places kept rigidly apart at least ten inches, except when covered (in addition to insulation) by waterproof, non-conducting and non-inflammable tubing, which must be strong enough to protect the insulating covering from injury. Conductors thus placed may be run not less than three inches apart, and be fastened with staples, under which are placed mechanically rigid insulating strips or saddles of greater width than the metal of the staple, by which possibility of injury to the tube may be prevented.

6. Must be in damp places attached to glass or porcelain insulators, and separated ten inches or more.

7. Must be, when passing through walls, floors, timbers or partitions, treated as in central stations under like conditions.

LAMPS AND OTHER DEVICES.

Arc Lamps.

1. Must be carefully isolated from inflammable material.

2. Must be provided at all times with a glass globe surrounding the arc, securely fastened upon a closed base. No broken or cracked globes may be used.

3. Must be provided with a hand switch, also an automatic switch, that will shunt the current around the carbons should they fail to feed properly.

4. Must be provided with reliable stops to prevent carbons from falling out in case the clamps become loose.

5. Must be carefully insulated from the circuit in all their exposed parts.

6. Must be, where inflammable material is near or under the lamps, provided with a wire netting around the globe and a spark-arrester above, to prevent escape of sparks, melted copper or carbon.

Incandescent lamps in series circuits, having a maximum potential of 350 volts or over, must be governed by the same rules as for the arc lights, and each series lamp provided with a hand switch and automatic cut-out switch; when lights are in multiple series, such switches and cut-outs must not control less than a single group of lights. Electro-magnetic devices for switches are not approved.

Under no circumstances will incandescent lamps on series circuits be allowed to be attached to gas fixtures.

CLASS C.—OVERHEAD CONDUCTORS. INCANDESCENT (LOW PRESSURE) SYSTEMS.—300 VOLTS OR LESS.

Outside Overhead Conductors.

1. Must be erected in accordance with general rules for Arc (Series) Circuit Conductors.

2. Must be separated not less than six inches where they enter buildings as service conductors, and be provided with a double pole fusible cut-out, as near as possible to the point of entrance to the building, and outside the walls when practicable.

Underground Conductors.

1. Must be provided with suitable protecting devices at the ends of tube or conduit service inside the walls of buildings, as a guard against moisture and injury.

2. Must be terminated at a properly placed double pole house cut-out.

3. Must be of specially insulated conductors after leaving the tube or conduit, and separated by at least ten inches, until the double pole cut-out is reached.

Inside Wiring.

Wires should be so placed where practicable that in the event of the failure or deterioration of their insulating covering the conductors will still remain insulated.

At the entrance of every building there shall be a double pole switch placed in the service conductors, whereby the current may be entirely cut off.

Conductors.

1. Must not be of sizes smaller than No. 16 B. & S., No. 18 B. W. G., or No. 3 E. S. G.

2. Must not be paraffine covered.

3. Must not be covered with soft rubber tube.

4. Must not be laid in mouldings of any kind in damp places.

5. Must not be laid in mouldings with open grooves against the wall or ceiling.

6. Must not be laid in mouldings where less than half an inch of solid insulation is between parallel wires, and between wires and walls or ceilings.

7. Must not be laid in plaster, cement or similar finish, without an exterior metallic protection.

8. Mouldings, where admissible, must have at least two coatings of waterproof paint, to be impregnated with a moisture repellant.

Cleatwork.

1. Cleatwork is not desirable, and cleats must not be used unless in a very dry place.

2. Must not be used unless in a place perfectly open for inspection at any time.

3. Must not be used unless they are of porcelain, or well-seasoned wood, filled, to prevent absorption of moisture.

4. Must not be used unless they are so arranged that wires of opposite polarity, with a difference of potential of 150 volts or less, will be kept at least two and one half inches apart, and that where a higher voltage is used this distance be increased proportionately.

5. Must not be used unless there is a backing provided, of wood at least half an inch thick, well seasoned and filled, to prevent absorption of moisture.

Metal Staples.

1. Metal staples must never be used to fasten conductors unless provided with an insulating sleeve or saddle rigidly attached to the metal of the staple, and having such strength and surface as to prevent mechanical injury to the insulation of the conductor.

2. Must never be used to fasten conductors unless under conditions in which cleatwork would be acceptable, or where driven into a moulding specially adapted for open work.

Special Wiring.

Wherever conductors cross gas, water, or other metallic pipes, or any other conductors or conducting material (except arc light wires), they should be separated therefrom by some continuous non-conductor at least one inch. In crossing arc light wires the low tension conductors must be placed at a distance of at least six inches. In wet places an air space must be left between conductors and pipes in crossing, and the former must be run in such a way that they cannot come in contact with the pipe accidentally. Wires should be run over all pipes upon which condensed moisture is likely to gather, or which by leakage might cause trouble on a circuit.

In rooms where inflammable gases may exist, or where the atmosphere is damp, the incandescent lamp and socket should be enclosed in a vapor-tight globe. This is not to be understood to include rooms where illuminating gases are used in the ordinary manner.

In breweries, stables, dye-houses, paper and pulp mills or other buildings specially liable to moisture, all conductors, except where used for pendants:

1. Must be separated at least six inches.
2. Must be provided with a durable, moisture-proof covering.
3. Must be carefully put up.
4. Must be supported by porcelain or glass insulators.

Moisture-proof and non-inflammable tubing may be accepted in lieu of such construction.

No switches or fusible cut-outs will be allowed in such places.

Interior Conduits.

1. Must not be combustible.

2. Must not be of such material or construction that will be injured by plaster, cement, or other surrounding material, or that the insulation of the conductor will ultimately be injured or destroyed by the elements of its composition.

3. Must not be so constructed or placed that difficulty will be experienced in removing or replacing the conductors.

Must be continuous from one junction box to another or to fixtures, and of non-inflammable material, and of as substantial character as the existing gas and water pipes, in order to afford mechanical protection from injury by saws, chisels or nails.

Architects and builders should provide suitable wireways or openings in all buildings at the time of their construction, in which could be placed electric wires and conduits according to the requirements of the building.

Prior to the installation of the wires, powdered soapstone should be blown through the conduit tubes to facilitate the drawing in of the same.

4. Must not be depended upon for insulation. The conductors should be covered with moisture-proof material.

The object of a tube or conduit is to facilitate the insertion or extraction of the conductors, to protect them from mechanical injury and, as far as possible, from moisture.

Conductors passing through walls or ceilings must be encased in a suitable tubing, which must extend at least one inch beyond the finished surface until the mortar or other similar material, be entirely dry, when the projection may be reduced to half an inch.

Double Pole Safety Cut-Outs.

1. Must be placed where the overhead or underground conductors enter a building and join the inside wires.

2. Must be placed at every point where a change is made in the size of the wire (unless the cut-out in the larger wire will protect the smaller). This includes all flexible conductors. All such junctions must be in plain sight.

3. Must be constructed with bases of non-combustible and moisture-proof material.

4. Must be so constructed and placed that an arc cannot be maintained between the terminals by the fusing of the metal.

5. Must be so placed that on any combination fixture no group of lamps requiring a current of six amperes or more shall be ultimately dependent upon one cut-out.

6. Must be, wherever used for more than six amperes, or (where the plug or equivalent device is not used) equipped with fusible strips or wires, provided with contact surfaces or tips of harder material, soldered or otherwise, having perfect electrical connection with the fusible part of the strip.

Safety Fuses.

Safety fuses must be so proportioned to the conductors they are intended to protect that they will melt before the maximum safe carrying capacity of the wire is exceeded.

All fuses, where possible, must be stamped, or otherwise marked, with the number of amperes equal to the safe carrying capacity of the wire they protect.

All cut-out blocks when installed must be similarly marked.

The safe carrying capacity of a wire changes under different circumstances, being about forty per cent. less when the wire is closed in a tube or piece of moulding than when bare and exposed to the air, when the heat is rapidly radiated. It must be clearly understood that the size of the fuse depends upon the size of the smallest conductor it protects, and not upon the amount of current to be used on the circuit. Below is a table showing the safe carrying capacity of conductors of different sizes in Birmingham, Brown & Sharpe and Edison gauges, which must be followed in the placing of interior conductors.

Brown & Sharpe.		Birmingham.		Edison Standard.

14	10	14	15	8	15
16	5	16	10	5	10
		18	5	3	5

Switches.

1. Must be mounted on moisture-proof and incombustible bases, such as slate or porcelain.

2. Must be double pole when the circuits which they control are connected to the fixtures attached to gas pipes, and when six amperes or more are to pass through them.

3. Must have a firm and secure contact, must make and break readily, and not stick when motion has once been imparted by the handle.

4. Must have carrying capacity sufficient to prevent heating above the surrounding atmosphere.

5. Must be placed in dry accessible places and be grouped, as far as possible, being mounted, when practicable, upon slate or equally indestructible backboards.

Motors.

1. In wiring for motive power, the same precautions must be taken as with the current of the same volume and potential for lighting. The motor and resistance box must be protected by a double pole cut-out, and controlled by a double pole switch.

Arc Lights on Low Potential Circuits.

1. Must be supplied by branch conductors, not smaller than No. 12 B. & S. gauge.

2. Must be connected with main conductors only through double pole cut-outs.

3. Must be furnished only with such resistances or regulators as are enclosed in non-combustible material, such resistances being treated as sources of heat.

4. Must be supplied with globes protected as in the cases of arc lights on high potential circuits.

Fixture Work.

1. In all cases where conductors are concealed within, or attached to, fixtures, the latter must bo insulated from the gas pipe system of the building by an insulating joint, the material of which shall not be affected by gas or changes of temperature.

2. When wired outside, the conductors must be so secured as not to be cut or abraded by the pressure of the fastenings or motion of the fixtures

3. All conductors for fixture work must have a waterproof insulation that is durable and not easily abraded, and must not in any case be smaller than No. 16 B. & S., No. 18 B. W. G., or No. 3 E. S. G.

4. All burrs or fins must be removed before the conductors are drawn into a fixture.

5. The tendency to condensation within the pipes must be guarded against by sealing the upper end of the fixture.

6. No combination fixture in which the conductors are concealed in a space less than one-fourth inch between the inside pipe and the outside casing will be approved.

7. Each fixture must be tested for possible "contacts" between conductors and fixture, and for "short-circuits" before the fixture is connected to its supply conductors.

8. The ceiling blocks of fixtures should be made of insulating material.

Electric Gas Lighting.

Where electric gas lighting is to be used on the same fixture with the electric light.

1. No part of the gas piping or fixture shall be in electrical connection with the gas lighting circuit.

2. The wires used with the fixture must have a non-inflammable insulation, or, where concealed between the pipe and shell of the fixture, the insulation must be such as is required for fixture wiring for the electric light.

3. The whole installation must test free from "grounds."

4. The two installations must test perfectly free of connection with each other.

Pendants and Sockets.

No portion of the lamp socket exposed to contact with outside objects must be allowed to come into electrical contact with either of the conductors.

Cord Pendants.

1. Must be made of conductors, each of which is composed of several strands insulated from the other conductor by a mechanical separator of carbonizable material, and both surrounded in damp places with a moisture-proof and a non-inflammable layer.

2. Must be protected by insulating bushings where the cord enters the socket.

3. Must be so suspended that the entire weight of the socket and lamp will be borne by knots above the point where the cord comes through the ceiling block or rosette, in order that the strain may be taken from the joints and binding screws. All sockets used for wire or cord pendants should have openings at least equal to one-quarter inch gas-pipe size.

4. Must be allowed to sustain nothing heavier than a four-light cluster, and in such a case special provision should be made by an extra heavy cord or wire, as a mechanical reinforcement.

5. Must be equipped with keyless sockets, as far as practicable, controlled by wall switches. In no case may a lamp giving more than fifty candle-power be placed in a key socket on a flexible pendant.

Electrical Heating and Cooking.

In general the same precautions should be taken in the installation and operation of electric heating and cooking appliances as are applicable to circuits for electric light and power.

The practice of attaching heating and cooking appliances to lamp sockets is to be deprecated. Proper circuits must be provided, fully protected by double pole safety fuses and switches, and the appliances themselves should be kept from contact with inflammable materials.

Flexible cords should be used with strands separately covered with non-inflammable insulation, and both wires or strands covered with a waterproofing, and that by a braiding, and especial care should be taken to make proper connections on all appliances, and each should be plainly marked with the maximum volts and amperes they will safely carry.

CLASS D.—ALTERNATING SYSTEMS. CONVERTERS OR TRANSFORMERS.

Converters.

1. Must not be placed inside of any building, except the Central Station, unless as hereinafter provided.

2. Must not be placed in any but metallic or non-combustible cases, which cases should be connected to earth.

3. Must not be attached to the outside walls of buildings unless separated therefrom by substantial insulating supports.

4. Must not be placed in any other than a dry and convenient location (which can be secured from opening into the interior of the building, such as a vault), when an underground service is used.

5. Must not be placed without safety fuses at the junction between main and service conductors, and safety fuses in the secondary circuits where they will not be affected by the heat of the converter.

Primary Conductors.

In those cases where it may not be possible to exclude the transformers and primary wires entirely from the building, the following precautions must be strictly observed:

1. The transformer must be located at a point as near as possible to that at which the primary wires enter the building.

The primary lead of a transformer should be heavily insulated with the highest class insulation, such as vulcanized pure india-rubber of the best quality, preferably covered with a high class outer covering, and such leads should have a minimum length of eighteen inches.

2. Between these points the conductors must be heavily insulated with a coating of moisture-proof material, and in addition must be so covered and protected that mechanical injury to them or contact with them shall be practically impossible.

3. The primary conductors, if within a building, must be furnished with a double pole switch, and also with a double pole cut-out where the wires enter the building, or where they leave the main line on the pole or in the conduit. These switches should, if possible, be enclosed in secure and fire-proof boxes outside the building.

4. The primary conductors, when inside a building, must be kept apart at least ten inches, and at the same distance from all other conducting bodies.

Secondary Conductors.

The conductors from the secondary coil of the transformer to the lamps, or other translating devices, must be installed according to the rules for "Inside Wiring" for "Low Potential Systems."

CLASS E.—ELECTRIC RAILWAYS.

Power Stations.

All rules pertaining to arc light wires and stations shall apply (so far as practicable) to street railway power stations and their conductors.

Railway Systems with Ground Return.

Electric Railway systems in which the motor cars are driven by a current from a single wire, with ground or floor return circuit, are prohibited, except as hereinafter provided:

1. When there is no liability of other conductors coming in contact with the trolley wire.

2. When the location of the generator is such that the ground circuit will not create a fire hazard to the property.

3. When an approved automatic circuit breaker, or other device that will immediately cut off the current in case the trolley wires become grounded, is introduced in each circuit as it leaves the power station. This device must be mounted on a fire-proof base, and be in full view of the attendant.

Trolley Wires.

1. Must be no smaller than No. 0 B. & S. copper, or No. 4 B. & S. silicon bronze, and must readily stand the strain put upon them when in use.

2. Must be well insulated from their supports, and in case of the side or double pole construction, the supports shall also be insulated from the poles immediately outside the trolley wire.

3. Must be capable of being disconnected at the power house, or of being divided into sections, so that, in case of fire on the railway route, the current may be shut off from the particular section and not interfere with the work of the firemen in extinguishing the flames. This rule also applies to feeders.

4. Must be safely protected against contact with all other conductors.

Car Wiring.

All wires in cars must be run out of reach of the passengers, and shall be insulated with a waterproof insulation.

Lighting and Railway Power Wires.

Lighting and power wires must not be permitted in the same circuit with trolley wires with a ground return, except in street railway cars, car houses and power stations. The same dynamo may be used for both purposes, provided the connection from the dynamo for each circuit shall be a double pole switch so arranged that only one of the circuits can be in use at the same time.

Any electric railroad employing a ground return shall under no circumstances take its circuits into any building for light, power or other purposes, save in the case of the power and car-houses of the company.

Where light or power is supplied from the railway circuits employing a ground return for use in the power house or car house of the company, only the highest class of approved insulated wire must be used, the same to be supported on insulators and readily accessible at all times. Inflammable mouldings or casing concealing the wires must not be used.

CLASS F.—BATTERIES.

Primary or Secondary Batteries.

Secondary batteries or accumulators should be placed in a light and well-ventilated place, preferably upon racks, and thoroughly well insulated.

Frequent examinations should be made of the connections and the specific gravity of the solution.

When current for light and power is taken from primary or secondary batteries, the same general regulations must be observed as apply to such wires fed from dynamo generators developing the same difference of potential.

CLASS G.—MISCELLANEOUS.

1. The wiring in any building must test free from "grounds" before the current is turned on. This test may be made with a magneto-bell that will ring through a resistance of 20,000 ohms where currents of less than 250 volts are used.

2. No ground wires for any purpose may be attached to gas pipes within the building.

3. All conductors connecting with telephone, district messenger, burglar alarm, watch clock, electric time and other similar instruments, must, if in any portion of their length they are liable to become crossed with circuits carrying current for light or power, be provided near the point of entrance to the building with some protective device which will operate to shunt the instruments in case of a dangerous rise of potential, and will open the circuit and arrest an abnormal current flow. Any conductor normally forming an innocuous circuit may become a source of fire hazard if crossed with another conductor through which it may become charged with a relatively high pressure.

UNIVERSITY OF MINNESOTA.

MR. MORGAN BROOKS, president and general manager of the Electrical Engineering Co. of Minneapolis, Minn., delivered a lecture recently before the professors and students of the Engineering Department of the University of Minnesota, on the Telephone, showing its development from smallest beginnings to its present perfection. The lecture was an able and interesting one.

SEVENTEENTH CONVENTION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION, WASHINGTON, D. C.

The Seventeenth Convention of the National Electric Light Association was held at the Grand Army of the Republic Hall, on Pennsylvania avenue, Washington, D. C., February 27 and 28, and March 1st, 1894.

Prest. Elect. Francisco. Secretary Porter. Retiring Prest. Armstrong. First Vice-Prest. Wilmerding.

(*From a Photograph by Prince, of Washington, D. C.*)

The following were in attendance:

Altoona, Pa.:—J. P. Graham; E. B. Greene; W. Markland.

Anniston, Ala.:—H. W. Sexton.

Atlanta, Ga.:—H. J. Edgar.

Baltimore, Md.:—E. E. Ries; P. H. Alexander; H. Kent McLay; C. R. Young; Hugh Pattison; C. Edwards; J. Frank Morrison; H. A. Rowland; L. Duncan; S. Reber; D. E. Evans; P. Kielholtz; W. F. Banfield; S. Childs; G. E. Cox; W. C. Darrell; C. R. Durling; E. B. Gawthrop; C. C. Hughes; G. R. Holmes; A. B. James; F. H. Knox; C. E. Phelps; C. P. Poole; John Powell; A. L. Reese; F. Thomas; F. Del Torre; W. W. Donaldson; Mr. Smith.

Battle Creek, Md.:—J. B. Foote; J. R. Galloway.

Beverly, Mass.:—Louis McLaughlin.

Boston, Mass.:—F. W. Brigham; Capt. Wm. Brophy; David J. Cartwright; Isaac Davis; H. P. Hall; C. I. Hills; W. S. Hill; A. L. Holden; J. H. Mason; J. M. Orford; J. L. Lucas; D. R. Urquhart; Geo. H. Poor; C. B. Price: E. A. Record; A. C. Shaw.

Brattleboro, Vt.:—F. Taft.

Bridgeport, Conn.:—W. C. Bryant; C. E. Carpenter; H. A. Hubbell; T. M. Field.

Bristol, Pa.:—C. E. Scott.

Brooklyn, N. Y.:—W. S. Barstow; T. E. Crossman; J. Ferguson; E. F. Peck; L. K. McLaughlin.

Buffalo, N. Y.:—J. J. Flavin; J. F. Kester; C. R. Huntley; F. P. Little; F. H. Williams.

Camden, N. J.:—Hon. E. A. Armstrong; J. J. Burleigh; John W. Lyell; W. E. Harrington; J. R. Williams.

Cincinnati, O.:—J. A. Cabot; C. E. Jones; E. A. Sarran.

Cedar Rapids, Ia.:—W. J. Greene.

Champaign, Ill.:—B. F. Harris.

Chicago Ill.:—Edw. Caldwell; George G. Carter; Ernest L. Clark; W. F. Collins; L. K. Comstock; E. A. Cummings; Fred. DeLand; W. J. Ferris; J. H. Gates; C. E. Gregory; A. W. Harvey; P. H. Hoover; Samuel Insull; F. S. Kenfield; H. S. Manning; Geo. A. McKinlock; J. B. O'Hara; F. L. Perry; E. L. Powers; G. L. Reiman; J. H. Shay; M. J. Sullivan; B. E. Sunny; Edward Stockwell; F. S. Terry; F. Todd; C. H. Wilson; C. H. Wilmerding; M. M. Wood.

Cleveland, Ohio:—G. R. Lease; G. M. Hoag; E. B. Merriam; W. Wason.

Cuyahoga Falls, Ohio:—E. L. Babcock; C. A. Babcock.

Detroit, Mich.:—Hon. E. F. Phillips.

Eau Claire, Wis.:—G. B. Shaw.

Elizabeth, N. J.:—E. H. Bennett, Jr.

Evansville, Ind.:—C. P. White.

Fitchburg, Mass.:—A, H. Kimball,

Frederick, Md.:—A. L. Bosley.

Halifax, N. S.:—C. A. Starr.

Harrisburg, Pa.:—W. E. Groff.

Harrison, N. J.:—A. D. Page; W. S. Howell.

Hartford, Conn.:—J. J. Gates; C. T. Hills; C. E. Newton; Alfred H. Pease; C. L. Tolles.

Hazleton, Pa.:—A. Markle.

Jackson, Mich.:—W. A. Foote.

Kansas City, Mo.:—E. R. Weeks.

Lynn, Mass.:—S. F. Pritchard.

Little Rock, Ark.:—J. A. Van Etten.

Manchester, Conn.:—T. C. Perkins.

Memphis, Tenn.:—W. W. Carnes.

Minneapolis, Minn.:—A. M. Robertson.

Montgomery, Ala:—A. E. Worswick.

Nashville, Tenn.:—G. T. Brown.

Newark, N. J:—R. O. Heinrich; C. O. Baker, Jr.; R. B. Cissel; C. H. McIntire; F. N. Crane; E. Weston.

New Britain, Conn.:—T. H. Brady.

New Brunswick, N. J.:—A. J. Jones.

Newton, Mass.:—Waldo A. Learned.

New Haven, Conn.:—C. T. Hague.

New York:—H. C. Adams; L. R. Alberger; E. P. Atkinson; R. H. Beach; T. Beran; Wm. Bracken; Capt. W. L. Candee; Louis Cassier; S. H. Chase; Frank H. Clark; S. L Coles; F. R. Colvin; R. B. Corey; G. H. Coulthurst; W. F. D. Crane; Chas. Cuttriss; H. M. Davis; Frank De Ronde; Chas. D. Doubleday; C. T. Eshburn; H. A. Foster; Henry W. Frye; N. W. Gage; Geo. E. S. Greeley; B. E. Greene; S. D. Greene; J. P. Hall; Newton Hall; W. J. Hammer; W. T. Hunt; H. G. Issertel; G. J. Jackson; W. J. Johnston; E S. Keefer; A. H. Kimball; A. A. Knudson; H. Ward Leonard; C A. Learned; F. H. Leonard; Romaine Mace; F. A. Magee; Geo. T. Manson; T. C. Martin; G. G. McDuff; J. McGhie; P. L McLaren; P. W. Mitchell; George T. Moore; T. J. Murphy; W. J. Newton; W. F. Osborne; F. B. Parsons; A. H. Patterson; J. C. Pierrez; G. M. Phelps; H. W. Pool; Geo. F. Porter; Chas. W. Price; C. Ransom; H. D. Reed; H. T. Richards; F. A. Scheffler; A. L. Searles; J. A. Seely; E. W. Seymour; C. D. Shain; R. L. Shainwald; Chas. A. Schieren, Jr.; H. L. Shippey; H. J. Smith; J. E. Smith; Louis Stirn; Robt. Stewart; G. R. Stetson; L. Stieringer; C. E. Stump; H. M. Swetland; F. Taylor; F. B. Thilow; D. Thomson; J. H. Vail; J. Van Vleck; C. S. Van Nuis; C. T. Waugh; W. D. Weaver; B. R. Western; Jos. Wetzler; S. S. Wheeler; G. L. Wiley; F. H. Wilkins; E. E. Wood; Jos. Wright; G. Kirkegaard; J. Elliott Smith; W. F. Hanks; L. B. Marks; H. L. Lufkin; Louis E. Howard; C. J. Field; Prof. George Forbes; S. A. Douglass.

Northeast, Pa.:—John R. Coffman.

Norfolk, Va.:—Jas. L. Belote; W. W. Chamberlain.

Ogdensburg, N. Y.:—J. H. Findley.

Olean, N. Y.:—George Tobes.

Paterson, N. J.:—Wm. M. Brock; J. Noonan.

Parkersburg, W. Va.:—C. C. Martin.

Philadelphia:—W. Annear; J. Appleton; Sanford Belyen; C. E. Bibber; J. G. Biddle; C. A. Bragg; H. J. Buddy; Henry Clay; H. A. Cleverly; H. B. Cutter; F. W. Darlington; A. J. De Camp; F. R. Ford; J. C. Gardiner; Felix Haac; J. S. Hinds; H. G. Kellogg, Jr.; J. R. Lovejoy; A. H. Manwaring; A. J. Martin; J. McLeer; J. A. Pentz; Eugene Richter; P. G. Salom; T. Carpenter Smith; N. D. Webster; J. R. Williams; E. W. Wilkins; E. T. Wilkinson; E. G. Willyoung; W. B Wood; Peter Wright; G. A. Vallee; Thos. Spencer; R. B. Smith; James Garnett; G. H. Fisher; W. S. Andrews.

Pittsburgh, Pa.:—O. H. Baldwin; G. H. Blaxter; J. S. Crider; A. Groetzinger; Ernest H. Heinrichs; J. W. Marsh; M. Mead; C. Townley; C. F. Scott; L. B. Stillwell; N. A. Vandervort; A. J. Wurts; F. H. Tooker.

Portland, Me.:—Geo. W. Brown.

Providence, R. I.:—M. J. Perry.

Ravenna, Ohio:—C. L. Rodman.

Richmond, Va.:—Thos. W. Brander; Maurice Hunter; Maurice W. Thomas.

Rochester, N. Y.:—F. M. Hawkins; Geo. A. Redman; C. F. Burns.

Rockford, Ill.:—M. A. Beal.

Rutland, Vt.:—M. J. Francisco.

Salem, O.:—Joel Sharp; D. L. Davis; G. A. Barnard.

Savannah, Ga.:—T. P. Keck.

Schenectady, N. Y.:—A. B. Herrick.

Springfield, Mo.:—W. H. Fellows.

Steubenville, Ohio:—Joseph Gwynn.

St. Louis, Mo.:—J. I. Ayer; Louis Nahm; J. H. Rhotehamel.

Swissvale, Va.:—C. F. Ellis.

Syracuse, N. Y.:—H. J. Gorke; J. L. Hinds; W. J. Morrison; A. P. Seymour.

Taunton. Mass.:—O. L. Mitchell.

Toledo, O.:—C. R. Faber, Jr.

Toronto, Ont.:—Frederick Nicholls.

Trenton, N. J.:—J. T. Ridgeway.

Vineland, N. J:—Prof. W. A. Anthony.

Warren, O.:—B. B. Downs; W. D. Packard.

Washington, D. C.:—C. H. Bowen; F. G. Bolles; Geo. S. Boudinot; A. W. Clapp; Prof. O. Dodge; Hon. A. C. Durborow, Jr.; Allen R. Foote; M. D. Law; Geo. C. Maynard; Robert Watson; A. Young; J. R. Ash; J. Burkett; C. F. Chrisholm; F. H. Clarke; G. G. Dennison; S. Q. Hayes; J. D. McIntire; Prof. Mendenhall; F. D. Neale; Chas. Pardoe; Wilmot Lake.

Waterbury, Conn.:—Alden M. Young.

West Chester, Pa.:—J. E. Pyle.

Wheeling, W. Va.:—E. Buchman; H. H. Dunlevy; E. M. Holliday.

Wilkinsburgh, Pa.:—John J. Jennings.

Wilmington, Del.:—C. R. Van Trump; F. D. Sweeter; W. Shaw.

Worcester, Mass.:—H. H. Fairbanks.

Youngstown, O.:—R. P. Holmes.

The following ladies were in attendance:

Mrs. W. A. Anthony; Miss E. W. Armstrong; Mrs. C. O. Baker, Jr.; Mrs. C. E. Bibber; Mrs. C. A. Bragg; Mrs. J. J. Burleigh; Mrs. Willard A. Candee; Miss Candee; Mrs. Louis Cassier; Mrs. H. E. Cooke; Mrs. Wm. Cooney; Miss Cumming; Mrs. A. J. De Camp; Miss DeCamp; Mrs. L. A. Doud; Mrs. H. A. Foster; Mrs. James Ferguson; Mrs. M. J. Francisco; Mrs. W. J. Hammer; Mrs. H. G. Issertel; Mrs. W. J. Johnston; Miss Johnston; Mrs. Romaine Mace; Mrs. Geo. T. Manson; Mrs. A. H. Manwaring; Mrs. G. A. McKinlock; Mrs. Orford; Miss Morris; Mrs. J. Noonan; Mrs. A. H. Paterson; Mrs. E. F. Peck; Miss Essie Read; Mrs. E. W. Seymour; Mrs. R. L. Shainwald; Miss Bessie Shütte; Mrs. H. J. Smith; Mrs. M. J. Sullivan; Mrs. F. D. Sweeter; Mrs. H. M. Swetland; Mrs. Schuyler S. Wheeler; Mrs. J. Wright; Miss Vail; Mrs. G. A. Vallee.

TUESDAY MORNING SESSION.

PRESIDENT ARMSTRONG, of Camden, in calling the convention to order and welcoming the members, said he might be counted remiss did he fail to congratulate them specifically as well as generally. The past year had been a very trying one on electrical enterprises. As they were among the settled businesses of the country, the newest and therefore the most elastic, they had felt the financial stringency worse than many others, but they had not been without cheer and encouragement during it all. Figures from the most reliable sources, show that there are now upward of 2,300 central stations in this country, representing at least two hundred millions of capital. Involved in electrical manufactures and supplies of various kinds, are as many millions more; this employing as it naturally does hundreds of thousands of men, supporting hundreds of thousands of homes, adding to the material wealth, prosperity and happiness of our people, made them, as representatives, trustees of a great and responsible trust. There had been a tendency in the last few months, however, toward a revival, largely instigated, he thought, by the representatives of our large manufacturing corporations, of the agitation of municipal ownership of electrical light plants. He sincerely believed that to be a bad policy for the city, as he had always maintained. He believed it to be a worse policy for the manufacturing concerns that advocate it. But no city could ever afford to do an unfair thing. Municipal ownership had been somewhat more earnestly revived in his section of late, than it had been for many years, and he read an editorial from the *Philadelphia Public Ledger*, upon this question, advocating careful consideration, and fairness to existing companies by municipalities. He strongly advocated concerted action in cases of this kind. Financially the association was in admirable condition; its debts all paid and money in the treasury.

A letter of regret was read from Col. Thurber, Secretary to President Cleveland, stating that owing to the absence of the President from the city, it would not be possible for him to meet the delegates. Mrs. Cleveland also regretted her inability to meet the ladies accompanying the gentlemen in attendance upon the convention.

Mr. E. J. Hall, Vice-President and General Manager, tendered the delegates the use of a Long Distance telephone which had been specially put in on the ground floor of the Ebbitt House, by the Long Distance Telephone Company. President Stevenson, of the Metropolitan Railroad Company, of Washington, issued complimentary tickets good on the cars of his company, to those in attendance at the convention. The Cosmos Club, of Washington, extended the courtesies of its club-house to the delegates. On motion, a vote of thanks was tendered for the above courtesies.

Letters of regret at their inability to be present were read from the following gentlemen: Thomas A. Edison; George Westinghouse, Jr.; Nikola Tesla; Chas. A. Coffin; Thos. D. Lockwood; Prof. E. L. Nichols, of Ithaca; Prof. Henry T. Bovey, of Montreal; Gen. Charles L. Knapp, of Montreal; Elihu Thomson, Lynn, Mass.

THE PRESIDENT announced the next order of business to be the

REPORT OF THE COMMITTEE ON LEGISLATION.

MR. C. H. WILMERDING, Chairman, of Chicago, regretted that his Committee had no formal report to make. Since his appointment as Chairman of the Committee no important information had reached them in regard to legislation affecting electric light interests, although there has been a great deal of that sort of legislation threatened.

MR. W. J. MORRISON, of Syracuse, said he was informed that there was a bill now pending before the Legislature of the State of New York authorizing the Board of Water Commissioners of any incorporated village in that State, having a water works system belonging to the village, to establish a lighting system within said village for the purpose of supplying light, by means of gas, electricity or other approved system, to the inhabitants of said village. It was a matter, he thought, which deserved the attention of the Association in some form.

MR. HUNTLEY and **MR. DE CAMP** thought the Committee ought to be discharged as being too large, and a smaller one appointed.

MR. CLAY, of Philadelphia, suggested that the Association employ a competent person to compile the electric legislation of the several States.

MR. SAMUEL INSULL, of Chicago, thought the functions that should be performed by the Committee on Legislation should rather be that of preventing legislation detrimental to the members, than compiling legislation that was past.

MR. STETSON, of New Bedford, Mass., said that in his state they employ a competent attorney who watches the proceedings all the time.

On motion the resolution of Mr. Clay was referred to the Executive Committee, to report thereon.

THE PRESIDENT announced the next report in order to be that of the Committee on Finance. **MR. JOHN A. SEELY**, the chairman, read the report, which showed the finances to be in satisfactory condition. On motion the report was accepted and ordered to be filed.

The next order of business announced was the Report of the Committee on Relation between Manufacturing and Central Station Companies, Mr. Frederick Nicholls, of Toronto, Chairman. The report was postponed to be discussed in executive session.

THE PRESIDENT then introduced Dr. Richard J. Gatling, the inventor of the Gatling gun, who addressed the Convention briefly.

MR. W. J. HAMMER referred to the high rates of postage on society publications and suggested that the National Electric Light Association appoint a committee to present a protest in this matter. **THE PRESIDENT** appointed Messrs. Adams, Young and Gwinn such a committee.

TUESDAY AFTERNOON SESSION.

THE PRESIDENT called the meeting to order at 2.30 p. m.

MR. M. J. FRANCISCO moved that Vice-President A. E. Stevenson be invited to attend the sessions and that a committee be appointed to notify him. **THE PRESIDENT** appointed Mr. Francisco and the members of the Reception Committee, as such committee, to include Messrs. Baker and Seely.

The President announced the first business of the afternoon session to be the **REPORT OF THE COMMITTEE ON DATA**,[1] which was read by **MR. H. M. SWETLAND**, of New York, Chairman.

MR. SWETLAND added that the did not secure reports from the best stations, and that the average might have been lowered materially. He also pointed out that of two thousand inquiries sent out they received replies from something like eight hundred, and less than one hundred suitable for their purpose. This report seemed to develop one idea, and that is, the necessity of more accurate records in central stations.

MR. BURLEIGH thought seven pounds of coal per horse power hour far from a fair average. **MR. NICHOLLS** thought the result of the collection of this data went to show that electric light plants must be singularly inefficient.

MR. J. H. VAIL, of New York, believed that in order that a report of this kind should be fully understood, it should give a classification of the equipments, and of the quantity of the coal. The 88.4 watt-hours per pound of coal equalled about seven pounds of coal per h. p. per hour. He knew of a large number of stations, probably a hundred, running about on that basis, and fifty other stations which were producing a horse power hour for four pounds of coal, and had been doing it for several years. Other stations of recent construction were producing a horse power hour for an average of two pounds of coal.

MR. T. CARPENTER SMITH as the result of his experience believed that any station using ordinary engines non-condensing, non-compound and doing it on seven pounds of coal per horse power hour, including banking and perhaps running on an economical load six or seven hours in the evening was doing very well. The report gave the average. The majority of these stations could be very much improved with a little extra care. He thought a great many of the members did not reply to the circular, with the idea that it was giving away their business. The Committee wanted it clearly understood that nothing of that kind was involved. The returns are tabulated and then buried.

MR. VAN TRUMP, of Wilmington, Del,, believed that with a station that is burning three pounds of coal per indicated horse power per hour, it was impossible to get 201 watts on the line. He did not think any central station engineer who is running on three pounds of coal could get more than 186 watts out on his line, from which these results are tabulated. **MR. SWETLAND** agreed that the 90 per cent. of efficiency in the dynamo meant directly at the machine; and no loss by resistance in the wire on the circuit was taken into consideration.

THE PRESIDENT called for the **REPORT OF THE COMMITTEE ON UNDERGROUND CONDUITS AND CONDUCTORS**. None having been prepared the committee was discharged.

THE PRESIDENT announced the next order of business to be the **REPORT OF THE COMMITTEE ON RULES FOR SAFE WIRING**.[2] Copies of the report of the Committee were distributed but the discussion was postponed until Thursday morning.

MR. W. E. HARRINGTON then read a paper on **FAULTS INCIDENT TO THE PROTECTION OF LIGHTING AND POWER CIRCUITS**.[3]

MR. WHITE, of Evansville, Ill., in answer to questions stated that he had used magnetic cut-outs inside his station on a 2,000 volt 25 ampere alternating circuit for three years.

MR. W. J. HAMMER described the Cunningham mercury cup magnetic cut-out used by Swinburn in his high tension experiments.

MR. ROBERTSON, of Minneapolis, had had considerable trouble with fuse wires on his alternating circuits but since the introduction of magnetic cut-outs he had had no trouble. He had been looking for a device in the nature of a magnetic cut-out which would do away with fuses. He found it at last and had been using a magnetic cut-out on his five hundred volt power circuit and it had never failed to act in time to save a machine.

MR. WHITE had found it a most efficient protection against

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed, and drafts, checks and post-office orders made payable to the order of* The Electrical Engineer. *Communications for the attention of the editors should be addressed,* Editor of The Electrical Engineer, 203 *Broadway, New York City.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

CONVENTION THEMES.

If any doubts have existed as to the continued interest taken in the proceedings of the National Electric Light Association they will be dispelled by the record of the meeting which we print in this issue. The most marked indication of this increasing interest is to be found in the lively discussions, and indeed, though not lacking in good papers, the Washington Convention may be said to have been pre-eminently marked by its varied and excellent discussions. Without exception the topics and papers were of an eminently practical nature and reflect great credit on Secretary Porter to whose efforts in this respect the success of the Convention was largely due.

Of the Reports, that of the Committee on Data ought to be closely studied by every station manager. While the average figure of fuel consumption in central stations, namely 7 pounds of coal per horse power hour, is based on but a small fraction of the whole number of stations in actual operation it is sufficient to indicate that there is much improvement possible in that all-important source of expense. The reports from numerous stations show what may be done in this direction, and while engineers have not yet arrived at the best figures attained in marine engine practice, they are gradually approaching the 2½ lb. limit. The Committee on Rules on Safe Wiring submitted a set of Standard Rules which will it is hoped bring order out of the somewhat chaotic state that has existed for some time owing to the conflicting rules issued by plagiarizing boards of fire underwriters in different sections of the country. The rules adopted if conscientiously carried out will leave the insurance men little basis for the repeatedly threatened increase in rates on buildings lit by electricity. That the Association's work and influence is extending is shown by the very proper reference in the new rules to electric railway construction, more particularly to those systems embodying a ground return. Perhaps the most far-reaching in its effects is that referring to the non-admission of electric railway circuits for any purpose whatever to buildings other than the power and car houses of railway companies. While the rule is eminently a proper one from the standpoint of safety alone, for which it is primarily intended, its effects go beyond and strike at a practice which ought, as a general thing, to be discouraged, and that is, the furnishing of light and power to private consumers by electric railway companies. Happily this class of work has not yet become general, but with the rule above mentioned enforced, it will, we hope, put an end to a business to which electric railway companies are not entitled and which, in their own interests, they ought to avoid.

As might have been expected, the members of the Association were on the *qui vive* for Mr. Huntley's report of the results obtained by him with a circuit of fifty arc lamps fitted with the Howard device for prolonging the life of the carbon. Mr. Huntley's report unfortunately did not give the many inquiring members the actual cost of operation which all were so anxious to learn, but the actual results obtained must be considered to be distinctly hopeful considering the newness of the device. The Howard lamps on exhibition both indoors and outdoors at Washington afforded a good opportunity for watching them in actual service, and their work compared very well with that of the usual open arc. The latest development of this work to which we alluded in our last issue and which was brought before the convention by Mr. L. B. Marks, that is, the high potential arc, makes it evident that we have not heard the last of this new method, and the next convention will probably give us the figures which were so ardently clamored for. That arc lighting from the commercial standpoint is by no means inactive was demonstrated by the truly remarkable statements of facts and figures brought out during the discussion on arc lamps on incandescent circuits. If the operators of central stations distributing current at low potential are still in doubt as to what can be done in the way of increasing their profits, the record of the work accomplished by Mr. Barstow in Brooklyn, with 2,700 already installed and 400 more ordered ought to be sufficient. We must confess that we hardly expected to find the showing so good but the reasons for the increased economy of running arc lamps from incandescent circuits leave no room for questioning the accuracy of the statements made. Principal among these is probably the fact that, as shown in one instance at least, current can be manufactured and delivered to the low tension main at 25 per cent. less cost than to a high potential circuit. This of course is primarily due to the fact that thus far arc light machines have barely exceeded 100 h. p. in capacity while there appears to be no practical limit, so far as power is concerned, to the construction of low potential machines. To this must be added the superior efficiency of the low tension machines and the less care required by them.

This also brings us to another question discussed at the meeting, namely, "The Most Economical Size of Arc Machine." But one opinion seemed to prevail as to the expediency of employing the largest machines the manufacturers would guarantee. Unfortunately the limitations of insulation will prevent the attaining of arc machines much over the present largest sizes, and even if Prof. Crocker's 10,000 volt machines should become commercially available they would only bring the maximum capacity up to 200 arcs for a single machine.

It was humiliating indeed to hear on the floor of the Convention the admission that American arc lamps do not compare well with those abroad on the score of steadiness, and that the fault does not lie in the mechanism, but in the quality of the carbons employed. This is all the more humiliating as it is difficult to conceive a combination of circumstances more favorable to the production of good and cheap carbons than those which obtain in this country. We have the coke of the oil stills, practically a by-product, and close at hand the natural gas to heat the furnaces. There are thus but two explanations possible for the failure of American manufacturers to produce good carbons,—either they do not know how, or, if they do, sufficient care is not exercised in the manufacture. Neither of these reasons, however, is excuse or adequate explanation for the present condition of affairs and it is such cases as these that make us sigh for a little temporary free trade. We have little doubt that with carbons on the free list, those of our own manufacture would soon drive any of foreign make out of the market on every point of advantage.

Of the papers read at the Convention that of Mr. Charles F. Scott particularly opens up a new field and adds a new chapter to the controversy between the two and three phase advocates. It is a chapter of peace and amity, however, as Mr. Scott shows how both systems can be combined to act to the best advantage. Mr. J. H. Vail's paper also served to draw attention to a condition of affairs to which electric lighting interests should be alive, since electrolysis due to grounding of circuits is an evil but too well known to the central station manager, and has probably been as fruitful a source as any among those which have brought the electrical and the insurance interests into conflict in the past.

The discussion on "Meter vs. Flat Rates" served to bring out an undeniable preference for the meter, which is further proof of the advancing confidence of the public in electric lighting. The influence of the substitution of the meter as against the flat rate on the income of the station, instances of which were mentioned, is a matter which those managers still working on the old basis will do well to consider carefully. It is apparent that the days of the flat rate are numbered and that no regrets will be felt at its final abandonment. The relation of the customer to the central station in the matter of lamp renewals also gave opportunity for calling attention to a practice which requires guarding against where customers furnish their own lamps. It was shown how, by the customer's employing lamps of low efficiency, the current drawn from the station might be largely in excess of that which would be called for with a more economical lamp. This would seem to indicate that where the practice obtains of requiring customers to furnish their own lamps, the latter ought to be under the careful observation of the lighting company, as indeed is the case in most instances. Every company should encourage the use of high efficiency lamps.

In the matter of station economy Mr. Edward Weston in the discussion of Mr. A. B. Herrick's valuable paper, drew attention to the electric losses which may occur right within the station when the current output is heavy, and which ought to make station managers look carefully to the character of joints on the switchboard, as well as to the character of their station instruments.

On the whole the convention was a great, an even remarkable, success. It showed the Association to be more useful, more influential, more prosperous than ever. It has now rallied to its support the old low-tension direct current element that once avoided its meetings; it has broadened its field of work; it has reached out, legitimately, on one side to electric heating and cooking and on the other hand to electric railway work. One of these fine days we shall have the electric light and street railway associations meeting together by pre-arrangement at the same time and place, for co-operation and mutual support. More than one of the members of the N. E. L. A. who have watched its career from the beginning have been gratified at this Washington meeting to observe how substantial and dignified has become the nature of its membership and attendance, and how steadily year by year the general character of its work gains in value. But it must now go out to draw in a larger membership, until like other kindred associations it can boast of as much as 25 or 30 per cent of the operating companies as within its fold. Then the Association will be in a position for good whose strength cannot be overestimated.

lightning. This device was similar to that described by Mr. Hammer.

Mr. T. C. Smith's rule has been to begin with the lightest fuse that will carry the load, and then run it long enough to satisfy oneself that the work is all right; he then takes out every one of those fuses and puts in a fuse that will thoroughly protect the smallest wire nearly up to the carrying capacity of the wire; the blowing capacity of the fuse being just short of the carrying capacity of the wire.

Capt. Wm. Brophy, of Boston, had tested fuses and found they would become red hot before they would let go. Fuses were a broken reed on which to lean. While nearly all fuses were ready to combat with an abnormal flow of current, none of them would stop the sneaking current. The present method of classifying fuses was all wrong. The fuses may be put in a building for a ten or sixteen candle light and afterward changed for a thirty-two. Of course the same fuses would not serve.

Mr. Vail:—Magnectic cut-outs on lighting circuits have been used frequently in Schenectady works of the Edison Company in the testing of dynamos, and can be adjusted very accurately. It appears to me that there must be a difference made between the cut-outs that can be used in a central station and the cut-outs in a private house or isolated plant. In regard to the action in the fuse to which Mr. Smith referred, it is due to oxidation. The fuse is made of soft metal, and is usually placed under a binding screw of brass. The metals are different, and oxidation will in time result. The only way to prevent that, in my experience, is to have a hard metal end soldered on the fuse—such as a brass or copper tip on the fuse. If the fuse is put into position clean it will be found that the hard metal will prevent the oxidation, and no difficulty will occur in that way. Captain Brophy is undoubtedly correct in the statement he makes in regard to replacing small fuses by large fuses. I brought that to the attention of the Edison people some years ago, and I sent some inspectors to examine the central stations. I found a great many instances where circuits of six lights, which had been properly fused in the first instance, had been replaced by a fuse for thirty lights, or a ten light circuit by a forty light fuse.

Mr. Smith:—The oxidation under the heads of the fuse is not what I am afraid of. The instances I referred to always take place in the body of the fuse. It is undoubtedly due to some oxidation, which makes the skin of the metal not very destructible by the heat; but it is something new to me to hear they come that way from the manufacturer. In regard to the replacing of fuses, I happen to know of one fire that was caused by the owner of the house himself.

Mr. Hammer thought a good deal of trouble might be obviated if a three-cornered file were taken and run across the fuse. It made a weak point and caused a tendency to blow out at once if there was an overload.

Mr. J. M. Orford:—Our method of fusing is to use the simple, ordinary fuse which we buy in the market. We have magnetic cut-outs on some of our dynamos, but we use also a fuse and switchboard for each circuit, besides the magnetic cut-out to protect the dynamo. Every time we branch from the main we put in a fuse, and every time we put a converter up we put in a fuse. We find little trouble with them, except when we get to larger sizes. The capacity of a fuse is an unknown quantity. I find on the market a fuse made of aluminum, which is going to be the fuse of the future, in my opinion, because it is extremely thin, and any undue heat generated seems to melt it quickly. They stamp on each fuse its capacity.

Capt. Brophy:—I am not one of those who believe that electricity is responsible for fires; not for one atom of the fires it is made responsible for by the public. I have been in a position to investigate fires that were said to have originated in electric current, and not one per cent. of the fires could be traced to that cause. The percentage of fires caused by electricity has been insignificant, for years; they are usually caused by matches and kerosene.

Mr. Nicholls:—I would like to ask if any members here have had experience in measuring by meters power supplied for elevators. In starting an elevator you may use 110 volts, and 40 to 80 amperes, and after the elevator gets started this will run down to 12 or 15. Has any one had any experience in measuring this current? There was a contract awarded for operating some elevators in a government building by electric power, and the government refused to make a meter contract, and insisted upon a flat rate, because the weight of the expert evidence which they secured was to the effect that no meter at present in use would accurately record the current, with such sudden fluctuations.

Mr. Harrington:—I have had a wattmeter on street cars, which present about the same conditions, and the amount of the current recorded was so absurd—two or three amperes—that we abandoned it. The instrument would not record the fluctuations of street car work.

Mr. Carnes, of Memphis, had used such a method only upon a 500 volt current; his experience had been variable; the general result had been to discourage him from the further use of the meter in such cases.

The President then introduced **Prof. T. C. Mendenhall**, of Washington, who addressed the meeting on the subject of "Units of Electrical Measure." The speaker briefly reviewed the work in this direction accomplished by the International Electrical Congress at Chicago, and urged early action to have those electrical standards officially adopted here before they are adopted abroad. A bill had already been introduced in Congress with this object in view and the Secretary of the Treasury had been urged to approve their adoption for use in all departments of the government.

The Chicago Congress had been urged to officially define the 2,000 c. p. lamp, but agreed that the time had not yet come for this definition.

An invitation was read from the Rock Creek Railroad Co. tendering the use of its lines to the delegates. The invitation was accepted with thanks. The meeting then went into executive session.

WEDNESDAY, FEB. 28—MORNING SESSION.

The President announced the first order of business to be the paper on "The Importance of Complete Metallic Circuit for Electric Railways,"[1] which was read by Mr. J. H. Vail.

At this point a beautiful basket of flowers was placed on the platform, accompanied by a letter from the "Wives, Sisters and Sweethearts of the N. E. L. A.," expressing their thanks for the drive through the city on the previous afternoon.

In answer to a question by **Mr. Burleigh**, **Mr. Vail** said he believed that with the insulated wire bond they could get entirely clear of electrolysis in the pipes and that he did not regard a fish-plate of any permanent value at all in bonding. He had had no experience with welded rail joints, but thought there were many physical difficulties in the way which would prevent their success.

Mr. Burleigh: My reason for asking the question was that a gentleman from Boston told me a few days ago that they had perfected the system of welding rail joints, especially as they welded them on the fish-plates instead of on the rail itself.

Mr. Ch. Wason, of Cleveland, stated that the first attempts at electric rail welding in Cambridge, Mass., were not a success; but that improved methods were now being adopted. In his opinion rail bonds would never do away with electrolytic action. It must be done by a continuous rail, of the ninety pound section, which most street railroads are putting down. The joint and the wheel of the motor were the two things that street railway men had now got to contend with. If some one could get a wheel that would not wear out, and the electrically welded joint apparently looked as if it would always stand, the street railroad men would bless him.

Mr. M. D. Law, of Washington, agreed with Mr. Vail in all he had said about making his track as complete a metallic circuit as possible, but pointed out that that condition was fully met by the Love conduit trolley system operated in Chicago and Washington, described in our last issue.

Mr. C. Cuttriss, of New York, electrician of the Commercial Cable Co., spoke of the trouble experienced in the company's lines which were grounded at Coney Island, close to an electric railway system. The potential over the marshes measured higher by about one-tenth of a volt in every thirty feet. The difference kept on increasing, being from zero at the Island to eight or ten volts at New York. One could imagine what the effect of this would be on a sensitive instrument. The remedy had now been applied, but no telegraph company would be able to get a natural and pure earth again until the electric railroad systems get a metallic return instead of a ground return.

Capt. Wm. Brophy said that certain railroad companies had been introducing loops from their trolley systems to furnish light and power. He had fought that steadily, believing that it was dangerous, not to say that they were encroaching on the field that properly belonged to the electric light companies. It was unsafe to introduce loops from a grounded trolley system into any building for the purpose of furnishing light or power. The Rules which would be submitted to the meeting took strong grounds against this method of lighting. He did not believe rail welding would be a success.

Mr. T. C. Smith referred to experiments made with rails solidly butt-ended and the good results obtained. **Mr. Wason** confirmed this by his experience on a section of track in Cleveland.

Mr. Harrington believed that the best plan to overcome the difficulties is to use a solid butt with a flexible bond, with the butt welded to the rail, and do away with the imperfect contact which has usually been employed.

Mr. J. A. Seely drew attention to the desirability of having the rail lengths as long as possible. The original lengths were thirty feet; they now turn them out as long as one hundred feet.

The President announced that the subject of

STORAGE BATTERIES

was the next topic of discussion.

Mr. Wm. Bracken, of New York, opened the discussion. He said that peace now reigned over the storage battery interests in this country. The companies had come in under one flag and were united for a common interest so that one could purchase a storage battery to-day with the confidence that he was not going to be annoyed by threats of suits for infringement. He had also had the representatives of several foreign companies here this summer and gotten a great deal of useful information from them. As to the nature of the guarantees, any person desiring to install a storage battery plant in his station could readily satisfy himself as to the life of the plant. He did not think there was any company asking more than 10 per cent. for the cost of maintaining the battery. He had no doubt that experience would prove the cost of maintenance to be less.

---

[1] See page 199.

Dr. P. G. Salom, of Philadelphia, said that the question of the advisability of the use of storage batteries at the present time in central station plants was purely a commercial one. Would it pay?

In order to answer this question intelligently, the first requisite was to have a unit or standard. In other words, Given a standard engine and dynamo of the average size used in central stations, what is the cost per kilo-watt hour or ampere-hour? Having determined this cost, based on a given price for coal and labor, each central station operator can determine at the end of the year how closely he approximates this ideal cost by dividing his total output into his total operating expenses, and further by keeping careful records he can also determine what factor or factors are operating to prevent his attaining the ideal results. Having determined all these factors for his own individual case it becomes a simple question of arithmetic for him to determine whether, with an additional investment for a battery with a given output and efficiency and at a given cost for maintenance, he can advantageously add to his plant a storage battery. No hard and fast rule can be adopted. No two central stations are alike either in equipment or output, and therefore, the best size of battery equipment or proper proportion of battery to other units may never be exactly the same in any two cases. They were now prepared to give responsible guarantees that the maintenance of the battery should not exceed a certain reasonable cost per annum. He added that the life of a battery under reasonable working conditions is directly proportional to the amount of lead used in its construction. He would undertake to build a storage battery that would last one hundred years if people were willing to pay for it.

Mr. J. Appleton, Philadelphia, said the previous speakers had gone over the general ground concerning the use of storage batteries in central stations and had said what might be done. He would like to draw their attention to something that had been done in this country and which spoke for itself. He referred to the storage battery plant which the Electric Storage Battery Company who manufacture the chloride accumulator had recently installed for the Germantown Electric Light Company, and which he described, and of which he gave the following figures:

Saving on the one year's running in labor, coal, water, oil, waste, etc., not counting the decreased depreciation of machinery due to shutting down from daylight to dusk was $2,500. Besides this there was a great advantage in being able to overhaul and examine all machinery in the day time while everything was shut down. This was on the first battery installed having 800 ampere-hours capacity. This being so satisfactory and the behavior of the battery being equally good the Germantown company decided to put in a battery of 2½ times this capacity which would enable them to increase their day load and consequently increase the savings, as the cost of charging a large battery is only the extra fuel required. This larger battery was installed at the beginning of this year. The battery consists of 120 cells of the chloride type G eleven plates in each, arranged 60 on each side of the 3-wire system; the capacity of each cell is 1,000 ampere-hours or 2,000 ampere-hours with both sides; the normal rate of discharge is 200, maximum 400, and this can safely be increased in case of sudden demand or emergency. One special feature of these cells is the size of the plates, viz., 15″ x 15″.

Mr. Appleton then gave a brief outline of the battery as handled, and stated that with a properly designed and installed battery such as that at Germantown the maintenance and depreciation would not exceed that of the other portion of the central station plant. He also pointed out that outlying districts could be reached by storage battery substations, fed by high potential cnotinuous current.

Mr. Charles R. Huntley, of Buffalo, then addressed the meeting on

ARC LAMP TESTS,

embodying the results of a test of the Howard incandescent arc-light.

Mr. Huntley stated that it was not his purpose at this time to explain the merits or demerits, if there be any, of the appliance, but to give the results of his experience. He assumed absolute control of the circuit on February 4, and put it into the hands of one of his men, giving it the same care and attention that he did the forty-two circuits running from the station. They patroled the circuit at night from the hour of burning, 5.45 p. m., till 7.10 in the morning. A representative of the company was with the trimmer. The test was made originally of fifty arc lights upon a circuit, and the dynamo was a No. 8 Brush machine, of the latest type, with the following results:

> "Feb. 7; Ferry corner Grant St. out 1.10 a. m.; started itself two minutes later. Feb. 8; circuit flashed badly until 12 p. m.; started lamp Elmwood and Summer streets 9.45 by switching off and on, started same lamp 3, 4 and 5.30 a. m. Carbon burned out 3.10 a. m. Ferry and Richmond. Started Ferry and Grant 1, 2 and 3 a. m. by pulling cable. Stop on clutch too high and lowered arc spring one turn. Feb. 9, 10, 11, and 12, lamps O. K. Feb 13; put on new cylinders on four lamps. Feb. 14; lamps O. K. Feb. 15; carbons burned out of four lamps. Feb. 16; trimmed circuit, used thirty-three cylinders. Feb. 17, 18, 19 and 20, lamps all O. K., renewed fourteen cylinders and trimmed circuit. Feb. 21, 22, and 23, lamps all O. K., trimmed lamp Plymouth street, cylinder broken."

Referring to report of February 8, that night believing that they might run more lamps than the fifty lamps in the circuit, they had installed in the station ten lamps with the appliance on them, and had five lamps thrown in the circuit, but the circuit flashed so badly from the additional load of the five lamps upon the dynamo, that they cut them out and then the circuit went on, and they no longer tried to burn more than fifty lights on the circuit. As to the large number of renewals of the cylinders on the 16th, on that night and the date previous they had a very heavy storm of soft snow, about 18 inches of snow fell. The hood or storm protector of the lamp was of such a character that much of the snow flew in and as the water struck the appliance or globe, which is intensely hot, of course, it broke. The general characteristic of the light was somewhat different to the eye of the public from that of the ordinary arc lamp. The rays of the light were not as strong, but after the circuit was in good burning order it was found that the street was better lighted owing to the horizontal ray of the arc than by the ordinary arc which gave an intense light underneath but did not diffuse the light into the middle of the block. The burning of the lamp or carbons was such that they formed no crater as they do in the ordinary arc, but burn very slowly and with square ends. The claim of the maker was that they give a luminous body caused by the carbon monoxide gas; up to the present time it had worked very well in Buffalo.

In answer to a question by **Mr. De Camp**, **Mr. Huntley** stated that the machine would carry ten more open air arcs than enclosed arcs, that the consumption of the carbons was uniform and that the lamps required trimming every four days with a special carbon. The residents were well satisfied with the illumination; perhaps better than they were with the other circuit. Mr. Huntley could give no estimate of the saving in cost due to the method as all the apparatus, carbons, etc., had been furnished him free for this trial.

Mr. De Camp inquired as to the difference between the Howard device and that of the Baxter lamp of eight or ten years ago.

Mr. L. B. Marks, of New York, said that in looking over the patent situation on this question, he found, as Mr. De Camp had said, that arcs of this type were run years ago. The question which suggested itself was, Why were they not successful? There was first the blackening of the globe, due to the carbon, and the explosions due to the gases generated, owing to lack of means for its exit. Within a month, or two, they would present to the technical electrical world a solution of the gas question, the control of the gases, and a remarkable phenomenon, which had never been presented to the electrical world before, so far as his knowledge went, or as far as the opinion of some scientists with whom he had consulted was concerned, showing that by a slight change in the management of the gases and in the control of the arc they are enabled to prolong the life of the negative almost indefinitely. In fact, in the report of the test which came from their laboratory, the consumption of the negative was zero. One of the papers (The Electrical Engineer, Feb. 28) reported the life of the negative 200 hours per inch. His experience had been that with the change in conditions the life of the negative was 200 and 300 hours per inch. If we have an arrangement such that the enclosed gas has an opportunity to escape, but the ingress of the air is practically prevented, the pressure on the inside of the cylinder is less than the outside. If the pressure on the inside of the cylinder were greater than the pressure on the outside, we might expect an explosion; but under the conditions mentioned, he failed to see how it was possible, under any circumstances, in the normal operation of lamps on a commercial circuit to explode the cylinder. He put himself on record as stating that he had never known a cylinder, with a plug and controlling arrangement for the gases, as used in the Howard type, to explode; and he thought he might refer to Mr. Howard, who was the pioneer in the development of this new type of enclosed arc, that in his experience he had not known of a case of explosion. The results of tests according to his observations were slightly different from those of Mr. Huntley, regarding the shape of the tip. The crater was not exactly flat, but it extended over the entire surface of the carbon, being slightly hollow. The distribution of light was the important feature of this lamp, and he referred to some recent tests of Prof. G. D. Shepardson as bearing out his conclusions that with a small cylinder and a very thin coating they obtained a greater diffusion of the light than with a ground glass or milk glass globe. He also referred to the discussion of Professor Nichols, at the Chicago International Electrical Congress, who stated that the Howard arc gives a diffusion of light without loss of efficiency, which is not the case with opal or ground glass globes. Mr. Marks warned the members of this Association against remarks of certain carbon men which are intended for a specific purpose.

The meeting then adjourned until 2 P. M. After adjournment the delegates were photographed standing on the steps of Willard's Hall.

WEDNESDAY AFTERNOON SESSION.

The Convention re-assembled at 2:30 o'clock p. m.

Mr. De Camp resumed the discussion of Mr. Huntley's paper and was inclined to think that the system tested was not seductive to the station man. As to the question of saving in labor, he thought that even if the lamps did not require actual re-carboning, it would be necessary to inspect them as often as they were now trimmed.

Being called on by Prof. Anthony, Mr. L. E. Howard said that in regard to cleaning the light rod, the requirements changed with this new equipment. Instead of 8$\frac{1}{16}$ inches for part of a night's run, there is less than an inch of the rod that is used. No doubt in trimming the lamp it needed inspection after the first trimming; but having started properly, the adjustment of the lamp and its mechanism being fitted to the requirements, it needed no further attention until the run was completed. In regard to saving, it had been reported to him that the basis of income was to be the royalty. Such was not the case. It was proposed to furnish this equipment to the central station at a fixed price, guaranteeing a saving on the two items of carbon and trimming to be at least twenty per cent. on the present cost. In the matter of breakage, all new enterprises were obliged to go through a certain amount of experimental work. There was no additional cost for carbons to the central station; in fact it would cost them 20 per cent. less.

In answer to further questions Mr. Howard said that the lamp took about 62 volts and consumed the same energy in watts as the ordinary lamp.

Mr. Smith had used the Howard device and the diffusion was better. The amount of light furnished by the lamps was the same as with the old lamp. But at a distance they found that they got a better light. Having trimmed the light the first night it worked beautifully, but the next night it would not start. They tried to get rid of that by stiffening the carbon and while the lamps did not actually wedge, the alignment of the carbon was not good enough to admit of their running more than one night without trimming. The man did not have to trim, but he had to climb the poles to see that the carbons were right, and the whole attention to those lamps practically took as much time as would the trimming. But he judged the saving of one or two trimmers and the patroling would pay for the extra trouble. Mr. Smith also gave his experience with the Baxter lamp ten years ago, which frequently exploded its globe.

Mr. Howard, gave the reasons for the failure of the Baxter lamp; the vents were in the wrong place, and the construction of the cylinder itself, or jacket, was radically wrong. An ideal coating on the cylinder which they were using to-day increased the light. He had frequently known of cylinders to be in constant daily use for over thirty days without being touched in the way of cleaning. There was no residuum or final dust. There was a large percentage of safety and insurance against breakage outside of globes, and a material saving in the negative carbon of a double lamp; and also a percentage of saving in the wear and tear in the mechanism of the lamp.

Mr. Smith had proved by experiment that if a globe be etched on the inside instead of on the outside no light was lost. He also referred to a test of incandescent lamps etched on the inside which show 102 per cent. of the candle power of the unetched lamp.

Mr. C. R. Huntley was thoroughly satisfied that the diffusion of light was as good to any citizen that might look at it, as the open arc light, and he was not sure but that it was better. He was only speaking now of his experience in using the lamp out of doors, but the question came up, whether you can leave an arc light up four or five days subjected to the winds and weather, exposed to the small boy with the air-gun trying to shoot the globe off or to kill a sparrow.

Mr. Stetson said that in this twenty per cent. of saving ought to be included the dockage by the police for lamps out. If there could be a deduction of twenty per cent. on that, the Howard lamp was something they ought to have especially if the lamp was better for commercial purposes in stores.

The next subject taken up was:

WHAT IS THE MOST ECONOMICAL SIZE FOR ARC DYNAMOS?

Mr. C. R. Huntley stated that he had stations equipped with with various sizes of machines. If he were to place an order tomorrow he would try to get a 100-light machine for his stations. As to the danger, he did not think there was any additional; in fact nobody knew the difference, not even themselves when coupling two 60-light machines together. If he could get that power in one machine designed as efficiently and as free from burning out the armatures, he would be in favor of a larger unit. He was working an 80-light machine, and he would not like to be on record as advocating less than a 100-light unit, if he could get it.

Mr. Geo. A. Redman said he was in favor of large units but was prohibited by the city ordinance from going above 3,500.

Mr. J. I. Ayer had carefully noted and kept record of the line troubles on the different circuits, and the records on 80-light circuits showed no greater trouble than those on 60-light circuits. He operated for about two years and a half about thirteen 80-lighters. In a station where the number of lamps in operation would justify the use of the large units, he thought there was no question as to what should be used.

He had made some experiments with two 60-light circuits coupled together for sixty days, and did it in wet weather purposely. He found in a line with 130 lights, with two 60-light machines, that it was dangerous in the station. The current could be detected on the ground, by touching the insulator with a wet towel. In his experience one could not run any higher than four or five thousand volts on a circuit. It was a matter of insulation, something they hoped to overcome. An 80-light dynamo was perfectly practicable, however.

Mr. De Camp said he had long advocated large machines and had been running a 120-light Brush machine in his station for about three weeks, and so far as his experience had gone it was in every respect as feasible and as efficient as the 60-light machine.

The President announced as the next topic

HOW TO RATE ARC LAMPS.

After a preliminary discussion a resolution on the subject by Mr. Burleigh was referred to a committee of five consisting of Prof. Mendenhall, Prof. Anthony, Prof. Forbes, Mr. Weston and Mr. Hammer, with instructions to report at the following morning's session.

The President then, following the programme, inquired:

WHAT IS IT YOU WISH TO KNOW?

Mr. De Camp inquired whether the use of the battery in the Germantown plant had done anything more than to save the loss which the station showed while it was running on an unprofitable day circuit; or, in other words, knowing what the profits or results of the station were previously to the introduction of the day business, had the real substantial results increased since the introduction of the batteries in proportion to the increase of their business, or had the battery simply been a saver of what was lost?

Mr. Nicholls wanted to know if any advantage could be gained in his station which had a day load of 600 amperes and a night load of 700 or 800 amperes.

Mr. Wright, who is connected in a semi-official capacity with the Germantown Electric Co., said that the amount of their total loss by the entire incandescent business, which was composed almost half and half of direct current 220 volts and alternating current 1,100 distribution, was exactly the amount paid for the day circuit. The amount of saving had been stated as somewhere around $2,500; that saving was only figured on the rougher items, and from memory. The amount actually saved by the year's operation of the storage battery amounted to $700. The average output on each size was from 30 to 40 amperes from dawn to dusk. There was one point about this battery that ought to be mentioned, viz., that at Germantown the number of lamps wired was double the dynamo output. If they were going to do as well this year as last in the way of extension, they would have to look out and put in more direct current machinery. The depreciation was figured at 25 per cent. The new battery showed that it had earned about thirty-five per cent. on the amount of the investment during the year it was in operation. Of course, the conditions were experimentally favorable. The reason for this heavy depreciation lay in the fact that the first battery was overtaxed, and they proposed to avoid that in the future by using the newly installed battery of 2½ times the capacity.

Mr. Blackstone hoped that some of those batteries might be installed in the Brooklyn station. He also stated that the price of storage batteries was less in America to-day than in England or Germany.

Mr. Nicholls inquired how much of a battery would be necessary to take the peak of his load in winter nights 3 or 4 months of the year and take the whole night load during the remaining months.

Mr. Williams answered that he would have to know the precise conditions. As regards depreciation it was not fair to take 25 per cent. as the regular figure. According to Mr. Barstow 6 per cent. was a fair figure taken in Europe.

Mr. Nicholls said that while foreign competitors would guarantee 6 per cent. American manufacturers allowed 10 per cent., making a difference in the imported battery of four per cent. per annum. That should be taken into consideration.

The Convention then went into Executive Session.

THURSDAY, MARCH 1.—MORNING SESSION.

The meeting was called to order by Vice-President Francisco. The paper by A. B. Herrick on "The Development of Switchboards for Modern Central Stations," which was the first order of business, was read; being accompanied with stereopticon views.

In the discussion of Mr. Herrick's paper, Mr. Weston inquired why 20 degrees was taken as the standard of temperature? Mr. Herrick replied that it was an easy and ready method of determining whether the instruments were overheated; and the condition of emissivity and radiation are about the same for all the appliances.

Mr. Weston:—Some one has said that whatever is, is right.

Most of us that have lived very long have failed to appreciate the truthfulness of that statement. I think if the author of that statement had visited a few of our central stations and examined the switchboards and determined the amount of energy lost in the stations in this country he would never have uttered it. There are two ways of looking at that matter of loss; first, you may look upon it as the loss of what it costs to produce the energy that you lose; second, you may look upon it from the standpoint of what you could get for it if you sold it. To the business man the latter view is by far the more correct and more important, because, obviously if he gets 12 cents, which is about the average, I think, in this country, per kilowatt hour for the energy delivered to the consumer, that which he loses in the frittering away process in the conductors really represents a decrease in his revenues at that rate. This matter of central station switchboards is becoming more and more important every day, and the present board is unquestionably not the practice that will be followed in the near future. It will be totally changed and the appliances proposed by Mr. Herrick will in the comparatively near future be entirely abandoned; there is no question about this when station managers begin to realize how much they lose even on their switchboards.

I have made some calculations based on a selling price of 12 cents per kilowatt hour, and I have furthermore assumed that that kilowatt hour is maintained 24 hours a day, 365 days in a year. If you want to modify that you can do so to suit your particular condition. It is comparatively easy to ascertain just what you are losing; the general practice is to adopt about a million square mils per 1,000 amperes. In ten feet of such a conductor there would be a drop of one tenth of a volt with a current of 1,000 amperes. Now that looks rather small,—one-tenth of a volt; but expressed in dollars and cents at the end of the year it amounts to a great deal. On the plan proposed it amounts to $12.48 for every ten feet of that conductor. If you take a conductor of ten times that cross-section and ten times the strength of the current, viz., 10,000 amperes, it amounts to $1,124 per annum. Therefore, it is better to say that a fall of potential in a conductor ten feet long, of one circular inch, involves the loss of about $100 per year if run continuously. If it involves that loss in that conductor of course it involves the same loss in any other branch of the conductor,—any extension of it.

This question of loss at the switches is one that is something amazing. I had occasion a little while ago to examine two switches carrying 8,000 amperes. At the joints of the switch there was a drop of 240 millivolts; multiply that by the number of amperes, 8,000, and you will see that there was nearly two kilowatts in the joints. Continue that two kilowatts at 12 cents an hour during the year and it amounts to thousands of dollars. That was only the joints. There was an actual drop at the switch of 360 millivolts,—they want some severe reformation there that is sure. In the ammeter there was a drop of nearly two-tenths of a volt, with nearly 8,000 amperes, and the total loss in that one instrument and switch figures very closely to $5,000 a year. If there were about 30 or 40 instruments in the station you could see what it would amount to at the end of the year.

The ammeters themselves, every one of them, and the feeder ammeters take a large amount of energy; and everything possible should be done to reduce this loss to a minimum. I have selected one example which shall be nameless. This ammeter was a good deal better then the average, so far as efficiency, or economy more properly speaking, is concerned. This was a 600 ampere ammeter —a comparatively small one and in the conductor there was a loss of 21 watts. That looks rather small when the instrument was running at its full rated capacity; it amounts to a quarter of one cent per hour on the basis stated; that is six cents a day and amounts to a little over $22 in a year, but if you have ten of them it means $222. But that ammeter had joints in it and these joints were not well fitted, and there was a further loss in the joints which we will leave out of consideration at the present time. To use that ammeter it would require an average of ten feet of conductor to carry the current to and from it. In that conductor there would be a loss of 64.2 watts; the instrument and conductor together would represent $89 waste of energy on the basis stated. A very good form of ammeter of 600 ampere capacity required 18 watts to operate it; now that 18 watts ought to be got rid of, you can eliminate it if you use a shunt type of instrument properly designed. Do not use a specially constructed shunt but take the actual necessary drop of potential to utilize it to work the instrument, and the instrument which consumed 18 watts, practically consumes .0021 of a watt, and instead of costing $18 per year to run it, it costs you .22 of a cent. The result of this is that the switchboard should be brought as near to your dynamos as you can possibly get them; every inch of unnecessary conductor should be left out. Every joint should be left out that possibly can be and when joints are made they should have large surface contacts. When you make conductors do not make them in circular form, but make them flat. Give the conductor plenty of air so that there can be an abundance of the cooling action of the atmosphere. It is clear that the stations should be so arranged that your feeder circuits are as short as they can possibly be. Your switches must be made very differently from what they are now; polished brass looks pretty, but it is not what you want; do not sacrifice good qualities for appearance. Your conductor should be given plenty of space, they should not be laid flat on one side of the switch board, placed upon a slab, and closed at the bottom. Keep the temperature of the conductors down as low as you can; I do not know but what it would pay to put an oil bath around your conductors, and cool the oil by water.

MR. CHARLES F. SCOTT then read a paper on "Polyphase Transmission."[1]

THE PRESIDENT announced that discussion on the paper would be deferred until the afternoon session.

On motion of Mr. De Camp, the President appointed the following gentlemen a committee of five to make nominations for officers for the ensuing year: Messrs. De Camp, Weeks, Seely, Ayer and Carnes.

On motion the meeting adjourned until 2:30.

THURSDAY AFTERNOON SESSION.

PROF. ANTHONY, on behalf of the Committee on the Rating of Arc Lamps, presented the resolution drawn up by the Committee, which, after slight verbal changes, was adopted, as follows:

> Recognizing the difficulty, if not impossibility, of measuring with any degree of accuracy, the illuminating power of arc lamps, and the great necessity for a more precise definition and statement of the obligation of the producer of electricity for illuminating purposes to the consumer thereof, be it
>
> *Resolved*, That in the opinion of this convention, what is ordinarily known as a 2000 candle power arc lamp is one requiring on the average four hundred and fifty watts for its maintenance, the measurements being made at the lamp terminals where no sensible resistance is included in series with the arc. In case such resistance is used it must be excluded in the measurement of the voltage.
>
> (Signed)
>
> T. C. Mendenhall, *Chairman:* W. A. Anthony, George Forbes, Wm. J. Hammer, Edward Weston.

The Report of the Committee on the National Electric Light Association's Standard Rules for Electrical Construction and Operation was then taken up and after slight verbal changes was adopted.[2] On motion it was ordered that the rules be copyrighted.

The meeting then resolved itself into executive session.

EXECUTIVE SESSION.

MR. DECAMP Chairman of the Committee on Nominations, presented the nominatians for officers for the ensuing year as follows:

PRESIDENT, M. J. Francisco, Rutland, Vermont; 1ST VICE-PRES'T, C. H. Wilmerding, Chicago, Ill.; 2d VICE-PRES'T, Frederick Nicholls, Toronto, Canada. EXECUTIVE COMMITTEE: Chas. R. Huntley, Buffalo, N. Y.; A. J. Markel, Hazelton, Pa; W. W. Carnes, Memphis, Tenn.

Ballots were duly cast, and the gentlemen nominated were unanimously elected.

On motion of MR. JAS. I. AYER, the following resolutions were unanimously adopted.

> WHEREAS:—The success of the meetings of the National Electric Light Association depends in no small measure on the transportation facilities provided between the homes of the members and the various convention cities, and
>
> WHEREAS:—Mr. C. O. Baker, Jr., as Master of Transportation, has for many years, with great ability and generous devotion of his time and energies, presided over the arrangement and conduct of the special convention trains, some of which have carried nearly 200 members and friends, hundreds of miles, and
>
> WHEREAS:—Mr. Baker in the discharge of his duties has been not only careful to secure for each member thus traveling all possible comfort, but has endeavored to enhance in every way the pleasure and lessen the fatigue of the ladies, whose attendance at these meetings has become one of their brightest and most enjoyable features,
>
> *Resolved*, therefore, that for all his characteristic kindness, courtesy and self-sacrifice in this important and responsible work as Master of Transportation, the thanks, hearty and deep-felt, of the Association be and are hereby tendered to Mr. Baker, combined with the hope that the Association may long have the good fortune to enjoy such graceful and perfect service, and
>
> *Resolved*, that these expressions of esteem and appreciation be engrossed and presented to Mr. Baker, duly signed by the officers of the Association in its name.
>
> (Signed) JAMES I. AYER.
> T. C. MARTIN.
> FREDERIC NICHOLLS.
> *Committee.*

The thanks of the Association were tendered to the several street railway and telephone companies who had extended courtesies to the delegates during their stay in Washington, and to President Armstrong, for the able and pleasant manner in which he had discharged the duties of his office during the meeting of the Association. An invitation was presented by the Georgia Electric Light Co., of Atlanta, Ga., Mutual Light and Power Co., of Montgomery, Ala., and the Anniston Gas and Light Co., Anniston, Ala., for the Association to hold its next meeting in the City of Atlanta. On motion the invitations were referred to the Executive Committee.

FRIDAY, MARCH 2.—MORNING SESSION.

The meeting was called to order by PRESIDENT ARMSTRONG at 10:30.

---

[1] Owing to the delay in making the engravings accompanying Mr. Scott's paper, its publication together with the discussion thereon must be postponed until our next issue.

[2] See page 201.

The President called on Mr. L. B. Marks to open the discussion on the topic:

"ARC LIGHTS ON INCANDESCENT CIRCUITS."

Mr. L. B. Marks, before taking up the discussion of the subject announced said he desired to correct some misapprehensions which seemed to prevail on the report of Mr. Huntley's arc lamp tests at Buffalo. The impression seemed to be that the lamps tested required more energy for their efficient operation than do open air arcs. As a matter of fact the Howard bulbs do not consume more power, but on the contrary, when run at maximum efficiency can be operated at a less expenditure of energy. The machine referred to by Mr. Huntley and nominally called a sixty-five lighter was running on a circuit having considerably over ten miles of wire, in which the loss amounted to several hundred watts. Mr. Huntley stated in answer to a question at the session on Wednesday that he had been able to run fifty-five open air arcs efficiently on the sixty-five light machine whereas the same number of enclosed arcs appeared to overload the machine. He found, however, that fifty enclosed arcs could be very successfully operated and gave as good, if not better light, than the others. Thus the output of his machine was decreased by five lights. The whole question was simply one of voltage, for the enclosed arcs can be operated much more efficiently at a lower current than the open air arcs. A current of from 7 to 8 amperes answers the requirements much better than one of 9 or 10 amperes; hence though the most efficient potential difference of enclosed arc is in the neighborhood of 60 volts the actual consumption of energy when run under the proper conditions is no greater than in the open air full-arc. Moreover the machine can be so adjusted that the regulation at 8 amperes will be very efficient with the Howard system. It would be noted that whereas in open air arcs the consumption of carbon, and the consequent variation in resistance and potential difference of arc, are relatively great, such was not the case with the 100 hour enclosed arc; hence the regulation of the machine may be perfectly carried out, working at a higher point on the droop of the characteristic, reducing the current and increasing the E. M. F. Under some conditions it would be necessary to modify the machines in order to obtain the same number or a greater number of enclosed than of open air arcs on a circuit. The change was a simple and inexpensive one considering the advantages to be gained.

Coming to the subject announced, **Mr. Marks** pointed out that the record of inventions in electric arc lamps during the last few years had shown that the trend of development had been in the direction of their application to incandescent circuits. As far as the underlying principle of operation was concerned, it might be said that the various types of arc lamps for constant potential circuits were practically the same. The differences lay mainly in details. While the introduction on direct current incandescent circuits had been accomplished with a fair degree of success, the waste of a large percentage of energy in "dead" resistance was always involved; with a single arc across such a circuit, the loss of energy due to resistance in series might be from 50 to 60 per cent; with two arcs in series across the mains the loss might be reduced to about 25 per cent. On 110 or 120 volt circuits economical conditions required more than one arc lamp across the mains.

The performance of a pair of lamps connected in series on a constant potential circuit proved the conclusion which might be arrived at from a theoretical study of the conditions: First, that it is impossible to maintain a constant current through the arc branch; second, that it is necessary to insert a wasteful resistance of some magnitude in the arc branch to secure even fair results. In his admirable paper on "The Electric Arc and its Use in Lighting," read at the N. E. L. A. Convention, February, '91, Professor Elihu Thomson, alluding to the application of arc lights to constant potential circuits, had said: "A great deal of useless experimenting has been, and probably is yet, carried on with the vain endeavor of getting rid of the resistance or choking coil in this case, but the difficulty is inherent in the nature of the arc, the relation of resistance to current giving rise to instability of the current in the arc."

During the past few months Mr. C. Ransom and himself had been engaged in the development of what they believed to be an entirely new idea in arc lighting. He referred to what they have called the *high potential incandescent arc.* He had found that when the electric arc plays in an atmosphere of carbonic oxide gas, the usual relation of current, potential difference and maximum efficiency of an electrode of given diameter did not hold.

By confining the arc in a very small bulb, filled with carbonic oxide gas, they had been able to efficiently reduce the current and greatly increase the potential difference. For instance, with a pair of electrodes which in the open air arc light give a maximum efficiency at nine amperes and 50 volts, they had obtained excellent results at 4½ amperes and 100 volts, a condition impossible in open air arcs. They had no difficulty in running 100 to 120 volt arcs in this way, the current in each case being very small. The bulb used for this purpose is a modified Howard cylinder, containing a special device for controlling the inclosed gas. When operated under these conditions the arc is about half an inch long and very steady. The violet hue so common to open air long arcs is not marked, the quality of the light being especially valuable for in-door illumination. The life of a pair of 7-16 inch carbons in a 500 watt lamp is about 100 hours.

The application of this system to incandescent circuits and its advantages over the present method were apparent. It dispensed with the necessity of running two lamps in series, a single arc without appreciable dead resistance being sufficient to bridge the mains. It would be noted that the consumption of carbon is so slow that even if the points are fixed, the potential difference between the electrodes will not increase more than a few volts per hour. The comparatively rapid consumption of carbon in open air and the consequent changes in resistance and candle power of the arc, were in marked contrast to the above, and suggested an important advantage of the inclosed arc for constant potential circuits.

In the method just described the two elements whose product equals the consumption of energy in the circuit are susceptible of a wide range of variation, and may be adjusted to suit the conditions, just as the primary and secondary coils of a converter allow of great flexibility. With a potential of 115 volts between the carbon points and a current of four amperes, a single lamp consumes 480 watts on a 120 volt incandescent circuit, the amount of energy expended in the arc itself being 460 watts. The loss equals 20 watts per lamp, or 40 watts for two arcs, each directly across the mains. Comparing these figures with the data obtained from existing conditions, it would be noted that under the most favorable circumstances, the loss of energy for two open air arcs, each 460 watts, across 120 volt circuit, is 280 watts, as against 40 watts in the first case. Thus, there was a clear saving of about 20 per cent in energy accruing from the use of the high potential lamp. He would not consider the case of a single open air arc across the mains, such an arrangement being extremely wasteful of energy.

In the lamp constructed for their purpose, they have two regulating coils differentially wound on the same core, and in series relation to each other, one coil being in series with, the other in shunt around, the arc. By properly proportioning the coils they obtain a very sensitive feed. Summarizing, the advantages which may accrue from the use of the high potential lamp on incandescent circuits were as follows: (a) Saving in energy. (b) Saving in cost of trimming. (c) Saving in carbons. (d) Improvement in the quality of the light. (e) Subdivision of the light. (f) Cleanliness: no carbon dust or soot. (g) Perfect spark arrester.

Mr. W. S. Barstow, of Brooklyn, N. Y.:—As the history of low tension arc lighting began on the system of the Brooklyn Edison Co., I will simply give you as concisely as I can the advantages and disadvantages which have actually developed in commercial practice. The first disadvantages (in which we were immediately interested) were, 1. The requiring of a dead resistance in the circuit of the lamps which meant lost energy. 2. The requiring for commercial reasons of the installation of lamps in pairs.

It will not be denied probably by any one of us here that a low tension direct current system can easily manufacture current cheaper by employing large units operating in multiple than can a high tension system with its larger number of small machines. There is to day in this country a large company operating arcs on both high and low tension systems, and they have assured me, although they are wedded to neither system, that it costs them 25 per cent. less to manufacture current for their low tensions than for their high tension arcs. This is taken from actual results of the past year. With this condition before us we can easily see that we can well afford to waste 10 per cent. of energy on our low tension system outside of our station, especially when the customer pays for it. This last may make a few of you smile, but this same thing is done in high tension systems, the only difference being that in the latter the waste occurs in the station in the employing of small units, the price to the customer including this waste (which appears in the operating expenses upon which the price is based).

The question of desirability of installing lamps in pairs must be answered by the customer, and in Brooklyn the results will warrant a strong affirmative. In making a price for current for low tension arc lamps there must be taken into account the renewal of the lamp resistance, which will of course decrease in value as better methods of resistance are introduced. In order to get the same price for an arc current as for an incandescent current, which of course comes from the same generator, the price of current per 16 c. p. lamp hour was taken as a basis. It was then found that 9 cents per hour for a 1200 c. p. arc lamp current corresponded with 8 cents per hour for equivalent incandescent current, as the proportion of arc lamp renewals exceeded the incandescent. As the cost of labor in trimming an arc lamp is the same whether the lamp is burnt for one, two or six hours, it was found that in order to be fair in a meter rate a sliding scale should be used. Therefore, a scale commencing at 9 cents per lamp for the first hour and decreasing in proportion to the length of burning was adopted. It was further thought that if customers paid for current actually used without reference to the number of lamps installed and the company was to loan the lamps there would be no limit to the number of lamps asked for, while the customer would not bind himself to use all of them. This difficulty was easily settled by grading the discount price of current according to the lamp average hours per day, which was obtained by comparing the total current with the number of lamps installed. The first batch of arc lamps were installed in Brooklyn in the spring of 1890 and since then the progress has been very rapid, which can readily be seen in the fact that to-day we are operating about 2,700 lamps with orders ahead for some 400 more,—and now as to actual results.

It has been practically shown that our fears in respect to low tension arc lamps as regards the two disadvantages mentioned above were almost without actual foundation, and that we can to-day furnish lamps as cheap as our high tension competitors and still make as much profit as on our incandescent installation. The growth of the business in the face of competition I can only account for in the fact that the light is good, the control of pairs by individual switches a great advantage to the customer, as is also a meter basis for bills, while the low tension current admits of very ornamental fittings. While I am not here to boom low tension arc lamps, I can truthfully say my only regret in Brooklyn is that we have not more of them, as they have easily earned their share of our dividends.

In my hurried departure from Brooklyn, I was unable to collect what data I desired, but will submit to you a complete report on arc lamps for the year 1893, which will show more clearly the defects which we are now correcting—and almost all of these occur in the high tension system,—and as I have not accurate data on the latter I am unable to draw any comparisons but will leave that for you to do:

Number of Ward lamps in use	2,246	
Number of Bijou lamps in use	400	
Total number of complaints	3,911	
Defective carbons	2	per cent.
Retrims	7	"
Defective adjustment	12	"
Fuses and plugs blown—unknown cause	10	"
Loose connections caused by storms	6	"
Trouble with mechanism of lamp	12	"
Carbon holders broken and burnt out	1	"
Lamps grounded externally	8	"
Defective cleaning	16	"
Defective house wiring	2	"
Resistances burnt out and grounded	5	"
Defective installation	1	"
No trouble when men arrived	10	"
Special complaints	8	"
Total number of trimmers	17	
Average number of lamps per trimmer	144	
Maximum number of lamps per trimmer	170	
Maximum trims per trimmer	182	

Labor and material for repairing, repainting, rewinding resistances, and changing lamps, including testing of all new lamps,—75 cents per lamp per year.

Globe renewals exclusive of those paid for by customers—7 cents per lamp per year.

We are now working on a system of carbon renewals, which plan, though not a novel one, has not been in actual practice sufficiently long to warrant actual data. If finally successful, as there now seems no doubt of its being, it will effect a yearly saving of several hundred dollars, by enabling the company to reduce the waste of carbons caused by different rates of daily burning. Should any one desire further data in regard to low tension arc lamps on incandescent circuits, I trust they will not hesitate to call upon the Brooklyn Edison Co., who will always welcome members of the National Electric Light Association.

Mr. T. Spencer thought the great advantage in using arcs in this way was due to the fact that one class of machinery only is necessary which considerably cheapened the production of the current, and this was the principal reason why the alternating arc lamp had been introduced. The distribution of light from an alternating arc lamp could be regulated by a proper designing of the lamp. The most serious objection to the alternating lamp was the noise; but in spite of the noise he thought every central station man who had studied it had discovered that there was a wide field for it. Regarding the criticisms of foreigners on our arc lamps the principal trouble to-day was that Americans were using a carbon which no other nation would use.

Mr. Andrews of Philadelphia, said he had introduced a considerable number of arc lamps on incandescent circuits replacing arc lamps hitherto burning on the high tension circuits. He had also introduced incandescent arc lamps in places which had been hitherto illuminated with incandescent lamps, and in this way had increased the income of the station, and in a great many cases where customers who had been paying ten or fifteen dollars a month for incandescent lighting, and had constantly been grumbling about their bills, because they had not been satisfied with the quality of the light, by changing them over to incandescent arc lamps, and by increasing their bills to double, and giving them four to ten times as much light, they had paid the extra money and had been perfectly satisfied. He thought that arc lamps on the incandescent circuit would eventually supersede the high tension arc lamps, for many reasons, one of the principal reasons being that the customers wanted to be able to turn off and on their lights at pleasure, on dark days, for example, and not wait for the regular arc circuits to be turned on. He had had some experience with the Helios lamps and thought the alternating arc lamp, as a class, a great addition to the central station income. He charged by meter exclusively; he had been charging hitherto fifteen cents per thousand watt hours, and giving a varying discount, according to the size of the bills. His company trims the lamps. He agreed with Mr. Spencer's remarks regarding carbons and believed that as soon as the carbon manufacturers of this country were able to produce a carbon which would give the same effect as foreign carbons, it would give an additional impetus to the business, and it would be a great thing for central station managers. He would rather pay the same price or a little more to the home manufacturer of carbons than to go to Europe for them. (Applause.)

Mr. J. I. Ayer thought essential to emphasize this demand for a good carbon. In practice he knew that it was easier to get more money for a lamp with a first-class carbon than with ordinary carbon. It was a fact that we must get the highest grade of carbon.

Mr. Van Trump said that two years ago he decided to place arc lamps on the incandescent circuits at Wilmington; he had at that time a number of series arcs running. He had at this time 150 lamps on an incandescent circuit, and had increased the series arc business as well. He was getting a rate of 10 cents a lamp hour, about 21 cents per kilowatt hour, from his arc lamps, with a minimum charge of $2.50 per lamp per month.

Mr. Burleigh expressed surprise at Mr. Andrews' statement that he had materially increased the income of his station by using the alternating arc.

Mr. Stetson said he had installed two in a store and run them on a meter. The lamp was not satisfactory; he supposed that could be laid to the carbons; but the trouble came with the bills, and they were ordered out at the end of a trial. They were too expensive for his customers as against the regular series lamps.

Mr. Van Trump: The matter of arc lamps on incandescent circuits appears to me to solve several problems. We are now undertaking with that system work that I would hesitate to try with incandescent lamps, that is, the lighting of a large free library. We hang the lamps directly on the ceiling, burning them upside down, reversing the current, with a large reflector underneath. The light goes towards the ceiling; you cannot see the arc at all, and the room is thoroughly lighted from end to end.

The next topic taken up was

"METERS VS. FLAT RATES."

Mr. F. Nicholls: Most central stations who are using flat rates, are doing so not by choice but by force of circumstances. Companies that have commenced business on that basis have not been able to change without a loss of customers by reason of competition. In my experience nearly all companies supplying current on the flat rate principle are not furnishing lamp renewals free. In that case you will find that in nine cases out of ten the customer will purchase a low efficiency lamp and consequently the central station manager is furnishing from twenty-five to fifty per cent. more current than should be furnished if he had the right to say what kind of a lamp should be used. I know a company that I was called upon to advise with not long since, using low efficiency lamps, and carrying customers on the flat rate principle, that were furnishing 33⅓ per cent. more current that would have given the same unit of illumination if they controlled the renewals of the lamp. In the meter system, of course there is more or less conflict with customers as to the amount of current used. In this connection I wish to call attention to the fact that there is a bill pending before the Canadian Parliament for the appointment of government inspectors of meters and if there is any question between the company and the consumer as to the amount of current used the meter is to be examined and if it is found that the meter is in good working order the customer pays the cost of inspection, and if the meter is out of order the company pays it. This makes an easy method of determining these disputes which so often arise.

Mr. Scott thought it was only proper where a large quantity of water is used continuously or even occasionally that it should be measured, and the same rule would seem to apply to electricity. In dwellings it was good to have a meter but it was more satisfactory to have a flat rate for stores. We knew the hours required for lighting, the number of lamps necessary, and he had found that the merchant is usually satisfied with a fixed charge whereby he can gauge his running expenses. He had on incandescent circuit 365 contract lights and 1317 meter lights. The contract lights last year netted very much more than the meter lights.

Mr. Burleigh: I am operating two stations; one of them was formerly operated on the flat rate. We are changing that entirely to a meter rate, and in making the change have cut down our output almost one-half without materially decreasing our revenue. I regard that as a great argument in favor of meters. I believe it is the only plan, there is no other fair plan, whether it is a small customer or a large one.

Mr. Carnes: We have tried both ways, we have tried the flat way and now we are trying the meter, and recently made a rule that we will not put in a light except by a meter. I will give you one point to show how it worked with us. We had all we could do to carry what light we had to furnish; we have a capacity of 7,500 lights alternating carrying 15,000 lights wired. With the meter system we are now able to handle our costumers with perfect satisfaction.

Mr. Johns, of Cleveland: We have recently introduced the meter system in our city. We have one hotel from which we were deriving a revenue of $175 on the flat rate monthly, and from meter readings the bill was $1,100 at 16 cents a thousand watt hours; so that you can see what the meter meant in that one case.

Mr. Weeks, of Kansas City: I think no matter what the commodity is we have to sell, the only fair basis on which to sell it both for the producer and the purchaser, is a metric basis. I think the flat rate was one of the fundamental errors made by the electric light business at the outset. When our station was installed, it being the first of the kind in the world, there were no meters and for some time we hesitated and refused to install the incandescent light for that reason. We finally under pressure installed the incandescent system without service meters with the reservation that just as soon as a meter could be found we would have the right to install it. Upon that basis we undertook to give our customers a lamp for every gas jet, basing our charges upon their gas bills of the previous year. We finally got a meter to measure this service and found that we were getting pay for 32¼ per cent. of our output. We found after we adopted the metric system that we reduced our output 50 per cent. and increased our revenue.

The Convention here went into executive session. In executive session the report of the Secretary and Treasurer were read, which showed between 30 and 40 new members had been gained at this meeting.

CONVENTION NOTES.

The Souvenir of the Convention took the shape of a very pretty scarf pin in the shape of one of Gen. Washington's swords. It was of sterling silver, with the hilt finished in blue enamel. There was quite a rush for these, and no small amount of amusing intrigue and diplomacy was used to obtain them when the supply began to run short.

The Dance given at the hotel on Thursday night was a very bright and charming affair, thanks to the active supervision of Mr. C. A. Bragg, master of ceremonies. Dancing lasted for over three hours, and was very largely participated in. Few conventions have seen so many brides in attendance, and they were soon made acquainted with the fact that the Association boasts a number of talented waltzers.

The Lecture on "The Electric Lighting of the World's Fair and Some of Its Lessons," by Messrs. T. C. Martin and Luther Stieringer (consulting electrical engineer of the Fair) drew a crowded house in the Grand Army Hall on Wednesday evening. About one hundred views were shown, a large number of which were from photographs taken at night, of the fountains, search lights, cornice lighting, etc. Some of these photographs were quite remarkable. The lecturers have been collecting data and views for some time past. Special mention was made of the valuable help rendered by Mr. Oscar H. Baldwin, of the Westinghouse Electric Co., who had managed to catch some exceedingly good night pictures with his camera. It may be doubted whether so many night views of a scene have ever been presented before, but the use of non-halation plates has rendered work in this direction possible, that had not been previously contemplated.

Association Officers.—The new president of the Association, Mr. M. J. Francisco, is a member of several years' standing, the president of the Rutland, Vt., Electric Light Co., an old insurance man, and prominent for his active hostility to municipal electric plants, against which he has written and said a great deal. He will serve the Association zealously and loyally. His predecessor, Judge Armstrong, has large lighting and railway interests at Camden, N. J. Mr. Wilmerding, first vice-president, is now the confidential associate of Mr. Samuel Insull in the management of the Edison Electric Light Co., of Chicago, with special charge of the operating department. He has had a large experience in arc lighting and is now acquiring an analogous but probably a more pleasing one in incandescent work. Mr. Frederick Nicholls, second vice-president, is a man of most varied and responsible office, being a large manufacturer, the managing director of the Incandescent Light Co. of Toronto, the president of the Brantford, Can., Electric Street Railway Co.; vice-president of the Peterboro & Ashburnham Street Railway Co., and general manager of the London, Ont., lighting systems. Mr. Geo. F. Porter, the secretary, is about as efficient and energetic an officer as an Association ever had. The executive committee comprises men of prominence in the electric lighting industry, and active in the promotion of the common welfare.

EXHIBIT NOTES.

The Abendroth & Root Mfg. Co. which has been displaying so much successful energy of late in pushing its Root boiler among electric light and railway plants was represented by Mr. Maclaren, than whom no one is better acquainted with the field.

Jewell Belting Company, of Hartford, Conn., were represented by our old and true friends, C. E. Newton and C. L. Tolles. With their usual generosity on such occasions they were distributing to their numerous friends an exceptionally handsome leather card case, forming not only an ornamental, but a really useful souvenir of the Washington Convention. On this occasion they had no large belts on exhibition, but both Mr. Newton and Mr. Tolles had small samples of Jewell belting in their "inside pockets" which could be had on demand.

Doubleday, Mitchell & Co. were represented in force at the Convention, by the full strength of the firm, (except the company), both Mr. C. D. Doubleday and Mr. P. W. Mitchell being present. They were exhibiting samples of the well-known flexible conduit of the American Circular Loom Company of Boston, in sizes varying from ¼ inch to 1¼ inch inside diameter. They also showed a full line of the Doubleday-Mitchell quick break switch, in various styles, single, double and three pole, single and double throw, from 25 to 2,500 ampere capacity.

Davidson Ventilating Fan Company, of Boston, were represented by their general manager, Mr. Frank B. Parsons, of Boston. Mr. Parsons had with him several interesting models of the well-known Davidson Fan and other ventilating apparatus which he showed to many interested in this branch of electrical engineering. The Davidson Company have just recently become exclusive agents for the Meston fan motor in New England and are preparing for a large demand during the coming summer. This was Mr. Parsons' first electrical convention, but he appeared to be becoming rapidly initiated into the ways of electrical men on such occasions.

Page Belting Company, of Concord, N. H., had their New York representative, Mr. George F. Moore, on the ground looking after their interests, and giving away a large number of small booklets containing a vast amount of useful information on the subject of belting and transmission of power by belting. The book contains some good pictures of their World's Fair belts, and Mr. Moore also distributing a number of interesting souvenirs of the World's Fair which contains the now famous first representation of the St. Gaudens medal. Mr. Moore reports the order of a 48" link belt to be used for government work since his arrival in Washington, and an order of 1,000 feet for Yokohama, Japan, which orders have made him quite well pleased with himself.

The New Haven Insulated Wire Company, of New Haven, Conn., represented by Mr. C. I. Hague, showed a fan motor of new and original design. It carries a 24 inch fan, makes 720 revolutions a minute and at 110 volts consumes 1¼ amperes, exhausting about 7,500 cubic feet of air a minute. The name of the motor is the "Metropolitan," and it has a Gramme type of armature, with only one field coil, with projecting lugs encircling the armature. The commutator is on the side of the armature frame, and the motor is fitted with carbon rod brushes which are self feeding. They also showed a ¼ horse power slow speed motor, which only revolves at 600 turns per minute, and which has had a large sale, over 400 being now on order. Doubleday, Mitchell & Co. are their New York Agents.

The Standard Paint Company, of New York, manufacturers of the world-famed P. & B. paint and other specialties, were represented by Mr. Ralph L. Shainwald and Mr. Frank S. De Ronde, the latter gentleman, as usual, being loaded to the muzzle with the famous silver-lined brand of fragrant P. & B. cigars, which he presented with his inimitable grace to one and all on the slightest provocation. There was no real, live, red-headed P. & B. rooster here on this occasion, but Mr. De Ronde was quite as efficient in sounding the praises and virtues of P. & B. as a panacea for all electrical ills. Mr. De Ronde had with him also some very choice literature on the subject of P. & B., and is introducing a new tape, which will stick as long as there is any wire left for it to cling to, and which is put up for the market in such neat little boxes that one wishes to buy as soon as he sees it.

The Hart and Hegeman Manufacturing Company, of Hartford, Conn., were well represented by their popular treasurer Mr. A. H. Pease. They had an interesting exhibit of the favorite Hart snap switch in every variety, from the small 5 ampere size, up to their newest design of 50 ampere, double pole switch, which is a marvelously accurate, sure, and safe switch for its size. This switch has very heavy contact pieces and has ample ampere capacity, so that there is no opportunity for its getting out of order, sparking or getting overheated and burning up. It has a double break, quick and sure, and attracted a great deal of attention amongst the electrical contractors present. Another specialty which appeared to attract the electricians is their new flush switches, especially the lock and key switch, which cannot be operated except by possessors of keys, and is therefore incapable of being tampered with by meddlers. The flush switches have all handsome plates, finished to a high degree, with no screws in sight, and are elegant and substantial in design.

Dr. Chas. H. Bowen of Washington was there with his portable hanger for supporting cables in underground conduits.

Capt. Wm. Brophy was in attendance to represent insurance interests and to help find new definitions for "fire-proof."

The Stirling Boiler Co. was represented by Mr. Fred. A. Scheffler, not only a steam expert but one familiar with the modern branches of electric light and power from his responsible work in the factories of the Westinghouse, Brush and other companies.

The Electrical & Mechanical Engineering & Trading Co. of New York, was represented by its president, Mr. J. H. Vail, who contributed one of the most valuable and instructive papers, and had to answer a good many questions about metallic returns, rail bonds, &c.

The Carpenter Rheostats were represented by Messrs. Carpenter and Shain, while associated with them Mr. H. Ward Leonard had some very novel and ingenious forms of electric heating and soldering tools that seemed destined to begin a new era in that part of the industry.

Chas. A. Shieren & Co. were on hand with their celebrated perforated leather belting especially adapted for electric light and street railway plants. Mr. Chas. A. Schieren, Jr. and their hustling salesman, Mr. E. P. Atkinson, were in attendance as usual, also their Philadelphia representative Mr. G. H. Fisher.

The Johns Pratt Company, of Hartford, had their interests well looked after by Mr. E. B. Hatch, though their exhibit was in the charge of Mr. Henry G. Issertel of New York. No convention would be perfect without Mr. Hatch's cheerful presence, and he was at all times ready to explain the many virtues possessed by Vulcabeston and moulded mica.

Mr. Charles I. Hills, of Hartford, Conn., of "Novak" fame, was lying, a "sheer old hulk" stranded at the Ebbitt House, waiting like Micawber of old, for "something to turn up." He is an "opportunity" not to be lost on other more fortunate lamp manufacturers, who are free to sell, as "Charlie" has the reputation of being the banner lamp salesman of the country.

The National Carbon Co., of Cleveland, O., were represented by Mr. C. D. Smith, who paused for a few days in his travels to meet many of his numerous friends and talk "carbon" with them. The National Company will soon have a splendid new factory in Cleveland, which will be the finest manufactory of carbons in the country, with a very much larger capacity than their present accommodations.

The Electrical Engineering & Supply Co., of Syracuse, had an exhibit at the lower end of the red room, which was very noticeable in the way of a slate switchboard with ebonized wood frame and containing a variety of their knife switches, ammeters, voltmeters, patent concealed terminal and brackets. Their new quick break switch was also a novelty. The company was represented by their manager, Mr. H. J. Gorke, Mr. J. L. Hinds and Mr. J. D. McIntyre.

Messrs. Pass & Seymour, of Syracuse, presented a beautiful display of porcelain goods, including some new and difficult pieces which they pride themselves upon accomplishing. One was a porcelain screen, 2¼ inches in diameter, which contained 365 holes. They have a new insulating joint which is not affected by gas and has an inch insulating surface. Another special feature was their arc cut-out with porcelain case and cover. Mr. A. P. Seymour attended the exhibit each day.

The Eddy Electric Manufacturing Co., of Windsor, Conn., were represented by Mr. A. D. Newton, who favored Washington with a brief and flitting visit. Mr. Newton did not require to have any samples of their well-known type of motors and generators on exhibition, as they are so well known, but those interested in seeing Eddy machines at work in Washington, had only to step up to several of the Government buildings, where they can be seen in actual operation, doing yeoman service, year in, year out.

The Bryant Electric Manufacturing Company, of Bridgeport, Conn., were represented by Mr. W. C. Bryant, who had a very attractive exhibit set up, composed of a number of sample boards, on which were shown a full line of the well known Bryant sockets, switches, cut-outs, rosettes, etc. Some of the switches shown were of new design, and an entirely new design of the old favorite K. W. cut-out formed a special feature of the exhibit. This cut-out still maintains its well earned lead, and Mr. Bryant has recently made such changes in its design, as to enable him to put them on the market at a considerably lower price than heretofore. They showed also a new covered 500-volt cutout, which fills a long felt want, as it effectually prevents the molten metal of a blown fuse from scattering over surrounding objects to the danger of their ignition from the heat of the metal. Cleveland arc light cutouts of new and old design were also shown, the new design exhibiting many marked improvements over the old one in general, substantial features of construction and fireproof qualities.

The Electric Storage Battery Co. of Philadelphia displayed a variety of their battery plates and the merits of their celebrated chloride accumulator were set forth by Mr. J. R. Williams.

Mr. W. J. Newton was awarded the palm as the Beau Brummel of the convention. He represented the Newton Electric Co. of New York and showed samples of their cut-outs, switches, cord pendants, pole indicators, etc., of which they make a specialty.

The Columbia Rubber Works Co., of New York and Akron, O., had their trusty representative Mr. J. C. Pierrez on the ground looking after their interests and those of the Goodrich Hard Rubber Co. Mr. Pierrez had no samples in sight, but was full of information regarding all uses for hard rubber goods, not omitting the latest development in their business regarding the manufacture of the shells for telephone which they are now making and selling by the thousand.

The Vacuum Oil Co., of Rochester, N. Y., were represented by their special manager of the electrical department Mr. E. A. Record of Boston, who circulated around in his usual well lubricated manner, instilling a vast amount of useful information on the subject of oils into the ears of all consumers of this very necessary product. It matters not for what purpose one may want an oil, Mr. Record has a particular quality which will just suit and the high reputation enjoyed by his company in this field always bears him out in his statements.

The Okonite Co. was represented by Capt. W. L. Candee and Mr. G. D. Manson, with whom was associated Mr. G. W. McKinlock, of the Central Electric Co. of Chicago. As usual, the Company was rather slow to bother its friends with samples of wire and cable that had been seen before, many a time and oft, but preferred to dispense a graceful hospitality. On Wednesday evening these gentlemen took possession of a restaurant in the vicinity of the Pension Office, and there entertained a large company of friends with an oyster supper, to the pleasant accompaniment of a neat performance by the "two Boccaccios," Messrs. C. A. Bragg and Alec. Patterson.

The Carpenter Enamel Rheostat Co. exhibited for the first time an invention of H. Ward Leonard which promises to be of great importance for rheostats and electrically heated tools and utensils. On account of patents still pending the full details were not made public but the important results accomplished will be evident when it is stated that any device for the conversion of electricity into heat such as soldering irons, flat irons and certain rheostats can be constructed under the Leonard invention so that the device can, if desired, be operated continuously at a red heat or lower temperature without any destructive effect. Under the Leonard principle a No. 18 B. & S. German silver wire has been made to carry a current of 80 amperes instead of 4 amperes which would be its full current capacity if exposed to the air as usual. The Carpenter Co. is now ready to fill orders for the Leonard electric soldering iron which they are placing on the market at $5 each.

The Berlin Iron Bridge Co., of East Berlin, Conn., were represented by Mr. Burr K. Field, who secured a good position in the red room for an interesting model of their patent anti-condensation roof lining, which they have sold to so many electric light and power stations within the past year or two, and which is giving great satisfaction. The section showed the ordinary galvanized iron roof inside of which are two layers of waterproof paper, then two layers of asbestos paper, which are kept in place by a light wire netting. The iron purlins supporting the whole are 30 inches apart. No condensation can take place on the inside of such a roof, and after an experience of about two years the Berlin Iron Bridge Company recommend its adoption for all iron roofs with the utmost confidence. The waiting stand of one of the Washington street railways is equipped with this lining, as also the roof of the United States Electric Lighting Company's station in Washington.

The Hammond Cleat and Insulator Co., of Boston, were represented by Messrs. Frank W. Brigham and David J. Cartwright, and showed an extensive line of Hammond cleats, insulators, fuse rosettes, fuseless rosettes, waterproof sockets, wall receptacles, trolley guard insulators and porcelain arc light hanger-boards. Their new fuse rosette, illustrated with others of their most recent specialties in another column, is the only rosette made entirely in one piece with interchangeable fuse slide. It is absolutely waterproof and fireproof. The arc light hanger board made entirely of porcelain is new and possesses a number of important improvements over the old form of board. All the short circuit wires and connections are in plain sight on the outside, and there are no concealed parts or connections of any kind. They are also made adjustable so that one board will do for all three sizes of lamps in use, with plain lever or jack-knife switch. The trolley guard insulator is also new and is made in one piece, and can also be used as a strain insulator. All Hammond cleats can be put up with common nails, saving $3.00 to $5.00 per thousand on construction work.

The Washington Carbon Co. was represented by Mr. J. S. Crider, who was passing around sections of their new cored carbon, used for both arc and incandescent circuits; this is an article never before produced in this country.

Gen. E. S. Greeley, for once in a long while graced a convention with his smiling countenance and affable manner. As the Greeley company handle everything in the electrical supply line they did not deem it advisable to attempt to make an exhibit. Mr. Greeley, assisted by Mr. F. A. Magee, had an opportunity to shake the hand of many of their old friends and customers.

The Simplex Electrical Co., of Boston, were represented by Mr. J. H. Mason, who, while he had no exhibit, managed to find a number of friends interested in talking insulation, and extolled the particular virtues of the old standard "Simplex" wires. A convention without Simplex would seem unnatural.

The Jones Underfed Mechanical Stoker, was looked after by Messrs. F. G. Bolles & Co., of Washington, who had a number of other specialties in engines and mechanical engineering appliances, adaptable to electric light and power stations. The Jones stoker is receiving much attention from engineers at present, and bids fair to become extensively adopted in the near future.

Mr. Louis Stirn, President of the Universal Electric Pull Socket and Switch Co., New York, did not fail to attract the attention of every visitor to their novel pull sockets and switches as they passed up and down the stairs. Their sockets are adapted to all lamps and met with great favor. Mr. J. P. Freeman, the Electrical Inspector of Fire Underwriters for the District of Columbia, readily approved of both switch and socket and placed a handsome order for both with Mr. Stirn.

The Indiana Rubber & Insulated Wire Co., of Marion, Ind., had Mr. Frank W. Brigham of Boston in charge of their exhibit of wires and cables, which are all rubber covered. These samples embraced all styles, being solid, stranded or in cable form, for all capacities of light and power work. The insulation is rubber, and is double, the centre core being white, strongly braided and made for absolute safety. Large stocks of these wires are carried at 220 Devonshire street, Boston, and at 84 Frankfort street, New York, for quick shipment to all Eastern points.

The Ries Electrical Specialty Co., of Baltimore, were ably represented by Mr. Elias E. Ries, president and general manager of the company. They had on exhibition a full line of the well known Ries regulating sockets and switches which attracted considerable attention. The regulating switches are a recent production of the company and operate the same as the socket—that is, the same reaction coil within the switch regulates the degrees of light to any number of lamps from one to ten or more by a simple movement of the switch handle. The lamps are thus regulated to burn anywhere from their full brilliancy of 16 c. p. through various stages down to less than 1 c. p., after which the lamps are thrown out altogether, as in ordinary switches. These devices are intended for use instead of the regulating sockets in cases where the lamps themselves are out of reach or where a number of lamps are to be controlled simultaneously. The Ries Co., also exhibited photographs of their new Ries & Scott single and two phase alternating motors, a line of which they have in operation at their office at 7 Gay street, Baltimore.

The Buckeye Electric Co., of Cleveland, O., were represented by Mr. George R. Lean, who had with him a small portmanteau containing samples of the well known Buckeye incandescent lamps, plain, colored and frosted. Special attention was called to the 50 volt coil filament lamp, the only lamp of the kind on the market, and much interest was shown in their new non-infringing seal which is a marvelously clever device. On one of the stairs of the hotel, they showed one of their ordinary Buckeye 8½ watt lamps, and in the red room they showed their special 110 volt coil filament lamp, which is extremly small, and very well adapted for house and ship lighting. Considerable comment was made regarding the advantageous position which they occupy at present owing to the peculiar condition of incandescent lamp litigation.

Westinghouse, Church, Kerr & Co., of New York, were ably represented at the Convention by Mr. I. H. Davis, though Mr. William Lee Church put in an appearance on the last evening. Mr. Davis, besides paying considerable attention to their standard features of electrical engineering in their now well known type of "Kodak" stations, equipped with direct connected engines, mechanical draft and mechanical stokers, paid special attention to increasing the interest of central station men in their new combined ice-making and electrical plants, and succeeded in commanding a great deal of attention. Westinghouse, Church, Kerr & Co. are now recommending the adoption of ice-making as an auxiliary to electric lighting, as forty per cent. of the cost of manufacturing artificial ice is labor, and a large part of this expense is eliminated by the fact that in most central stations this labor has to be present in the day time, earning little money during the light day load. Should an ice plant be installed this labor could be turned to good account, and the product of the labor—ice—easily disposed of at a good profit.

The Electric Appliance Co., of Chicago, had Mr. F. W. Brigham at the Ebbitt House who, among a multitude of other interests, had still some time left to devote to their interests, though they made no special display.

The Chapman Valve Co., of Indian Orchard, Mass., were represented as usual by Mr. Edward L. Ross, who managed to put in some good words for Chapman valves in central stations. Mr. Ross did not require any samples of his goods with him but took pleasure in referring to the stations of the United States Electric Lighting Co., The Metropolitan Street Railway Co., and the Washington & Georgetown Railway Co., all of Washington and all of which are equipped with Chapman valves.

The Standard Underground Cable Co., of Pittsburgh, Pa., were represented by Mr. J. W. Marsh, vice-president of the company and our old friend Mr. George L. Wiley, of New York, without whom an electrical convention would indeed be incomplete. Mr. Wiley secured a pretty parlor on the first floor of the Ebbitt House, where he entertained hosts of friends, and showed a few samples of the well known Standard underground cables, particularly interesting being a few samples of the cables used in the $250,000 contract for underground feeders for the Philadelphia Traction Co., of Philadelphia, the largest contract for cables ever placed in this country.

Eureka Tempered Copper Co., of North East, Pa., were represented by Mr. John R. Coffman, who showed a full line of their specialties in tempered copper, consisting of commutator segments, for arc and incandescent dynamos and motors, commutators complete, dynamo brushes, arc and incandescent, and the Eureka gauze brush which is made up of a multitude of small wire, and has given great satisfaction, wearing perfectly smoothly, and incapable of unravelling owing to its peculiar construction. They also showed a very useful carbon brush holder for street car motors, and all kinds and sizes of sheet copper of different widths and gauges. Their new Eureka dry battery also formed an interesting feature of their exhibit.

The Helios Electric Co. of Philadelphia, were represented by Mr. Thomas Spencer, who talked about the virtues of the Helios alternating arc lamp and the Spencer economy coil. Mr. Spencer distributed much useful information regarding these specialties, drawing attention to two special features, namely, the reflecting enameled plate, by which all the light is utilized downwards, and the fact that these lamps burn with a much reduced arc, eliminating in a great measure the objectionable humming noise, common to most alternating arc lamps. The economy of the system of running these arc lamps in parallel simply, is accomplished by the Spencer economy coil which is used in connection with the lamp, which enables the Helios lamp to become a valuable and suitable lamp for inside lighting.

The Royal Arc Electric Co., of New York, were well represented by Messrs. L. E. Howard, L. B. Marks, A. H. Patterson and J. J. Gates. They exhibited two arc lamps in the main hall of the Ebbitt House, and one outside on the corner of F st. and 14th st., all equipped on the Howard system. These lamps elicited perhaps the greatest amount of attention of any exhibit at the Convention and Messrs. Howard, Marks and Gates were kept busy from early morning till late in the evening answering the multitude of questioners. The Howard device, which can be applied to any arc lamp, reduces the cost of trimming to a minimum, ordinary carbons lasting for about 60 hours, and special carbons over 200 hours. Merchants using the Howard system on their arc lamps are enabled to save a large percentage on insurance, the Board of Fire Underwriters in Hartford, where there are about 500 lamps operated on this system, having allowed the merchants in that city a reduction of 83⅓ per cent. The Royal Arc Co. are now in correspondence with electric light companies all over the Uuited States, relating to the adoption of their system.

The General Electric Company was represented by Messrs. S. Dana Greene, A. D. Page, Chas. B. Davis, T. Beran, Wilson S. Howell, A. B. Herrick, F. C. Todd, J. McGhie and one or two others, all more or less attached to the lighting and lamp departments of the General Electric business. Although its Supply Department made no special display of any of the novelties it has recently brought out, we noticed the new Thomson '93 arc lamp for incandescent circuits suspended in front of the Washington Agency, across the street from Headquarters. The simplicity of the lamp mechanism excited more than ordinary interest. The Supply Department showed also some of the new arc and railway wattmeters, constructed on lines somewhat similar to those of the well known recording wattmeters. Mr. McGhie, the company's press agent, reports that the General Electric Company is doing a really remarkable business, considering the hard times. Its Schenectady Works are swamped so far as its railway motor and generator departments, and cut-out, switch, regulator and other departments are concerned. The meter and arc lamp departments at Lynn, are both working full blast to fill the orders continually pouring in, and the Lamp Works at Harrison are, to day, many thousand lamps behind on their orders, despite their extensive facilities.

The Brush Electric Co., great progenitor of the companies that originally formed the Association, was most admirably represented by Mr. S. M. Hamill, jr. and Mr. Prentiss.

Messrs. P. J. Murphy & Co. of New York had an elaborate display of slate finished in marble, oak wood, polished black, Mexican Onyx and many other styles used for switchboards, bases and all manner of purposes where slate is required. They also had a new combination brass bolt and cap for mounting switchboards on either wood or iron frames. Mr. P. J. Murphy was present and, we hear, pocketed some fine orders.

The Baltimore & Ohio R. R. Co. deserve a word of praise as one of the most obliging and considerate railway companies that the association has ever had to deal with. It not only ran its fine special train with nearly 200 passengers over the road at a record-breaking rate of speed, but showed itself in a variety of other ways most anxious to treat the members handsomely. To deny it this brief word of praise would be sheer injustice.

The New York and Ohio Co. were represented by their secretary, Mr. W. D. Packard, and their Philadelphia agent, Mr. B. B. Downs. A display of incandescent lamps was shown in various sizes ranging from the 5 candle power baby to their mogul of 500 candle power, one of which was placed in the centre of the red room to give light for the exhibitors. The above display was also combined with that of the Packard Electric Co., who manufacture the Packard transformers.

The Pettingell-Andrews Co., of Boston, were well represented by Mr. C. B. Price, who without any samples, contented himself with circulating amongst the electrical men, and looking up the prospects of his staff in the spring for their well known specialties, paying special attention to the prospects of railway business, a branch which they have recently taken up on a larger scale. Mr. Price was well pleased with his visit and reported increasing prospects and much promise for good business in the near future.

The Mather Electric Co., of Manchester, Conn., were represented by their new vice-president Mr. T. C. Perkins, who did not bring any samples of his goods with him, but contented himself with showing his friends numerous plants in the city of Washington installed by his company, there being in fact a plant of 600 lights in the Ebbitt House, of the Mather system installed about two months ago. Mr. Perkins claims that there are more isolated Mather plants in the city of Washington than those of all the other electric companies combined. Mr. Perkins was well pleased with his trip to the Capital, and claims to have practically closed several more important contracts for large buildings in the city.

The Holtzer Cabot Electric Co., of Boston, were represented by Mr. H. E. Hall, and had their exhibit installed in the store of our well known friends, Royce & Marean, of Washington. They showed their new alternating fan motor with a 12 inch fan, of great power and capable of running at two speeds, 1500 and 2200 revolutions per minute, by means of a commutating switch at the base. This machine, unlike most other alternating fan motors, starts at once at full speed, and is not dependent upon any synchronous movement with the generator. They also showed a full line of direct current fan motors of all sizes from 110 to 500 volts. Their new ceiling fan of entirely new design, attracted a great deal of attention, as it is the only fan of this kind in the country equipped with alternating motors. The peculiar feature is that the globe supporting the fans is revolved by means of a small friction pulley on the extension of the armature shaft. The alternating type of this fan is fitted with ball bearings, runs very noiselessly, and is very economical, consuming only 70 watts.

The Phillips Insulated Wire Co., of New York, whose factory is at Pawtucket, R. I., were represented at the Convention by Messrs. H. C. Adams and A. A. Knudson. Their exhibit was composed almost exclusively of their new "Ideal" wire, and a practical test under water was shown which attracted a great deal of attention from those interested in insulation tests of wire. Two coils of wire, each about 25 feet long were shown, submerged in a basin of water, through which passed current for an incandescent lamp in the immediate vicinity. These coils have been submerged for over two months, having been put into water December 26th, 1893, at 5. P. M., and they were brought to Washington submerged in a waterproof bag. No apparent escape had yet shown itself, and the incandescent lamp burned perfectly, steadily and brightly. The insulation consists of raw cotton applied to the wire by a patented process. The method of applying the raw cotton is such that it produces an insulation apparently quite homogeneous, with very high insulating properties. It is well adapted for outside line construction, where good insulation is wanted, as it will not deteriorate like so many rubber insulations, though it is not recommended for continual submersion. It is attracting much attention amongst the trade, and is already being largely adopted especially by the telephone companies for their aerial lines where formerly rubber covered wires were used.

The Cutter Electric & Manufacturing Company, of Philadelphia, were represented by Messrs. H. B. Cutter and C. E. Bibber, who showed some very interesting and novel features in switches and lock switches. The first of these was the "Automatic," the money saver, a switch so arranged in a door lock, that when the guest of the hotel leaves his room, the locking of the door turns out the incandescent lights on the inside. Then they showed a switch for use in dark closets, safes, &c., where the closing of the door shuts off the inside light. A full line of C. S. flush commutation switches were shown, by which a lamp or circuit of lamps can be operated from three or more stations. Probably the most interesting feature of the exhibit was the C-S automatic cutout for electric cars, which effectually protects the armature, and at the same time prevents any sparking when the circuit is broken, and has none of the bad features possessed by so many other automatic cutouts for this purpose.

Mr. Henry G. Issertel, E. E., was formerly associated with the A. B. C. Company, of New York, but now occupies the unique position of electrical broker, in which capacity Mr. Issertel keeps abreast of the times in the most recent novelties, and keeps in touch with the central stations at all times, carrying the best articles at the lowest prices. On this occasion Mr. Issertel showed a very handsome board containing some beautiful samples of Iona specialties manufactured by the Iona Manufacturing Company of Boston. They make a specialty of decorative China switches for the interior of houses and the designs in general are extremely handsome. There were also shown numerous samples of the well known specialties of the H. W. Johns Company of New York, in vulcabeston and moulded mica, for electric light and railway purposes. Mr. Issertel also represents the Bernstein incandescent lamp, although there was no display made, Mr. H. B. Cram not being able to be present this year. Mr. Issertel distributed to a select few of his more intimate friends a complete box of choice "chips," with whose use some of the delegates to conventions are not totally unfamiliar.

The Interior Conduit and Insulation Co., of New York, represented by Mr. Romaine Mace, exhibited two very handsome boards fitted up with samples of interior conduit in all styles, plain, brass covered, and iron armored. The last style of conduit being their latest production, and the most perfected, attracted the greatest attention, and samples of these goods were shown from ⅜ inch inside diameter to tubes as large as 3 inches inside diameter. The conduit of their usual manufacture is inserted in ordinary wrought iron water pipe tapped at both ends, the joints being made by iron couplings, a fibre washer being inserted between the two lengths of conduit, thereby making a perfectly watertight joint. This form of conduit has specially recommended itself to architects, from its substantial nature, and from the ease with which it can be installed in buildings without the necessity of waiting for masons and plasterers, the installation of the conduit being perfectly feasible at the same time as the construction of the iron work of the building. They also showed a new conduit fitted with interchangeable safety fuses, mounted on detachable safety catches. Mr. Mace also distributed catalogues of the Interior Conduit Company's motors and dynamos, which have recently had a large sale for marine purposes. He gave away large numbers of the latest number of the admirable *Architects' Electrical Bulletin* published by the Interior company, and which was a particularly handsome and interesting issue.

The W. S. Hill Electric Co., of Boston, were well represented by Messrs. W. S. Hill and George M. Poor, who exhibited some of the handsomest and most substantial switches at the convention. The exhibit consisted of a solid polished oak table four feet square, supporting two frames set diagonally and pitched like a roof meeting at the top, on which were mounted two solid slabs of Tennessee marble carrying the switches. The exhibit was complete in every detail, the whole being shipped from Boston in parts, and set up in Washington in 85 minutes. On one side was mounted a 1,000 ampere, three pole, double throw switch, one of a lot of 185 recently made and shipped to the Philadelphia Traction Company of Philadelphia. This switch occupied the whole of one side and is of the most solid construction and handsome appearance, the brass work being finished in the highest degree, as are all the switches made by this company. On the other slab of slate, a 1,000 ampere single pole double throw switch occupied the position of honor in the centre, flanked on either side by a 100 ampere, double pole, single throw switch, one having fuse connections on the face of the slab, and the other having similar connections on the back of the slab, showing the two methods of accomplishing the same object. Above the switches were shown on one side two new closet switches, and on the other side two Hill plug locking cutouts. On the left hand upper corner was shown a switchboard rheostat and on the other corner was shown the new Doane lightning arrester, illustrated in another column of this number. Lying loose on the table was shown a section of the regular Hill arc switchboard, showing the breaking and transfer plugs. The whole exhibit was extremely handsome and appropriate and reflected great credit on the Hill Company.

Mr. C. H. McIntire was on hand with samples of the well known McIntire joints, whose use is now so universal in the various branches of the industry.

The Belknap Motor Co., of Portland, Me., were represented by Mr. Brown, who looked well after the interests of his company from down East, though he had no exhibit.

The Consolidated Electric Storage Co. of New York were on hand with a variety of storage battery plates made under the Brush and other patents. The company were ably represented by Mr. Wm. Bracken and Dr. P. G. Salom.

The Falls Rivet & Machine Co., of Cuyahoga Falls, N. Y., were represented by Mr. E. L. Babcock, who had his son with him. The many virtues possessed by the Falls Rivet clutches, were well stated by Mr. Babcock who lost no opportunity of talking with his many friends amongst central station men.

Mr. Fred. A. Duggan, proprietor of the Imperial Porcelain Works of Trenton, N. J., found business too pressing to admit of his making an exhibit at the convention. He arrived, however, on the third day with a few samples of their porcelain specialties and distributed some of their new illustrated price lists.

Mr. P. H. Alexander, of Baltimore, who has now taken up the profession of Consulting Electrical Engineer, circulated among his numerous friends in the corridors of the Ebbitt House, and renewed many friendships. Mr. Alexander was looking well, and appeared to be as well posted on current topics as ever, and talked with his usual suavity of manner and impressive effect.

Mr. W. J. Morrison was very much in evidence as usual, as representative of the Fort Wayne Electric Co., with one or two purchasers of plants, to whom he could refer inquirers as to the excellence of the apparatus. Mr. Morrison had a cheery word for the disconsolate, a bottle for the sick, and a card layout for the festive, as well as philosophical reflections for the high minded and serious remarks for the elder and the deacon. He was as ever, a convention in himself of all the amiabilities.

Mr. Frank Ridlon, of Boston, was rather unfortunate in his visit to Washington, as he was attacked with a serious sickness on the very evening of his arrival, and had to be removed to the house of some friends. He managed to recover sufficiently, however, to be able to show himself around the corridors of the hotel for one day before the Convention adjourned. Mr. Ridlon has come to be looked upon as a natural adjunct to an electrical convention, and his portly form and smiling countenance were much missed.

The Weston Electrical Instrument Co., of Newark, presented one of the most prominent exhibits in the red parlor where all their latest novelties in electrical instruments were displayed and attracted considerable attention. One of their most novel instruments shown was their new Van Vleck station ammeter and voltmeter of the edgewise pattern for central station work especially convenient where space is limited. The company were represented by Mr. Edward Weston, Prof. R. O. Heinrich and their New York selling agent Mr. Chas. D. Shain.

The Whittingham Electric Heater was shown by Messrs. E. B. Gawthrop, F. F. Della Torre, C. C. Hughes, 915 Equitable Building, Baltimore. The apparatus is very ingenious and attracted a large amount of attention. It consisted, essentially, of iron tubes encasing glass tubes with sand packing between, and a coil of wire running through the glass in suchwise that the spirals touched the glass. The ends were stoppered with lava tips. The wire was No. 22 iron, and the glass tubes were about ¼ inch in diameter. The heater and oven was built up of eight 1-inch tubes 18 inches long, while the same idea was also carried out in another form for kettle boilers, griddles, &c. The device heated up with remarkable rapidity, and was said to be very durable and economical.

The F. P. Little Electric Construction and Supply Company was represented by Mr. F. P. Little himself, the treasurer, Mr. F. W. Williams, and by Mr. J. F. Kester, the inventor of the famous "Kester" arc lamp. The exhibit of this company was in the red parlor and consisted of arc lamps for direct incandescent circuits between 50 and 120 volts, arc lamps for alternating circuits from 50 to 100 volts, besides lamps for constant current circuits of from 6 to 10 amperes. The company also showed a line of single and double throw knife switches for station use. It had also on exhibition some Kester commutator compound which is fast becoming popular for dynamo and motor commutators. The arc lamp which was burning so beautifully in the red parlor during the Convention, was a "Kester" constant potential lamp, running from a 110 volt circuit. This lamp will feed within 3 volts. From time to time Mr. Kester placed globes of different descriptions on his lamp and illustrated how expeditiously this change could be made. Mr. Little naturally feels good over the fact that by the third day of the Convention he had taken actual orders for more than 70 of these "Kester" arc lamps, to be delivered at once. After the Convention Mr. Little left for Asheville, N. C., where he intends to take a much needed vacation.

The Chas. Munson Belting Co. were represented by their president, Mr. A. Groetzinger and their Chicago representative Col. J. H. Shay.

Mr. Felix Haac, of the American Silk Mfg. Co., Philadelphia, presented a few samples of their patent silk machine wipers. They are said to be economical, safe and practical.

Messrs. Diehl & Co., of New York, were represented through their Washington agents, Messrs. Jordan & McLeod. They had on exhibition one of their most recent inventions—a combination electric fan and electrolier, containing six incandescent lamps so arranged that one or all can be used, the lights and fans being independent of each other.

Mr. John McLeer, the electrician of the Camden & Amboy division of the Pennsylvania R. R., was one of the most intelligent and quietly observant visitors to the convention. His presence may well be regarded as a sign of the manner in which electricity now touches the largest and most varied interests and is watched by their progressive officials.

The General Incandescent Arc Light Co. had several of its handsome lamps in service in the hotel. Its two-light chandelier on the second floor was a beauty and attracted considerable attention. Both alternating and constant current lamps of their most attractive patterns were scattered about the building. Mr. S. A. Douglass assisted by Mr. E. Lavens and Mr. G. Kirkegaard was kept busy showing their lamps to visitors.

Royce & Marean, represent to many electrical people the central, permanent point of interest in Washington, and their store adjoining the Convention Hall was a great rendezvous during the week. Mr. Royce was more attentive and obliging than ever, and was asked in return to take up half a dozen new agencies. Should he do so, it is his intention to issue shortly another edition de luxe of his beautiful and copious catalogue.

The Columbia Incandescent Lamp Co., of St. Louis, was represented by President J. H. Rhotehamel, who thus had the pleasure of meeting a good many customers and of repeating to several inquirers his statement that he intended to carry out to the end his hitherto successful legal fight, and that all purchasers would be protected and guaranteed by his company. Mr. Rhotehamel indicated some interesting new ideas and lines of development.

The Crocker-Wheeler Electric Co. were well represented by Dr. S. S. Wheeler, Mr. H. L. Lufkin and a beautiful new armature. The store of Royce & Marean was frequently visited by those who wished to examine the armature, which weighed 540 pounds, and was built up entirely without wire and without solder, and finished in the highest possible style of the motor-making art. The company has lately been invited into a number of new fields of motor design and application and is again busy with wonted orders from central stations.

Mr. W. Forman Collins, the business manager of the *Western Electrician*, deserved a better fate than attended him. It was his first convention as one of the proprietors of that journal, and he had made the trip from Chicago in spite of sickness. Arrived in Washington he had to succumb to pain and fatigue, and although he struggled bravely into his clothes once or twice, the larger part of the week was spent in bed. He received a great many callers and sympathizers in his room, and heard many regrets at his enforced absence from the convention hall.

The Norwich Insulated Wire Co. was represented by Mr. Geo. J. Jackson, who showed with pardonable pride the latest product of the Company's works. This consists of a three conductor cable intended for an alternating 3-wire circuit and weighing 15 lbs. to the foot complete, while the copper alone weighs 9 lbs. per foot. The cable is built up of a central stranded core insulated with the company's paper insulation and having laid about its circumference the two outside conductors, the combined conductors having an area of 3,000,000 circular mils. The cable is enclosed in wrought iron or lead pipe. The exhibit also included a display of 105 different samples of wires and cable made by the company, from No. 22 to 3,000,000 circular mils area.

The Love Conduit Railway System which has been fully and frequently described in these pages was inspected by a great many delegates, under the guidance of the electrical engineer of the road upon which it is used, Mr. M. D. Law, one of the oldest members of the association. One of the editors of the **Engineer** visited it immediately after the extremely heavy snowstorm of Sunday and Monday, and found it in admirable operation, although at one end water was pouring into it from melting snow banks just as though it were a tank. The general impression among the delegates was that it showed conduit roads to be entirely and commercially operative. As one of the best known engineers in the field put it: "This road is just as far along as was Frank Sprague's pioneer road at Richmond, and it will be just as much a historical starting point." Mr. Law deserves much praise for the work he has done in developing and perfecting Col. Love's ideas.

Mr. C. S. Van Nuis traveled around with a miniature "Ajax" switch in his pocket.

The New York Insulated Wire Co., were represented by Mr. Frank Harrington.

The LaRoche Electrical Works were represented by Mr. Frank R. Ford. It had been the intention of Mr. Fred. A. LaRoche to attend but very important business called him away in another direction.

The Donaldson-McRae Storage Battery was shown in one of the parlors, and exemplified a practical type now in large use in Washington, Baltimore, etc. They were represented by Mr. W. W. Donaldson and Mr. Smith.

The Westinghouse Electric & Mfg. Co. were represented by Messrs. Baldwin, Stilwell, Townley, Bragg, Scott and Heinrichs. A neat pamphlet was distributed, on the merits of the Westinghouse series direct current arc lighting system.

Mr. J. A. Pentz of Philadelphia showed a most ingenious and novel form of storage battery plate of the Planté type, produced in a manner new to the art and permitting a very rapid formation of the cell, as well as of enormous capacity. Details may be looked for at an early date.

The Electric Construction and Supply Co., represented by Mr. R. B. Corey, had been preparing a fine exhibit of its arc lamps on incandescent circuits in Washington for some time past, and the result was that delegates found hundreds of these lamps in choice positions all over the city.

The American Electric Mfg. Co., of St. Louis had no exhibit at the convention but were ably represented by Mr. Louis Nahm, who distributed a very choice little souvenir in the shape of an American lamp resembling a balloon, with rigging and basket attached. It is at once pretty and ingenious.

The Sunbeam Lamp Co., was represented by Mr. F. S. Terry, to whom an electric light convention is but a gathering of old friends and acquaintances not a few of whom hastened to extend him their warm and hearty wishes for a new career of larger prosperity, under the changed conditions. Few men in the field present so strong a combination as does Mr. Terry, of youth, energy and experience, all of which will again find their opportunity in better times.

Queen & Co., Incorporated, of Philadelphia, attracted great attention with their display of "Acme" hot-wire voltmeters, portable, switchboard and recording types, as also "Acme" portable testing sets, cable testing apparatus, etc. The "Acme" voltmeters are extremely compact and well made. They are accurate alike for alternating and direct circuits and are dead beat, without the use of a mechanical brake—this latter feature being possessed by no other standard alternating current voltmeters. A neatly prepared price list was distributed, which gave full particulars as to ranges, styles of mounting and prices. Instruments are supplied with single or double scales and with multipliers of any desired capacity up to 5,000 volts. Next to refined accuracy the most important fact about the "Acme" voltmeters is the remarkably low prices at which they are offered, thus making it possible for every plant, however small, to have strictly reliable testing instruments. The "Acme" Portable Testing Set, samples of which were displayed, is the multum in parvo of a resistance measuring instrument, as it contains Wheatstone bridge, rheostat. D'Arsonval galvanometer and silver chloride battery—all in a highly finished mahogany case 8¼" x 5¾" x 5". It has a capacity of several megohms and in addition to insulation tests is well suited to determining the resistance of dynamos, motors, lamp filaments and for general laboratory measurements. The Queen exhibit was in charge of Mr. J. G. Biddle, manager of Electrical Department, and Mr. E. G. Willyoung, electrical expert.

LETTERS TO THE EDITOR.

THE GIBBS-BRACKEN STORAGE BATTERY CONTROVERSY.

In stating to the public our position in respect to the unwarranted statements and claims made by the Consolidated Electric Storage Company as to our infringement of the Brush patents, it was not my intention to enter into a newspaper controversy with Mr. Bracken, but in view of his attempted reply, I desire to state further:

First. He states:

> "We disclaim Mr. Gibbs' charge of the circulation of any objectionable matter in relation to his battery, except that in one or two instances we have sent to purchasers the usual notice of infringement."

The following is a copy of letter written to the Provident Life & Trust Company of Philadelphia (one of our most prominent financial institutions) accompanying the "usual notice of infringement." Please note the date: December 8, 1892:

> "Office of Consolidated Electric Storage Company,
> 926 Drexel Building, Philadelphia,
> December 3, 1892.
>
> Samuel R. Shipley, Esq., President,
> The Provident Life & Trust Company, Phila., Pa.
>
> Dear Sir:—
>
> In passing by the Provident Building yesterday I noticed that you were receiving a number of electrical accumulators or storage batteries, presumably for the purpose of electric lighting. These batteries we understand were made at Gloucester, N. J., and are a most flagrant infringement of the Brush patents controlled by this company.
>
> In view of the repeated warnings you have had from this company, in shape of circular letters advising you of the scope and validity of our patents, it is difficult for us to understand why a reputable concern will deliberately violate the adjudicated rights of this company.
>
> We therefore warn you again to desist from installing and using these batteries or we shall be compelled to enter suit against you for infringing our patents. We enclose circulars relating to the same, in case they may not have been brought to your personal attention and if you will consult your attorney about the matter, he will certainly advise you to respect our rights. Yours truly,
>
> The Consolidated Electric Storage Company,
> Pedro G. Salom, Secretary."

The installation referred to was put in at that time and has been in continuous and successful operation up to the present time, and no suit was instituted.

This is the character of communications and statements that they have continued to make. We leave it to the public to judge of whether they are objectionable in view of the fact that no court has determined the Chloride Battery to be an infringement of the Brush or any other patents.

In the second place, Mr. Bracken states that the Société Anonyme pour le Travail Electrique des Métaux, of Paris, manufacturers of the Chloride Battery in France, was sued last year by the company owning the French Faure patent, and that Baron Rothschild, who is largely interested in the Chloride Battery Company, purchased peace at the expense, as he is informed, of several hundred thousand dollars.

This I state to be unqualifiedly false, and it seems remarkable that Mr. Bracken would make a statement the correctness of which can be determined by the records, without ascertaining as to its truth or falsity.

The facts are that the Société Francaise of Paris, controlling the Faure-Sellon-Volckmar patents (which are patents covering the ordinary pasted or red-lead plate batteries) brought suit against one Pollak, who manufactured a battery having a lead support or base with finely divided elongations in which the active material was pasted and pressed, the variation from the Faure patents being only in the particular method by which the active material was mechanically applied. This case was tried. The District Court, on the testimony of the experts, decided in favor of Pollak. This was appealed and the higher court reversed the decisions. This placed the Société Francaise in a position where their patents in France practically controlled all the pasted or red lead accumulators.

As there were a large number of manufacturers in France, as there are in this country, making these inferior types of battery, through the defects and failure of which the accumulator business has been so greatly discredited and demoralized, the company owning the Chloride battery, controlled by the Rothschilds, concluded that the purchase of these patents for a nominal consideration would be the best means during their unexpired term of about two years, of removing from the accumulator field these inferior types of battery, which, notwithstanding fourteen years of failure, still continued to claim merit, and made it all the more difficult to convince purchasers that a new principle had been discovered by which a reliable and commercially successful accumulator could be produced. It was for that purpose, and that purpose only, they purchased these patents. No suit was ever instituted under the Faure patents against the Society controlling the Chloride Accumulator in France. I therefore leave it for the public to judge whether any further statements that Mr. Bracken may make in defense of his position are worthy of consideration.

In view of the foregoing, I need hardly add that it is not incumbent upon me to defend Professors Chandler and Barker against any statements of Mr. Bracken.

W. W. Gibbs, Prest.,
Electric Storage Battery Co.,
Drexel Building, Philadelphia.

Philadelphia, Pa., March 2, 1894.

Mr. W. W. Hess, formerly representative of the Car Publishing Co., of Philadelphia, has resigned his position with that publication to accept one as general manager of the Car Equipment Company, of Philadelphia, with offices at 741 Drexel Building. This company will be exclusive agents for the Graham truck and Ajax metal for electrical purposes in the middle states and Ohio and the southern Atlantic states and will handle the product of the Allen Electric & Supply Co., Mr. Wm. A. Barrett, jr., is their president. Mr. Hess has a large acquaintance in the street railway field and no doubt will be as successful in his new venture as he has been in the past.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF ELECTRICAL PATENTS ISSUED FEBRUARY 20, 1894.

Alarms and Signals :—

Electric Bell Alarm, W. H. Orpen, Jr., Brooklyn, N. Y., 514,960. Filed Apl. 29, 1891.

Electrical Annunciator, N. M. Watson, Detroit, Mich., 514,975. Filed July 7, 1892.

Electric Signaling Between Railway Trains, J. J. Czepull, Lancaster Pa., 515,145. Filed Aug. 8, 1893.

An automatic electric block system giving a signal within the cab of the locomotive.

Conductors, Conduits and Insulators :—

Electric Cable, T. Guilleaume, Mulheim-on-the-Rhine, Germany, 514,925. Filed Oct. 6, 1893.

Consists of a body of grooved insulating material with electrical conductors lying in the groove.

Material for Insulating Electric Wires, G. A. Cannot, London, Eng., 515,192. Filed Sept. 22, 1893.

Consists of bitumen, peat fibre, spermaceti and tar.

Distribution :—

Transformer, F. S. Hunting, Fort Wayne, Ind., 514,933. Filed Feb. 25, 1892.

Has for its object to produce one or more independent currents of differing phase from two or more alternating currents of differing phase.

Electrical Converter, A. L Riker, New York, 515,020. Filed July 27, 1893.

Relates to the form of the stampings used for building up the converter core.

Electric Distribution Box, O. D. and M. A. Kleinsteuber, Milwaukee, Wis., 515,087. Filed June 27, 1893.

Relates to certain details of coustruction in distribution boxes for underground cables.

Dynamos and Motors :—

Alternating Current Motor, C. S. Bradley, Avon, N. Y., 514,902. Filed Sept. 27, 1892.

Employs two secondary elements, one of high and the other of low resistance and means for shifting them so that a single primary element may co-operate with either secondary.

Alternating Current Electric Motor, C. S. Bradley, Avon, N. Y., 514,903. Filed Sept. 27, 1892.

Has one element wound to develop progressively shifting magnetic poles and the other provided with a closed secondary circuit inductively related to the shifting poles.

Alternating Current Motor, C. S. Bradley, Avon, N. Y., 514,904. Filed Jan. 14, 1893.

Has two armature circuits one of which is an inductive circuit continually closed upon itself, while the other is connected with the source of supply through a re-directing commutator producing constant polarization of the armature core at synchronous speed.

Dynamo Electric Machine, C. F. Brush, Cleveland, O., 514,907. Filed Jan. 14, 1879.

Claim 2 follows :

An alternating current generator comprising two series of field magnets, coreless coils or folds mounted on a diamagnetic carrier, and a shaft having insulating material interposed between its sections.

Dynamo or Electric Motor, L. Gutmann, Pittsburgh, Pa., 515,216. Filed Feb. 13, 1892.

Employs field magnets arranged in two parallel core structures and armature cores rotating between the latter (See THE ELECTRICAL ENGINEER, Feb. 21, 1894.)

Galvanic and Thermo-Electric Batteries :—

Battery, D. H. Wilson, Chicago, Ill., 514,979. Filed Sept. 8, 1893.

Claim 1 follows :—

In a primary battery the combination of zinc and copper plate with their broad surfaces exposed to each other, their exposed sides deeply corrugated, and a solution in which said plates are immersed.

Lamps and Appurtenances :—

Electric Arc Lamp, S. W. Rushmore, Brooklyn, N. Y., 515,022. Filed Feb. 20, 1893.

Employs a single electro-magnet in combination with an armature moving upon a central axis under the influence of both poles of the magnet, and a short train of gearing mounted in a frame pivoted upon an axis coincident with that of the armature.

Arc Lamp, W. O. Meissner, Chicago, Ill., 515,125. Filed Sept. 11, 1893.

Employs a clutch adapted to move the carbon rod in either direction and an electro-magnet controlling the clutch.

Electric Arc Lamp, B. Ford, Johnstown, Pa., 515,205. Filed Dec. 8, 1892.

Relates to certain modifications of the clutching mechanism.

Measurement :—

Electrical Meter, N. Tesla, New York, 514,973. Filed Dec. 15, 1893.

Consists in maintaining by an alternating current a high tension discharge through a rarefied gas between two conductors and computing the energy expended by the amount of material thrown off from the conductors by the action of the discharge.

Miscellaneous :—

Switchboard System, D. H. Wilson, Chicago, Ill., 514,980. Filed Sept. 8, 1893.

Designed for use in connection with an "electric fence" system, *i. e.*, a metallic fence so arranged that an animal coming in contact therewith will receive a shock through its body.

Circuit Making and Breaking Device, D. H. Wilson, Chicago, Ill., 514,981. Filed Sept. 8, 1893.

Relates to automatically operated circuit closers for induction coils.

Electric Elevator Brake, A. J. Shaw, Muskegon, Mich., 515,255. Filed Oct. 24, 1893.

Electric Elevator Brake, A. J. Shaw, Muskegon, Mich., 515,256. Filed Nov. 4, 1893.

Electric Elevator Brake, G. A. Brown, Muskegon, Mich., 515,281. Filed Oct. 18, 1893.

Electric Steering Gear, F. L. Dyer, Washington, D. C., 515,286. Filed April 17, 1893.

Electric Igniter for Gas Engines, J. Low and J. W. Gow, Steubenville, Ohio, 515,297. Filed May 13, 1893.

Metal Working :—

Process of Coating Metals with Oxides, C. R. Arnold, Sharon Hill, Pa., 514,896. Filed Apl. 29, 1893.

Railways and Appliances :—

Trolley Wire Support, R. M. Hunter, Philadelphia, Pa., 514,962. Filed June 30, 1893.

Employs a supporting structure arranged upon the under side of the trolley wire and attached to the span wire.

Electric Railway System, N. Tesla, New York, 514,972. Filed Jan. 2, 1892.

Claim 1 follows :

In an electric railroad system operated by electric currents of high potential and frequency, the combination of an insulated and electrically screened supplying conductor extending along the line of travel, a motor car or cars carrying a conductor plate or bar in inductive relation to the screened conductor and an electrical connection between the said plate and the motor.

Electric Railway Conduit, M. S. Towson, Cleveland, O., 515,179. Filed Jan. 6, 1893.

Claim 1 follows :

The combination with a slot rail of a conductor, suspended from said slot rail by fastenings passing through the foot of the rail.

Trolley Conductor and Support, M. D. Law, Washington, D. C., 515,238. Filed Aug. 29, 1893.

Especially designed for use in connection with the Love conduit system. (See THE ELECTRICAL ENGINEER, Feb. 28, 1894.)

Indicator for Electric Cars, H. C. Beckmann, St. Louis, Mo., 515,274. Filed Aug. 17, 1893.

An electric station indicator actuated by current from the trolley wire.

Electric Railway Trolley, C. J. Van Depoele, dec'd., Lynn, Mass., 515,306. Filed June 18, 1888.

An under running trolley on a pivoted support.

Switches and Cut-Outs :—

Rheostat, J. B. Lyon, Brooklyn, N. Y., 515,241. Filed Dec. 22, 1891.

Claim 1 follows :—

A rheostat consisting of the combination of a resistance medium and a pair of electrodes geared together and movable with respect to each other.

Rheostat, A. J. Shaw, Muskegon, Mich., 515,251. Filed Oct. 13, 1893.

An open frame with a wire wound about it and connected with it at one end but insulated from it at all other points.

Rheostat, G. A. Brown, Muskegon, Mich., 514,280. Filed Aug. 19, 1893.

Claim 1 follows :—

A resistance card or body composed of a strip or band of metal folded back and forth upon itself,—the folds being separated only by the scale of oxide formed upon their faces.

Rheostat, A. J. Shaw, Muskegon. Mich., 515.304. Filed Oct. 13, 1893.

Consists of a band wound in a flat spiral whose convolutions are separated by a layer of enamel.

Telephones and Apparatus :—

Cushion for Telephone Receivers, V. A. Cook, Averill Park, N. Y., 514,913. Filed Nov. 28, 1893.

A pneumatic annular cushion adapted to be fastened upon the face of the receiver. (See THE ELECTRICAL ENGINEER, Feb. 28, 1894.)

Telephone, D. Drawbaugh, Eberly's Mill, Pa., 514,916. Filed July 26, 1880.

Employs a diaphragm carrying two electrodes insulated from each other, and an opposing electrode held against the former electrodes by an electric pressure device.

Telephone Transmitter, P. Fitzsimons, Birmingham, Ala., 514,920. Filed June 14, 1893.

Relates especially to the arrangement of the vibratory elements and their connections and to the employment of a non-vibratory support.

Electrical Circuit Controller, R. Callender, Brantford, Can., 515,108 Filed Nov. 2, 1893.

Employs a series of radically disposed plungers adapted to be moved into electrical connection with a common conductor, and a revolving arm carrying an electro-magnet for actuating the plungers.

Electrical Circuit Controller, R. Callender, Brantford, Can , 515,109. Filed Nov. 2, 1893.

Employs two or more vibratory reed armatures actuated by a controlling electro-magnet, and means whereby two or more local circuits are independently controlled by the reed armatures at the termination of their individual vibratory periods.

Automatic Signaling Transmitter, R. Callender, Brantford, Can., 515,110. Filed Nov. 2, 1893.

Employs a controlling commutator and a rotary circuit making and breaking device timed to have a definite relative speed of rotation; means for giving the circuit closer any number of revolutions, and for varying the number of closers in each revolution

THE OHIO BRASS COMPANY.

THE OHIO BRASS COMPANY, of Mansfield, Ohio, have just issued a well printed and well filled 84 page catalogue describing and illustrating about 250 of the electric street railway specialties of their manufacture. The company's devices are all thoroughly tested for electrical and mechanical defects, and are approved by their engineering department before being sent out.

The tendency of the times is to specialize on one line of work, and the Ohio company have recognized this fact in confining themselves to the street railway field exclusively, realizing that a greater degree of perfection in the manufacture of goods, can be arrived at in this manner. Their facilities for the manufacture of special devices, are unexcelled, and although heretofore they have not been brought directly into contact with those who purchase for the street railway companies, yet they have been manufacturing construction material during the past few years for one of the largest supply companies in the West, and their products are now in use on many of the largest roads in the country.

The catalogue is well arranged and is furnished with a good index.

The R. Thomas & Sons Company, of East Liverpool, Ohio, manufacturers of hard vitrious porcelain electrical supplies, have issued their catalogue, No. 3, containing 36 pages of beautiful full size reproductions of their specialties in white against a solid dark bronze background. No text is given, as the illustrations are so perfect that none is required, and the insulators, fuse blocks, rosettes and what not stand out so boldly that one is tempted to use them as they are instead of ordering real ones from the makers. In order to provide for the latter alternative, however, the company have offices at 136 Liberty street, this city, and 115 Dearborn street, Chicago, in addition to their general office and works at East Liverpool, Ohio.

Trade Notes and Novelties

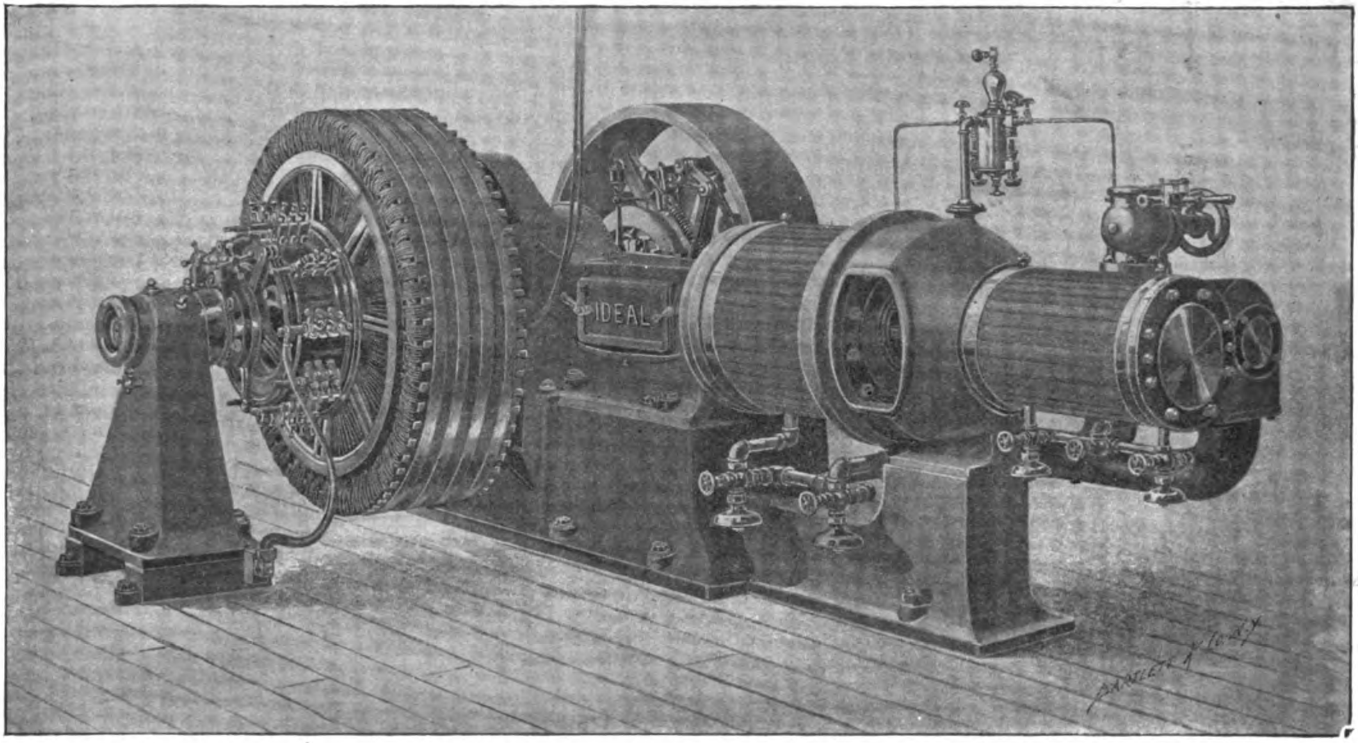
AND MECHANICAL DEPARTMENT.

DIRECT CONNECTED "IDEAL" ENGINES.

The direct connected combination of engine and dynamo of to-day is demonstrating by an increasing number of plants, its practicability, efficiency, and sound principles. The accompanying illustration shows perhaps the most modern of these combinations yet produced. This comprises a multipolar dynamo of the Waddell-Entz type, driven by a Harrisburg tandem compound Ideal self-oiling engine. The dynamo is 80 k. w. capacity and the engine cylinders are 10 and 17 inches in diameter by 12 inches stroke built in this instance for running non-condensing. The speed of the combination is 260 r. p. m. under a pressure of 115 to 125 lbs.

The Ideal engine as now manufactured has several important improvements. The self-oiling feature is a highly efficient device, supplying all the bearing surfaces with continuous streams of oil. Perfect circulation of oil is thus had without the care and attention dependent on drop feed or other oiling devices. The important bearing surfaces are dust-proof, and there is freedom from all splashing and dripping of oil. In direct connected work of this character, it is extremely important that the dynamos should be kept as free from oil as possible, as short circuits are often traced to the neglecting of this precaution. The remarkable simplicity and strength of the machine will be noticed, and the method of support under the cylinders is considered especially good by the makers. With this combination a water consumption is claimed in service of 23 pounds per h. p. non-condensing.

The engine shown is the product of the Harrisburg Foundry and Machine Works, of Harrisburg, Penna., and was ordered and installed at the Bridgeport Copper Company's Works by their representatives for New York and Boston, W. R. Fleming & Co., 203 Broadway, New York, and 620 Atlantic Ave., Boston.



HARRISBURG IDEAL ENGINE AND WADDELL-ENTZ GENERATOR.

THE "STRAIGHT LINE" centrifugal separator and grease extractor is one of the most popular devices of the kind now upon the market. It is used by a large number of electric light and power stations, railroads, and manufacturing plants generally, Joseph De Rycke, sole manufacturer, reports a brisk trade.

SAMSON ARC-LIGHT TROLLEY AND ARMOR CORD.

The Samson Cordage Works, of 115 Congress street, Boston, write that Samson braided cord has now become the standard for the suspension of arc lamps, and is no less in demand for street car trolley cord, and armor cord for covering field magnets of dynamos. The size most frequently used for hanging arc lamps is No. 12 (⅜-inch diameter); for trolley cord No. 8 (¼-inch diameter), and for armor cord, No. 4 (⅛-inch diameter). Unless otherwise ordered, the waterproofed finish is always applied to the arc-lamp cord and the trolley cord, and they are put up in coils of about 1,000 feet each.

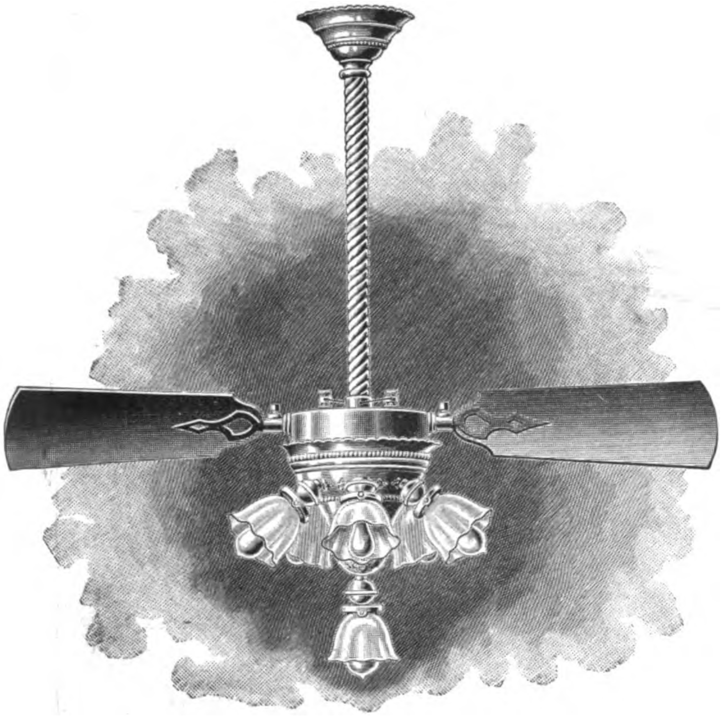
When desired, the company furnish their "Samson Spot Cord" which is the same quality and price as the plain Samson cord but marked with a succession of spots of a different color from the body of the cord. This device is trade-marked, and is for the purpose of identifying at sight the first quality cord. There is now on the market, it is said, a quantity of low grade braided cord which does not possess the strength or durability which is requisite for these purposes. All Samson cord is warranted of pure stock, perfect braid, and to be entirely free from waste stock, and purchasers may have confidence that the "spot" is a guarantee of quality.

MR. EDWARD M. BENTLEY, formerly the inventor and engineer of the Bentley-Knight Electric Railway Company, who has been for the past four years and a half in charge of the Patent Department of the Thomson-Houston Electric Company and the General Electric Company, has severed his connection with the latter company and opened an office at 40 Water street, Boston, taking up the work of expert in patent cases and solicitor of patents. The law firm of Bentley & Blodgett with which Mr. Bentley, who is a member of the bar as well as an expert, has been connected, will be dissolved, and his former partner, Mr. G. R. Blodgett, will succeed him as head of the Patent Department of the General Electric Company, making his headquarters at Schenectady.

THE roof for the new electric light station for the Citizens' Electric Light, Heat & Power Co., at Lancaster, Pa., is to be furnished by The Berlin Iron Bridge Co., of East Berlin, Conn.

THE DIEHL ELECTROLIER FAN.

Messrs. Diehl & Co., of 385 Broadway, are placing upon the market for the coming season a novel device; an electrolier-fan, combining the two. As shown in the illustration it is handsomely designed and finished, and both fan and lights can be operated independently or together, as desired. The Diehl apparatus is already so well known that no further description is necessary in regard to this combination, which will doubtless become popular as soon as the warm weather sets in.



Diehl Electrolier Fan.

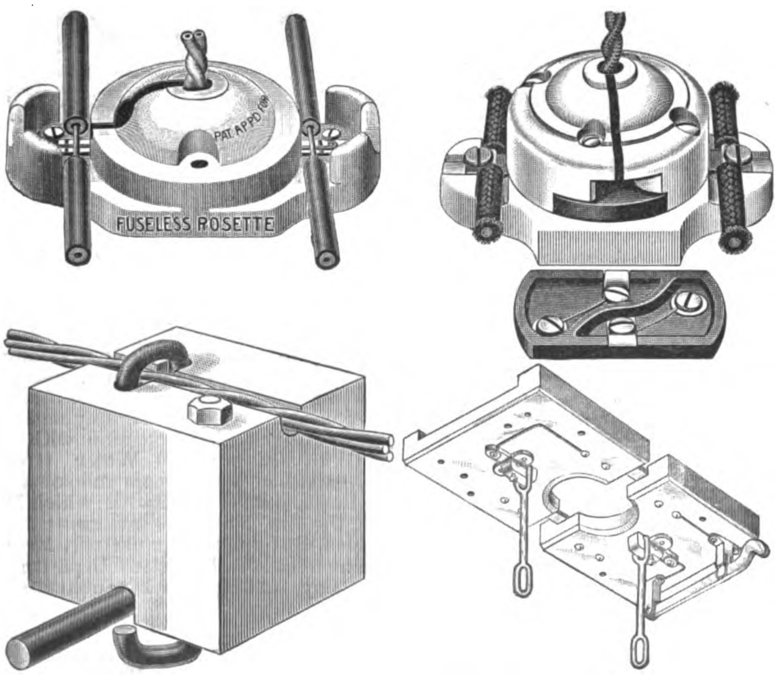
SOME NEW HAMMOND SPECIALTIES.

The Hammond Cleat & Insulator Co., of 15 Custom House street, Boston, have recently brought out several interesting specialties in porcelain insulators, rosettes, etc., some of the more noticeable of which are shown in the accompanying illustrations.

Fig. 1 shows the fuseless rosette made in one piece with a solid back, and therefore perfectly fire and waterproof. The cord is easily attached and there are only two screws in the entire device. The double pole fused rosette, Fig. 2, has its cover and base in one piece and hence affords no chance for a loose contact, while, like the fuseless rosette, it is water and fireproof. It can be used for moulded or cleated work. The fuses, as will be seen, are attached to an interchangeable slide, independent of other connections. These slides may be kept, ready fused, for emergencies.

Fig. 3 shows the trolley guard insulator made of one piece of porcelain japanned black. It is so constructed that the slipping of the guard wire or span wire is impossible. It is easily attached and has no parts to loosen or drop, and can also be used as a strain insulator.

The adjustable arc light hanger board, Fig. 4, is said to be the only one which conforms to the rules of the Insurance Exchange. Being constructed entirely of porcelain and metal, it is moisture and fireproof, with all electrical parts in plain sight, and no concealed wires anywhere. This hanger board can be used on high or low potential circuits. For the former it is provided with a jack knife switch. It is furnished in two sizes, the distance between lamp contact terminals being adjustable from 5 to 8 inches, and from 9 to 12 inches, respectively.



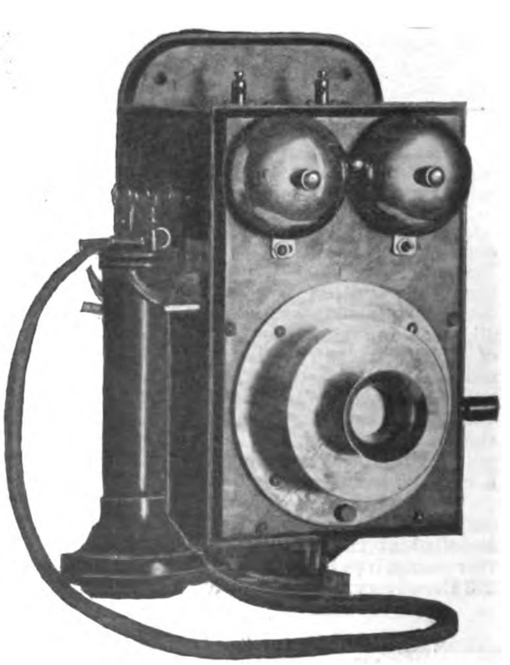
Figs. 1, 2, 3 and 4.—Hammond Rosettes, Insulator and Hanger Board.

THE WESTERN TELEPHONE CONSTRUCTION COMPANY'S APPARATUS.

Among the telephones placed upon the market since the expiration of the Bell receiver patent, the standard instrument of the Western Telephone Construction Company, Chicago, bids fair to take a prominent position among instruments of that kind.

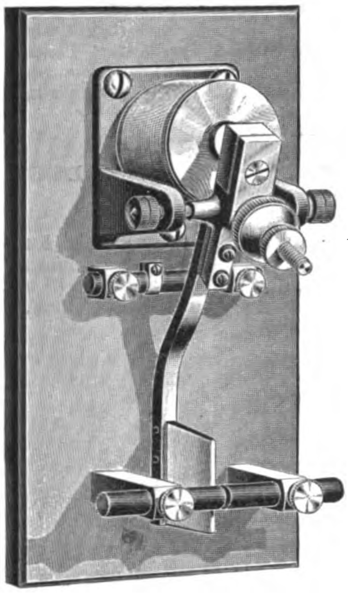
The accompanying engraving illustrates the instrument. It is of the magneto type in the strictest sense of the word, no battery whatever being used. The transmitter is attached to the face of the magneto bell used for signaling, and consists of a powerful steel magnet on the end of which is mounted a fine wire spool similar to the arrangement of an ordinary receiver. To guard against any deterioration of the magnet it is provided with a coil of wire and the current from the magneto is caused to flow through the coil, thereby strengthening the transmitter magnet every time the magneto is used. The transmitter diaphragm is made rather large and the pole of the magnet is provided with two polar extensions, so as to bring as much of the diaphragm as possible under the magnetic influence.

In a recent test of this instrument between Chicago and New York some very satisfactory results were obtained, the articulation being apparently as good as between two instruments only a block apart. The receiver is of the usual type and with the magneto bell and transmitter constitutes a complete equipment for one end of a line. There being no battery to take care of, the cost of maintenance is reduced to a minimum and the entire arrangement of the apparatus is so simple that no expert labor is required to put the instruments in successful operation. The company claim that the instruments furnished by them are fully covered by patents and do not infringe any patents not owned or not controlled by them.



The Western Telephone Construction Co.'s Magneto Transmitter.

THE DOANE LIGHTNING ARRESTER.



The Doane Lightning Arrester.

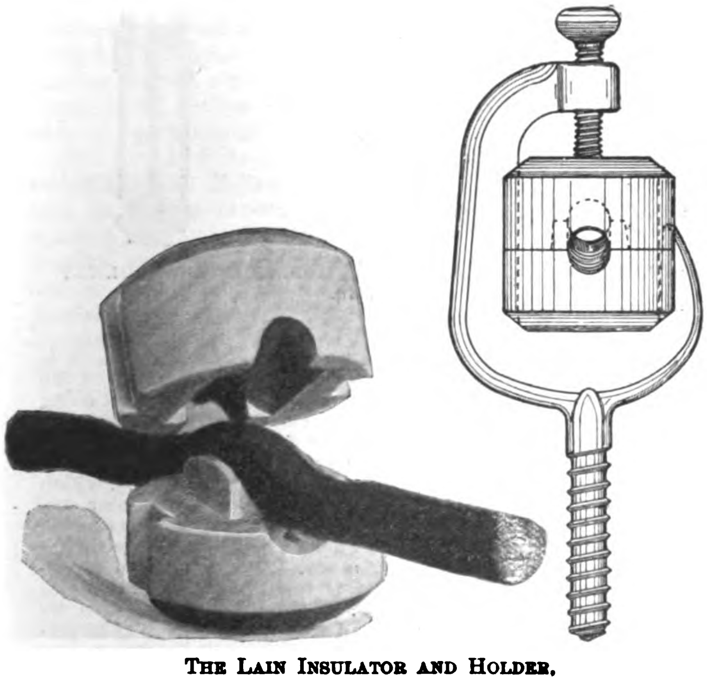
In the ordinary forms of lightning arresters the effect of a lightning discharge is to cause a short circuit of the line through the ground, by means of the arc that is formed across the carbon points of the arrester. This short circuit, although it exists only an instant, is oftentimes sufficient to cause damage to some portion of the electrical circuit, especially if the coils of an armature are embraced in it.

In the Doane arrester, shown in the accompanying illustration, and recently introduced by The W. S. Hill Electric Co., of 133 Oliver Street, Boston, the short circuit is made through a non-inductive resistance, sufficient to limit the current that will follow the lightning discharge, to an amount that cannot do any injury. In a 500 volt circuit, with a non-inductive resistance of 100 olms in series with the arc, only five amperes can follow the discharge. This can do no possible harm, and the arc formed by the passage between the carbons is easily extinguished and without injury to any portion of the circuit.

No current passes through any movable parts of this arrester, and with only a limited current through the carbons, they are practically indestructible.

THE LAIN INSULATOR.

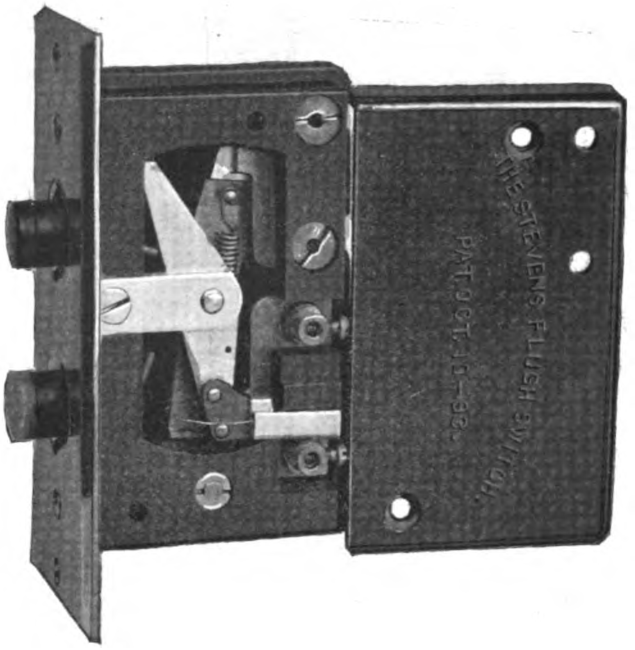
The Lain insulator, for which a patent has been granted to Mr. A. R. Lain, and which is being introduced by Mr. Robert E. Lain, of 115 Broadway, possesses several distinct features of novelty. The accompanying illustrations clearly show the simplicity of the device. It is made in two parts with a groove to hold the wire and the parts are fastened together by the socket that holds the insulator in place, so that no tie wires are required, and no chafing can take place. They are designed for electric light, telephone, fire alarm, and all other wires, from the largest to the smallest, and the socket, or holder is provided with either a spike or a screw as desired and can take any position on a pole. The absence of a tie wire is said to insure less leakage than ordinarily takes place, and the insulator is cheap, quickly put up, durable and convenient for transportation.



The Lain Insulator and Holder.

THE STEVENS FLUSH SWITCH.

The accompanying illustration shows a flush switch recently introduced by Mr. F. Stevens, 983 Chestnut street, Philadelphia, and containing a number of novel and interesting features. The switch occupies a mortise half an inch wide and three and a quarter inches long. The base is of vulcabeston and does not require to be opened for wiring, as the wires are not twisted about the screws but are simply pushed through holes in the case and fixed in position by screws whose heads appear upon the outside. The break is double pole and half an inch long and the switch is very easily operated by a slight pressure upon one of two buttons; a pearl one for switching the light on and a black one for breaking the circuit. These buttons, contrary to the usual practice, are both out at all times, though only one at a time is operative, and the mechanism is so arranged that but one spring is required for both levers. The switch is made in single, double and three-way patterns.



The Stevens Flush Switch.

PHILADELPHIA NOTES.

An electric light plant will soon be installed in the Star Theatre on 8th street.

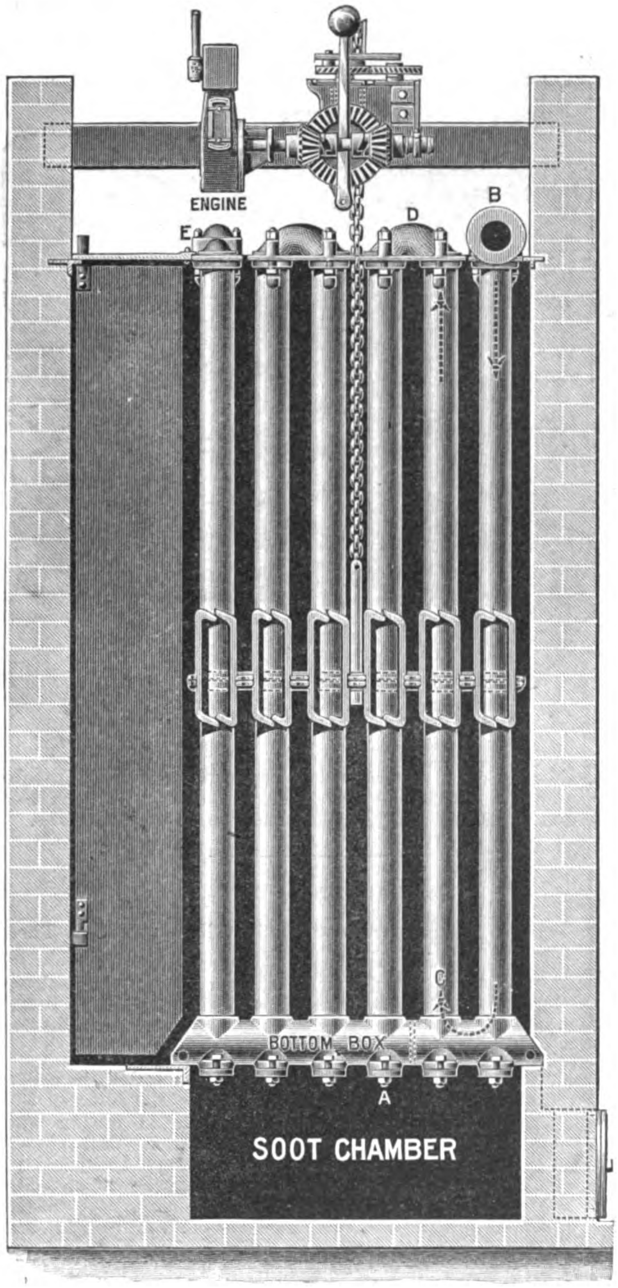
Mr. C. B. Crosby who for the past year has acted as salesman for the Harry S. Smith Co. has resigned his position to accept a similar one with W. C. McIntire & Co., who represent the Eddy Motor Co.

Harry S. Smith and Co., Ltd., have been awarded the contract for the electric light and signal systems from the Bank of North America, 309 Chestnut street, Philadelphia. All wiring will be run in brass covered Interior Conduit; insulation on all wires will be rubber covered, manufactured by the Safety Insulated Wire and Cable Co., of New York, for whom Harry S. Smith and Co. are the Philadelphia agents. The electrical work will be complete in every respect and the contract includes bell and burglar alarm work, watchman's clock, etc.

The Phila. Engineering Works, Ltd., have received an order for one of their Corliss winding engines, from the Chamberlain Coal Co., of Pottsville, Pa., Francis A. Pocock, engineer. This winding engine has 34-inch steam cylinders, 60 inch stroke to be operated by steam at 125 pounds pressure to the square inch generated by a battery of Stirling boilers. The engine is to be of the standard Philadelphia Corliss liberating valve gear controlled by a sensitive governor of the "Porter" type, and is provided with the Stevenson link, reversed by steam gear with an oil cataract. The hoisting drums are 10 feet in diameter, 10 feet long with powerful hand and steam brakes. The adjustment of the lift is effected by a toothed gear clutch, thrown in and out with worm gearing. The main shaft bearings are 17 inches in diameter by 30 inches long and the body of the shaft between the bearings is 19 inches in diameter, the central bearing being 19 x 30 inches. The engine is to lift an unbalanced load of 50,000 pounds at the rate of 1,000 feet per minute, and, with the drums will weigh about 325,000 pounds.

THE HIRT ECONOMIZER.

The Hon. Edward Atkinson, in the course of an address delivered before the New England Cotton Manufacturers' Association a little more than a year ago, predicted that the time would come when tall chimneys would stand as monuments to ignorance and wasted material. In view of the intense interest now being taken in scientific devices for economizing fuel and the general adoption of forced draft in the more carefully designed modern boiler plants, Mr. Atkinson's prophecy seems to stand a fair chance of fulfillment.



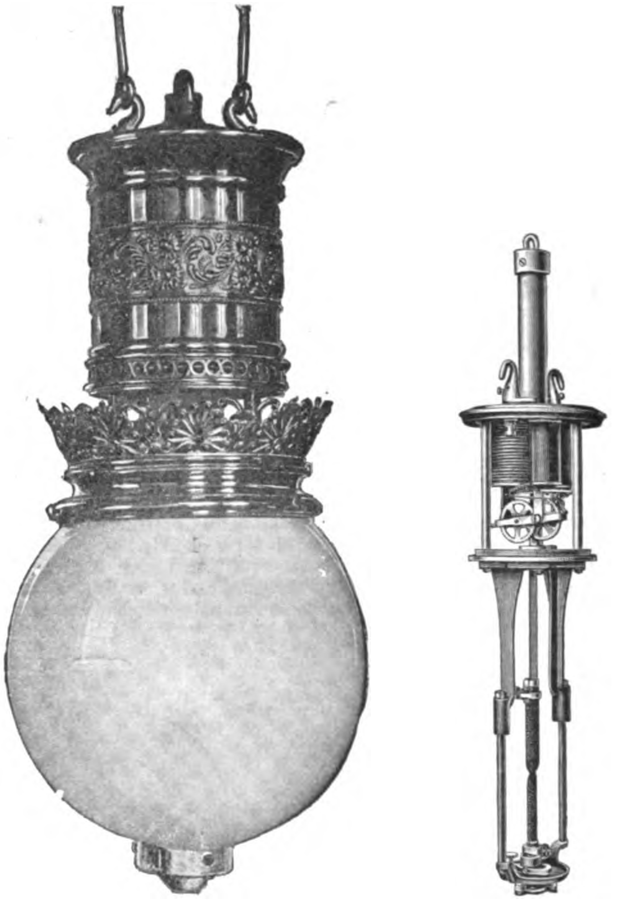
THE HIRT ECONOMIZER.

The accompanying illustration shows Hirt's patent fuel economizer, designed by Mr. L. J. Hirt, master mechanic of the West End Railway Company, in Boston. It is manufactured by the Consolidated Economizer Co., of No. 8 Oliver street, Boston, and intended for use in connection with their "Hawkins" mechanical draft apparatus, shown in their advertisement on another page. It frequently occurs in devices of this nature that, although the feed water is supposed to pass on its way to boilers, through a great number of tubes exposed to the heat of the waste gases, the construction is such that the circulation is, in reality, confined to but a few of the whole number, and the water reaches the boiler comparatively cold. With the Hirt economizer, however, this cannot occur. The water, as will be seen, enters at B and passes through the whole series of pipes, one after the other. The bend E leads to the next section, and so on throughout the whole nest. The bottom box is divided into sections as shown at C, and, to allow for expansion, no top box is employed.

The pipes may be easily and quickly cleaned, both inside and out, and the entire mechanical construction is excellent. There is a total length of 2,016 feet of pipe through which the water must pass and the efficiency of the device is, therefore very high.

THE NEW THOMSON ARC LAMP FOR INCANDESCENT AND RAILWAY CIRCUITS.

The General Electric Company announce a new arc lamp for incandescent and railway constant potential circuits. This lamp is known as the Thomson '93 arc lamp, and is the adaptation of a principle and construction patented some years ago by Prof. Elihu Thomson.



NEW THOMSON ARC LAMP FOR INCANDESCENT AND RAILWAY CIRCUITS.

The Thomson '93 arc lamp is a geared lamp but has, it is claimed, all the advantages of a clutch lamp. The feeding of the lamp is entirely independent of the weight of the carbon; it being equally regular whether with a whole carbon or one partly consumed. The lamp burns a very steady arc, noticeably free from noise, and instantly adjusts itself to any variation of potential. The principle of the feed mechanism is that of the rack rod, which carries the upper carbon-holder. This rod is of rectangular section; the rack meshes into the teeth of a pinion on an arbor in the case. This arbor also carries a gear which engages with the second pinion on the controlling arbor. Any downward movement of the rack-rod and carbon is regulated by a pawl and ratchet wheel on the second arbor. The pawl is controlled by the shunt magnet of the lamp, and the design is such as to permit a single tooth only to pass at one movement. The movements can, however, follow each other so rapidly as to allow a practically continuous feed, until the proper length of arc is obtained. The series magnet in the lamp acts to draw and maintain the arc. The lamps are adjusted for nine amperes of current with a 45 volt arc, but can be furnished for any current from 4 amperes upwards on special order.

At present four varieties of this lamp have been designed by the General Electric Company and are now ready for delivery; that for the alternating circuit is nearly completed.

THE
Electrical Engineer.

Vol. XVII. MARCH 14, 1894. No. 306.

THE ELECTRIC RAILWAY AND ILLUMINATING PLANT OF THE MILWAUKEE STREET RAILWAY COMPANY.—I.

BY

Otto Frick

By far the most prominent electrical feature of Milwaukee is the strong consolidation of the illuminating and street railway enterprises promoted by the Villard syndicate. Having acquired the old Milwaukee City and Cream City lines in August, 1890, this syndicate formed the Milwaukee Street Railway Company for the purpose of intrducing an electric railway service throughout the city, and the Edison Electric Illuminating Company, already established, was also absorbed. Later on the Badger Illuminating Company, interested in arc lighting solely, became incorporated with the others, though retaining its former name and its own management; recently the "Hinsey" line has also been acquired, and in the near future the West Side Road, or Becker Line, will cease to exist as a separate concern.

The Badger company is technically independent of the other services, and its very extensive arc light system may be the subject of a separate study, while the following description is confined to the street railway and Edison illuminating plants, for which a common power-house has been constructed with a common management and service, capable of operating all of the above installations.

The Power House; Site and Building.—Between River street and the Milwaukee River in the centre of the business quarter a favorable site, 105 feet by 115 feet, was secured for the power station at the electrical centre of the original survey, both as regards lighting and railway operations. The building, which covers nearly the whole site, presents a very plain businesslike exterior, as shown in the engraving, Fig. 1, and is of very substantial construction, utilizing the available space to the utmost.

The foundations are of concrete, carried on heavy piling and the walls are of brick with granite trimmings, and extra heavy. The north and south walls, which have to carry a great part of the weight of the engine plant on the third floor, measure, up to this floor, 40 inches in thickness, and 20 inches from this floor upward. The two front walls, east and west, have a thickness of 24 inches throughout. A heavy 48 inch brick wall erected through the centre of building is the main support of the third floor, which is formed by extra heavy 4 foot plate beams, placed 8 feet apart, the intervals being filled with cement on arches of brick and corrugated sheet iron. It looks like extravagance to locate heavy machinery 35 feet above the ground, but the problem is solved in a very satisfactory and successful way, without the necessity of procuring neighboring sites at exorbitant prices.

The dimensions of the building are 100 by 115 by 60 feet. The materials used throughout are stone and iron, thus making the whole building absolutely fire-proof. At each of the east and west walls a brick stack has been erected 125 feet high. The interior of the engine room walls is faced with white enameled brick which adds to the neat appearance as well as cleanliness of these rooms.

Lighting and Ventilation.—The building is, of course, lighted exclusively by incandescent lamps, the conductors being placed in the Interior Conduit and Insulation Company's metal covered conduits, carried on the inner surface of the walls. Ventilators run from the different floors to the roof of the building, and in addition large exhaust fans are placed to be used in extreme cases.

Space.—The problem of utilizing the available space has been solved in a most successful way which necessarily compelled a strictly systematic disposition of the different appliances. For instance, the free space in the basement, not required by foundations, is occupied by the condensing, circulating, heating and feed apparatus; north of the centre wall the railway engine room is two stories in height, while on the south side the boilers are arranged on two decks, or floors, leaving 4 feet from the south wall for coal bins, fed from the upper main coal storage bunker. The entire third floor has been reserved for the direct electric lighting and motor plant, with the exception of a 12-foot space at the south wall for this bunker.

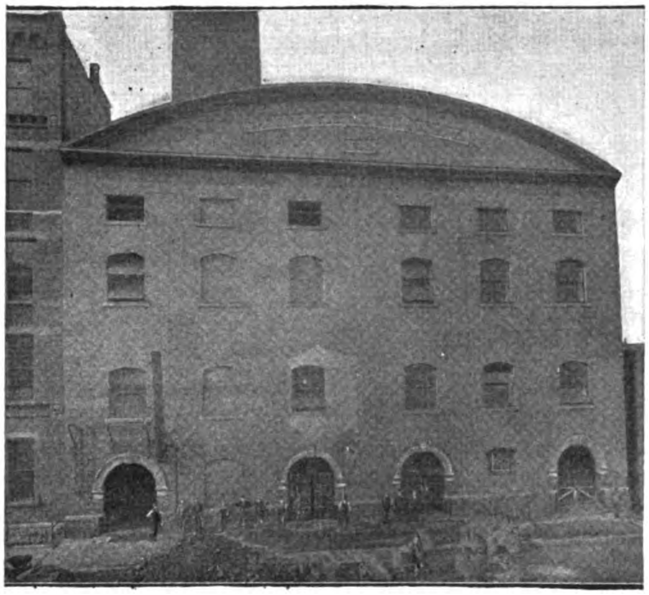


Fig 1.—Power House from River Street.

Condensing Plant—The arrangement and connections of the condensing and feed water piping will be readily understood from the diagram, Fig. 2. The condensing plants of the railway and electric light engines are totally independent of each other, the latter working on two main condensers, one a duplicate of the other, and each one individually capable of operating the whole present plant while space for two additional condensers, has been provided. Each of the railway engines has its own separate condenser, capable, however, of being thrown independently into connection with every other engine. These are all of the Wheeler surface condenser type, and are now, after two years' operation giving perfect satisfaction. The circulating water is taken from two wells on the dock front, communicating with the river through 16 inch pipes, by four Blake duplex circulating pumps, of 60,000 gallons capacity per hour each. Branches controlled by gates distribute the water to the different condensers, and all discharge back again into the river, the water being only raised 8 feet during the operation. The temperature is controlled to suit the conditions and the pumps are in duplicate. The exhaust steam from the engines passes through a grease separator of the centrifugal design that accumulates the grease and dirt and discharges it into an independent tank, thus preventing the fouling of the condenser and feed water.

Open Air Exhaust, Air Pumps and Hot Well.—An automatic relief valve is connected to the copper exhaust pipe before it enters the condensers, so placed that the exhaust can be delivered into a common exhaust pipe opening into a vertical exhaust 70 feet in height and 30 inches in diameter, located out of doors at the rear of the building, and fitted up with drains leading to the hot-well. The condensed products are taken through a 6-inch wrought iron pipe, connecting all the condensers in the railway plant and interchangeable in case of accident to any condenser, to four Blake air pumps, of a capacity of about 20,000 gallons per hour, discharging into a hot-well through a main 8-inch wrought iron pipe. The hot-well for the railway plant is circular, 16 feet in length and 4½ feet in diameter, constructed of steel plates and has a capacity of 1,600 gallons. In case of damage to the hot-well, however, the condensed water may be discharged directly into the river through an 8-inch pipe, also connected as an overflow from the top of the hot-well. All drains from engines, jackets, headers, etc., are led to the hot-well, as is also a direct steam discharge so that the temperature of the feed water can be kept at any point required and all possible heat of the feed water saved.

Elec. Engineer

FIG. 2.—DIAGRAM OF CONDENSING AND FEED PLANT.

Lighting Condensing Plant.—The condensers for the electric lighting plant, as before stated, are in duplicate, built beneath the sidewalk in front of the building. They consist of two large Wheeler condensers, supplied by two Blake tandem compound circulating pumps, each having a capacity of about 200,000 gallons per hour, and two Blake 50,000 gallon air pumps. The circulating water is taken in the same way as for the railway engines, through 24-inch pipes, and discharged back into the river through Vitrite pipes 30 inches in diameter.

Lighting Plant.—The lighting plant is on the upper floor and the engines and dynamos are of the same style as those of the railway plant, arranged with oil separators and exhaust piping as shown in Fig. 3. Automatic relief valves, similar to those used on railway engines, connect with the main open-air exhaust. The condensers for the lighting engines discharge into a separate hot-well 22 feet in length, with a capacity of 2,200 gallons, fitted up in a similar manner to the hot-well of the railway plant. The average vacuum maintained at the engines is from 23 to 25 inches.

Feeding Plant.—To secure water for the feed pumps four different combinations have been provided: 1. Hot water is taken from the hot-well; 2. City water can be used to fill the hot-well; 3. Through a by-pass on the condensers river water can be transferred from the water to the steam chamber; 4. The feed pumps can take water directly from the river. For each hot-well two duplex feed pumps of 7,000 to 8,000 gallons capacity are connected each with a Wass grease, air and mud extractor. The water is taken from the hot-wells by 6-inch pipes and led to the pumps by 4-inch pipes; before reaching the extractors a safety escape is offered to the feed-water, allowing it to flow back in the suction pipe through 3-inch relief valves, thus allowing the feed pumps to be run at a steady rate of speed, no matter how the actual feeding at the boiler fronts is being operated. As shown in the diagram, two 4½-inch pipes start from the two extractors, belonging to the second hot-well, the one passing along the first floor boilers, the other along the second floor boilers. These meet and connect with the pipe from the two other pumps at the west end of the first floor boiler room. The boilers are connected by 2-inch pipes and valves to these headers and to the blow-off pipes, as indicated in Fig. 2. A secondary line has been provided for the first floor boilers of two 2½-inch pipes, running along the back of the boilers, and communicating with the railway feed pumps and pipe ends A at the front of the boilers, to guard against accident to the main feed pipes.

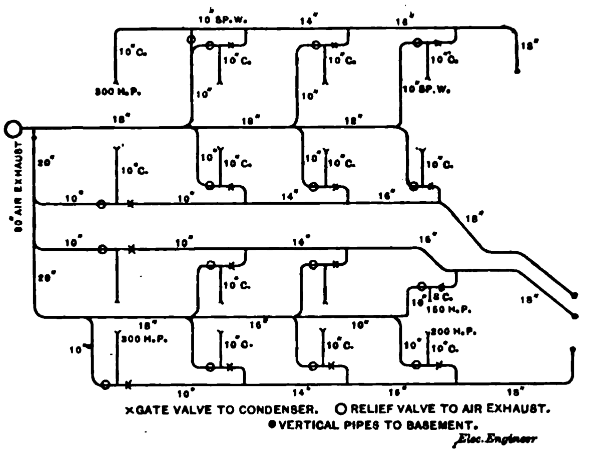

FIG. 3.—EXHAUST PIPING FOR LIGHTING ENGINES.

Boilers.—There are eighten boilers of the Galloway internal double flue type, with all the latest American improvements, manufactured with special reference to the work required, by the Edge-Moor Iron Company, of Edge Moor, Delaware, for a working pressure of 160 pounds, capable of generating 250 h. p. at 15 pounds per h. p. hour; this is the estimated quantity required for the triple compound engines of the Edison type at their maximum efficiency point. The boilers are 27 feet in length by 7 feet in diameter and have a flue space all around the shell enclosed with sheet iron, mineral wool and brick, making a very efficient battery. The flues of the boilers on each of the two floors are divided so that one half go to one stack and the other half to the other, thus allowing one quarter of the whole boiler plant to be repaired at any time when necessary without interfering with the operation of the rest. The arrangement is shown in Fig. 4. The boilers are also fitted with direct forced draft which can be used when necessary without interfering with the ordinary firing. Some of the boilers have now been in operation for over two years, and up to the present time have required absolutely no repairs; only one tube has started to leak and that was due to a blister in the material. It may also be here stated that at the time of adopting these boilers they were the only ones on the market capable of supplying steam at high working pressure.

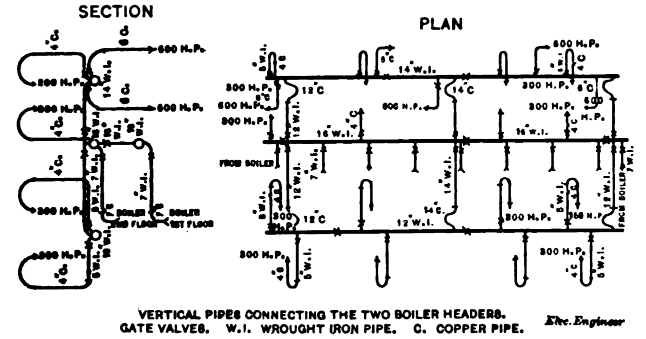

FIG. 5.—DIAGRAM OF STEAM PIPING.

Forced Draft—The stacks, being only 125 feet high on account of the unstable ground upon which they are built may, under unfavorable conditions prove insufficient to produce the necessary draft, and forced draft apparatus has accordingly been installed. This consists of four 60 inch fans driven by 5 x 4 inch double upright direct coupled steam engines, manufactured by B. F. Sturtevant, of Boston, Mass. The air is taken from the different parts of the building where heated air is likely to accumulate, thus greatly aiding the ventilation, and is forced into two large sheet iron conduits which connect under the fire-room directly with the furnace. The system is divided into two complete sections which are interchangeable.

Coal Storage and Ash Handling Apparatus.—The problem of storing and handling coal was a difficult one, owing to the contracted space available, and its solution has been remarkably happy. The coal is taken either from the street, where it is unloaded through an opening in the side-walk, into the basement, and lifted by elevators to the top floor, or, it may, by means of a second elevator on the river side, be directly hoisted from barges to the main large coal bin on the upper floor, whence it is distributed by a reversible conveyer. From this bin, or bunker, it descends by gravity through small channels to the other bins alongside the south wall in front of the two boiler batteries, as shown in Fig. 4. The storing capacity of the bins is about 600 tons. The ashes are taken away from the front of the boilers through conduits and delivered by elevators into bins at each end of the building where they descend by gravity either to wagons on the street or to barges on the river. The conveyers and elevators both for the coal storage and ash handling apparatus are driven by electric motors. The plant was installed by the Link-Belt Machinery Company, of Chicago, Ill.

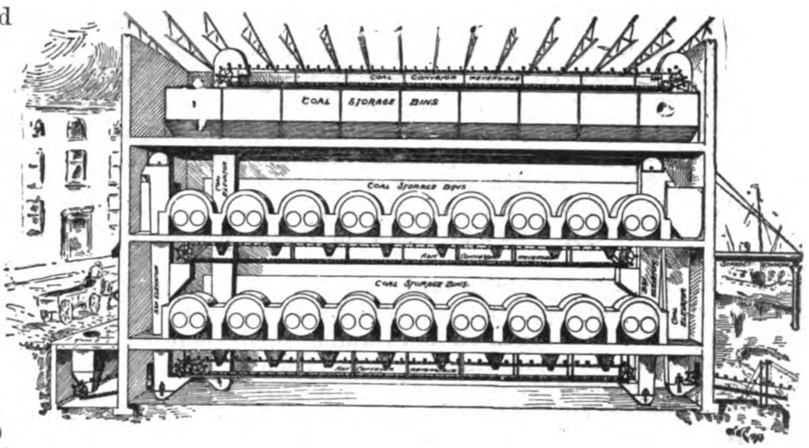

FIG. 4.—COAL STORING AND ASH HANDLING APPARATUS.

Steam Piping.—A diagram of the steam piping is shown in Fig. 5. The boilers are connected by 7 inch wrought iron pipes with large copper bends to two 16-inch headers, running along the south wall of the engine room and connected by three vertical pipes. From the upper header the steam is led to two sub-headers, 12 and 16 inches in diameter, respectively, from which it branches to the engines. Copper has been very extensively used to secure sufficient elasticity, and by well placed valves it is possible to shut off any part of the piping independently. Before entering the engines the steam passes through a centrifugal trap to be relieved from all entrained and condensed water. All flanges were specially designed for the high pressure used and are faced, turned and connected by fitted bolts. All joints are of brass wire gauze and litharge cement, and are in first class condition, and all piping and connections are covered with magnesia non-conducting blocks.

THE COPPER-ZINC ACCUMULATOR.—V.

(*Concluded.*)

D Paul Schoop

A NEW PROCESS OF MAKING COPPER ANODES WITH POROUS SURFACES.

As has already been set forth, the active material for the copper electrode, is applied *mechanically* to a copper support; while Desmazures uses spongy copper, which he applies by means of great pressure to a net-work of copper wire, Phillips and Entz make use of finely ground oxide of copper, which is pressed as a paste into the meshes of a copper cable. So far, both proceedings are very similar to the well-known process of "pasting" lead plates, covered by Faure's and Brush's patents. It might also be possible to render a copper electrode porous by an electrolytic process, similar to Planté's invention, for instance, but perhaps the best and most practical way is the following:

At ordinary temperatures, copper does not readily combine with oxygen, except in a very finely divided powder and the facility for combining increases at higher temperatures. Solid copper, either cast or wrought, begins to absorb oxygen at a temperature near 400 degrees C., and is covered by a black coating of oxide of copper. But this layer protects the subjacent copper from further contact with oxygen and prevents the deeper penetration of oxygen.

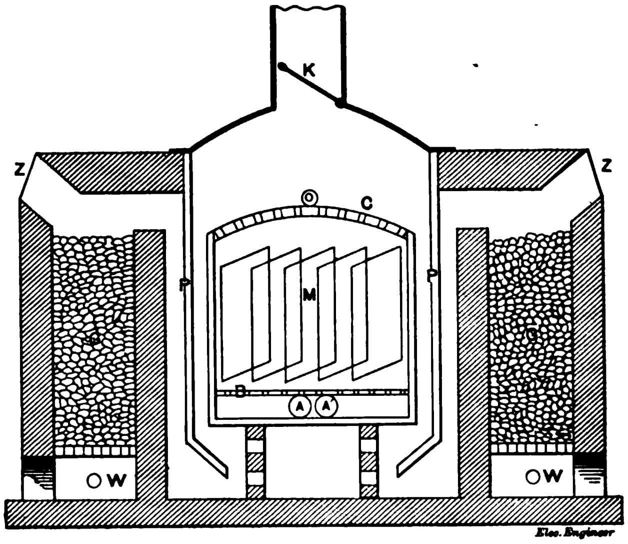
If the temperature is raised, say, to a full red heat, the black oxide of copper reacts upon the metallic support, giving part of the oxygen off and forming suboxide of copper. If now, at the same time, air or oxygen is permitted to circulate around the copper piece, the effect is that its surface can be oxidized to any desired depth; even so far that no more metallic copper is left, but the whole is transformed into oxide of copper.

This is not, however, what is wanted for our purpose. The surface should be oxidized to $\frac{1}{8}$ or $\frac{1}{16}$ of an inch and have a metallic support left of sufficient conducting power. To perform the desired result is a matter of maintaining the proper degree of heat; since the right temperature is very near the point where the oxide of copper fuses, some care has to be taken to prevent too high a temperature. One great drawback will be found, and that is, that while the article is cooling down, the oxide of copper blisters and cracks off; the contraction of the oxide of copper is different from that of the metallic copper and therefore the brittle oxide detaches itself from the metallic core. It is still possible, however, to attain a practical result. Before that point is reached at which the oxide cracks off the surface, it can be reduced to copper by contact with, for instance, carbonic oxide. The porous copper thus formed, adheres firmly to the solid core, and repeating the process once or twice, the porosity of the superficial layer can be brought to any desired degree. Of course, the second time, the temperature for effecting the combination with oxygen is much lower, only about 300 degrees C., and there is no more cracking off of oxide, or the temperature may be chosen so low as only to allow the formation of suboxide of copper; in this latter case the copper electrode is quite ready for use in the accumulator.

This process for making porous copper electrodes may be advantageously carried out with the aid of the apparatus described below, and which is shown in the diagram. In the centre of the cylindrical furnace is placed a muffle M of refractory material, such as magnesia or china clay. This muffle has a false, perforated bottom B and a perforated cover C. Below the false bottom there are two inlets A and A′; A is for the supply of air, A′ for the supply of carbonic oxide or generator gas.

P is a partition wall of insulating material, like asbestos or any other refractory substance. The generator G, which surrounds the muffle and partition wall is filled with coke by the supply-holes Z. A chimney K surmounts the generator. The copper is first put in the muffle and raised to the necessary red heat, while air is introduced through the inlet A. When the copper is sufficiently and uniformly oxidized, the air is stopped and the generator cooled down by blowing steam through the pipes W. At the proper time, the inlet A′ is opened and carbonic oxide or the water gas produced in the generator, is let into the muffle, where it reduces the copper oxide to porous copper. This operation is then repeated, but at much lower temperatures, in order to obtain the desired porosity of the layer.

After a little practice, it is possible to treat a large amount of copper each day in this way. The time of the whole treatment is about three hours. There is, perhaps, no cheaper and more rapid way for rendering copper porous, but there are still other interesting points connected with this method.



SCHOOP'S FURNACE FOR OXIDIZING COPPER.

1. The layer of porous copper adheres so firmly to the core of the electrode, that no mechanically applied layer could be compared with it. The copper may be bent many times and in all directions without detaching the layer.

2. The form of the copper electrode may be of any description, without interfering with the application of the porous layer. It need not be a wire netting or loosely made cable or a grid or any special form adapted to retain the active material firmly. For several reasons, a plain copper sheet is the most desirable form.

3. An electrode, made according to this process, does not infringe any patents, covering the mechanical application of active material to a support (paste, paint or cement).

4. The heating process must be cheaper than any electrolytic process, because no chemicals are used and the air and generator-gas are the cheapest agents possible.

5. The labor and hand work is almost entirely eliminated.

After the copper electrode has been treated, it must be covered or surrounded by a partition or membrane; since it is very doubtful whether organic substances like cotton (cellulose) or parchment paper (hydro-cellulose) are likely to stand the action of the strong caustic electrolyte without injury to the cell. The copper electrode is put preferably in a porous pot made of magnesia. The magnesia is entirely stable and may be made of any desired porosity. It may also be impregnated with substances that attract those traces of soluble copper compounds, occasionally formed, and thus impart to the copper accumulator that amount of reliability necessary for its practical success. Dolomite may also be used as material for the porous cup instead of magnesia.

UNDERWRITERS INSULATION REQUIREMENTS AND THEIR INFLUENCE ON THE QUALITY OF WIRES.

BY

H. C. Cushing Jr.

Every piece of insulated wire that is to be used for lighting or power purposes in the city of Boston has to be subjected to a very careful insulation test before it can be used in any building within the city limits. This test is made by the Boston Fire Underwriters Union, and a similar test has to be made for the New England Insurance Exchange before they will pass upon its use in any building in New England, outside of Boston. Although neither board can enforce the removal of a single piece of disapproved wire or wiring they can so add to the insurance rate on the building in which the wiring is done that the owner soon comes to the conclusion that there is really danger of fire and out comes the bad work which is replaced by good wire and good workmanship.

Electric lighting, as we all know, is the safest mode of illumination when properly installed; yet there is nothing so likely to set fire to a building as electricity when carelessly handled. With the knowledge of this fact the insurance companies, all over the country, have adopted rules which have been very carefully compiled by men of long and varied experience in electrical construction work and as every piece of wiring, either for lighting or power, is now thoroughly inspected before the current is turned on in the building, and due to the fact that we are getting better wire and fixtures every year, it is safe to say that there is no possible chance of a fire from electricity if the wireman and inspector does his duty according to the present rules and requirements.

Although we have had numerous makes of insulated wire for a number of years it is only within the last two years that we have had uniformly excellent wire insulation. Not that we have not always had the insulating material but the method of manufacture has been crude. Rule 12, of the Rules and Requirements of the Boston Fire Underwriters Union, state that :

> "Insulation that will be approved for interior conductors must be solid, at least $\frac{3}{64}$ of an inch in thickness and covered with a substantial braid. It must not readily carry fire, must show an insulation resistance of one megohm per mile after two weeks submersion in water at 70 degs. Fahrenheit, and three days submersion in lime water, with a current of 550 volts and after three minutes' electrification."

Every test on samples of insulated wire, furnished by over fifty manufacturers, has been kept on file by the Boston Fire Underwriters Union since March, 1888, and each year since then has shown a vast improvement over the previous year as to quality of wire, insulation, finish and power to withstand abrasion.

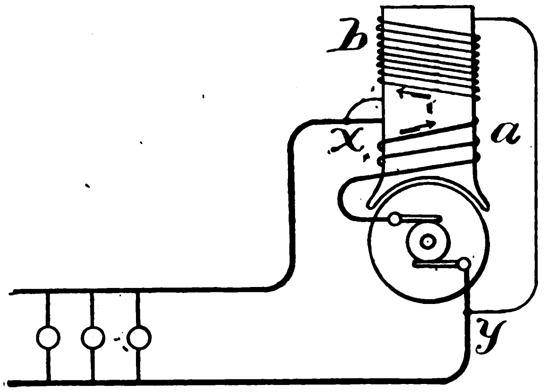
The samples of wire submitted in the year 1888 showed a very uncertain quality, the insulation showing a resistance of from 1800 megohms to 3.3 megohms per mile upon being submerged in water and many of the samples showed no resistance whatever after having been in water five or six days with only 140 volts used in making the measurements. This clearly showed the presence of pin holes, flaws and a non-homogeneous coating of the insulating material, a state of affairs that recent tests show to be rapidly disappearing with the modern improvements in manufacture to meet various requirements.

This inferior or uncertain quality of insulation continued to pour in until December, 1892, but from that date up to the present time a wonderful improvement has been noted and the tests on all samples, submitted by over fifteen different manufacturers, show that in no case has the insulation resistance dropped lower than 220 megohms, after having been submerged in water for fourteen days and then in lime paste for three days, and each reading being made with a potential of 550 volts; while several samples showed a resistance of over 4,400 megohms after the same severe test.

We thus see that the manufacturer has more than met the insurance requirements and it is certainly very gratifying to both parties to note the steady improvement in the manufacture of insulated wire upon which depends the safety of our buildings and the lives of our linemen, as the insulation requirements hold good for outside as well as interior conductors.

THE LEWIS SELF REGULATING CONSTANT POTENTIAL VARIABLE SPEED DYNAMO.

In recent issues we gave a description of the electric car lighting system of the Lewis Electric Co., and of their windmill plant designed as a source of electrical energy; both being operated in connection with storage batteries. In the one case we have a dynamo driven from the car axle and in the other by the windmill through gearing. The character of both these driving agents is identical in the variable nature of the speed to which the dynamo must necessarily be subjected and our readers will recall the fact that in those descriptions we stated that the inventor, Lieut. I. N. Lewis, U. S. A., had designed a very simple method for obtaining a constant potential at the battery terminals, without introducing any auxiliary regulating apparatus, which has heretofore so greatly retarded progress in this direction. We are now able to describe the method alluded to, which consists simply in a special method of winding the field magnets of the dynamo.



Lewis Constant Potential Variable Speed Dynamo.

In the ordinary method of compounding dynamos for constant potential where the driving speed is constant, the current in the series coil acts cumulatively with the shunt to maintain the strength of the field magnetism. To accomplish the maintenance of constant potential with *varying* speed, however, Lieut. Lewis simply reverses this order of things and connects the series coil differentially or reversely, so that its acts to demagnetize and weaken the field as the speed increases. The method will be readily understood by inspection of the accompanying diagram which shows the long shunt method of connection, the same principle of course holding true with the short shunt. The shunt coil is here shown at *b* and the regulating differential series coil at *a*.

The results obtained in practice with this method of winding are quite remarkable. In some recent tests with speeds varying between 600 and 800 revolutions and with current varying from 1 to 35 amperes, the potential did not vary more than 1 volt from the normal 35 volts for which the machine was designed. With such a machine available the problem of electric car lighting and windmill storage is in a fair way to find a speedy solution.

ELECTRIC TRANSPORTATION DEPARTMENT.

THE CHLORIDE ACCUMULATOR ON PARIS STREET RAILWAYS.

Some attempts at electric traction by accumulators have been made in these latter years in France as well as in other European countries but nearly everywhere this method of traction has been abandoned, principally on account of the failure of the system of accumulators employed. The Street Railway Company of Paris and the Department of the Seine once abandoned the system after a few months' use on its St. Denis lines. Now, however, it is no longer a question of mere experiment, but one of genuine industrial development. The installation of the St. Denis station has been made in view of the development of two lines, each about six miles in length. They both extend from the rond-point de Picardie at St. Denis, the one to the Madeleine, the other to the Opera. The first trials took place in February, 1892. Electric traction has been employed regularly on the portions of the two lines situated outside of the city walls since June 1st. Horse cars were entirely done away with on the Madeleine line October 1, and will shortly be abandoned on the Opera line. A third line, about three miles long, running from the mayoralty house of St. Ouen to Neuilly, will soon be operated by electric cars.

The plan laid out for the constructors of the motors and accumulators was to substitute for the horse cars on the two lines above designated, self-propelling cars, with seats on the roof, having a carrying capacity of fifty passengers and two company employees. The lowest speed imposed, with full car, was seven and a half miles per hour, with the possibility of attaining a speed of ten miles an hour outside of Paris, and a minimum rate of three and three-quarter miles on the heaviest grades, which are about four per cent. Moreover, the company reserved the right of attaching another car to the electric cars. The daily mileage of each car was to be at least sixty-five miles, and the weight of the accumulators, including all accessories, was not to exceed 6,000 pounds. All these conditions have been fulfilled to the letter.

The body of the car rests on rollers upon two trucks, each having one axle, and being held in place by a king bolt. These two trucks are bound together by a system of joints and springs, which allows the axles to converge on curves and restores them to parallelism on a straight track.

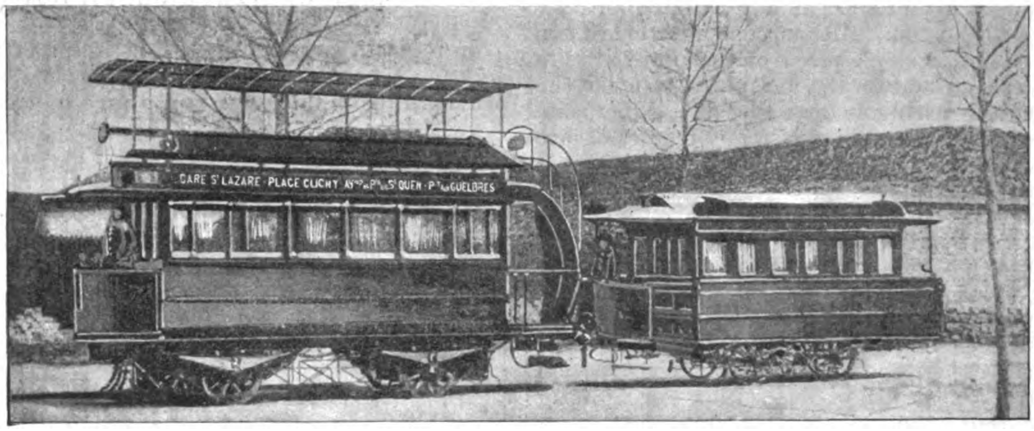
A motor is attached to each axle by double-reduction gear wheels, the ratio between motor and axle being twelve to one. The gears are in an iron casing, the first pair completely immersed in oil. The motors are bi-polar, of the Manchester type, with Gramme armature, series wound. The brushes are four carbon blocks. Each motor will develop, with a speed of 1,850 revolutions per minute, a power of 10,000 watts, with a difference of potential of 200 volts. Under these conditions the efficiency between motor and axle is seventy-three per cent. The trucks and motors were supplied by the firm of Averly, of Lyon, and M. Lemoine's roller brake is used.

The accumulators are of the chloride type, manufactured by the Société pour le Travail Electrique des Métaux, to the operation of which its distinguished director, M. Sarcia, has imparted a very remarkable impulse. The accumulators are placed under the seats of the car. There are one hundred and eight elements of eleven plates each contained in hard rubber boxes. The plates are seven and three-quarter inches by seven square and a quarter of an inch thick, and the weight of an element is thirty-eight and a half pounds. These one hundred and eight cells are divided into twelve groups of nine batteries each, contained in twelve wooden boxes, six on each side of the car, the batteries of each group being connected in series, and the two terminals attached to copper strips fastened to one of the partitions of the wooden box.

To the wooden props of the car are attached brass springs connected to the motor circuits, with intermediate regulating switches. The introduction of the boxes into the car causes these springs to slide on the copper strips and the circuit through the constituent parts of the battery is thus automatically established. The batteries are charged on a platform made of joists, covered with tar, supported by brick piles and supplied with glass insulators. These platforms have brass contact springs like those in the cars. The batteries when placed on the platform for charging are connected in series. The station for accumulators has space for twenty-four sets of batteries, each one connected to a distributing switchboard by a special circuit, in which is an ammeter, a polarity indicator, a double-pole circuit breaker and a make and break switch.

The transfer of the batteries between the charging tables and the cars is effected by means of small cars moving on tracks which run alongside of the platforms and the street car tracks. When a car returns to exchange its discharged battery for another, seven of these transfer cars are ranged on each side of the tracks, six carrying boxes of accumulators freshly charged and the seventh empty. The first box of batteries contained in the street car is slid on the empty transfer car by which it is carried to the place which it is to occupy on the charging platform. The first box of the new battery passes from its transfer car into the space in the street car thus left empty, and a second box of discharged battery is removed, and so on consecutively. The platform of the transfer car can be raised and lowered by a screw and fly wheel so that it can be brought to the level of the interior of the street car or of the charging platform. This is accomplished in five minutes or less.

The charging current for the accumulators is furnished by three Desroziers dynamos, constructed by the firm of Bréguet, each run by a one hundred and twenty-five horse-power Corliss horizontal condensing engine. Two of these engines run at a speed of seventy-five revolutions, and the third at one hundred and sixty revolutions. This last runs its dynamo by means of a single belt, the other two by intermediate shafting. The engines are supplied by three semi-tubular boilers. This plant was installed by M. E. Garnier.



PARIS STREET CAR OPERATED BY CHLORIDE ACCUMULATORS.

Each dynamo, at a speed of 600 revolutions, develops a current of 280 ampers, with an electromotive force of 260 volts, and the sets of accumulators are charged in parallel, with a constant electromotive force of 260 volts. The duration of the charge is six hours for a battery which has furnished all its capacity of 280 ampere hours, or fifty-two horse-power hours. The yield in energy of the batteries is as high as seventy per cent. The batteries in service, with an electromotive force of upwards of 200 volts, give a discharge, which on grades reaches seventy amperes, or nearly two amperes per pound of element. The average output on the level is about thirty-five amperes, which increases to fifty-five amperes on grades of two and a half per cent. One charge of the batteries will run the car about forty miles on grooved rails and about seventy-five miles on ordinary T rails.

In order to operate the car at the various speeds required in service the coupling of the cells of battery is changeable. In the car the batteries are divided into four parts, each of twenty-seven cells in series, which give, on closed circuit, about fifty volts. By means of a regulating switch, placed under the control of the driver, three couplings of batteries may be obtained of 50, 100, or 200 watts. The speed of the car is doubled in passing from one coupling to the other. The motors of the car are usually connected in series, but, by means of a switch, may be placed in parallel when greater speed or power is required. This second switch also reverses the direction of running of the car by reversing the current in the motor armatures, and by it also a motor may be cut out of service in case of damage by short circuiting on the series combination. A single motor is sufficient to run the car with a slightly reduced speed.

The switch for altering the coupling of the sub-batteries consists of a cylinder of non-conducting material, carrying three sets of copper strips, corresponding to the three couplings or combinations of the batteries. These strips become connected when the cylinder is revolved on its axis between the metallic brushes, communicating with the sub-batteries. In passing from one position to another the current is broken before the strips are released from between the brushes, the break being made on special strips supplied with blocks of carbon, so arranged as to be easily replaced. The barrel is revolved by means of a lever. The switch or regulator which changes the couplings of the motors is composed of three commutators, operated by separate cranks, which are so interlocked that they cannot be operated except when the current is broken by the battery switch.

The daily service on the Madeleine route (the only one at present entirely operated by electric cars), consists of one hundred and four trips, or fifty-two round trips. Seven cars are operated on this line, some making eight and others nine trips, about ninety-two and one hundred and three miles; while horse cars make not much more than sixty miles. Each car is operated with two sets of batteries, making from four to six consecutive trips, forty-six to sixty-nine miles without recharge. The running time between terminals is fifty-five minutes, including stops. The weight of a full car is about 29,000 pounds, of which 5,700 pounds are for the batteries and their accessories and 7,700 pounds for the passengers. The mean tractive force is about twenty-six and a half pounds per ton.

The average results of operation on the Madeleine line for October, November and December, 1892, per car mile are as follows: Ampere hours charged, 6.2; horse-power hours, generated, 2.2; coal consumed, 9.2 pounds; oil consumed, .015 pound. The averages for a whole year would be lower, as the average for the three months considered is relatively high in consequence of the heavy condition of the road due to mud, snow and ice. The road is built of T rails, weighing about fifty pounds to the yard, except in St. Denis and Paris, where the Broca grooved rail is used, weighing about ninety pounds to the yard. The service has been very regular and the receipts per car mile have increased to a marked degree, and the favor of the public has been instantly won by the new, comfortable cars lighted by electricity.

Encouraged by the good results obtained, the street car company has determined to introduce storage battery traction on their other lines. On the new cars, which are to be built, a system of regulation is to be employed whereby, in stopping the cars and in running down grades, the motors will become generators, and a portion of the energy previously given out by the accumulators restored. Great credit is due to the manager and directors of the street railway company through whose efforts and perseverance storage battery traction has triumphed in Paris, and will, it is thought, be speedily adopted throughout France.

BRISTOL AND TRENTON ELECTRIC RAILWAY.

The first link in the chain of electric railways which will eventually connect New York and Philadelphia is now well under way. The Philadelphia division between Bristol and Trenton, 34 miles in length has been surveyed and that section alone will include a mile of bridge work. The contracts for construction will soon be let. Mr. A. Langstaff Johnston, consulting engineer, has charge of the work, which will be pushed to early completion.

CAPACITY OF RAILWAY MOTORS.

BY

E. A. Merrill.

THE usual traction formula or table gives the draw-bar pull required to keep a given load in motion either at a very slow speed or at some specified speed and with a specified coefficient of resistance. While these tables are applicable at all speeds to locomotives and other engines where the tractive power may be kept constant and the power consumed varies directly with the speed for any given tractive power, they are not at all applicable to electric motors in which the tractive power is constantly varying independently of any method of motor control, and in which the energy utilized in propelling the load may be, and often is, very different from the total energy consumed.

To illustrate: A certain table gives .32 h. p. as the power required to propel 1 ton at a speed of 4 miles per hour, on a level, with a coefficient of resistance of 30; a 50 h. p. equipment should therefore be capable of propelling 156 tons at this speed without exceeding its rated h. p.; this might easily be true for a steam locomotive but is assuredly not for an electric motor which, if geared for a normal speed of 12 miles per hour, will reach its normal *ampere capacity* at 52 tons. The table is therefore unreliable and almost useless at all speeds and loads except those at which the motors will give their rated output.

The reason for this discrepancy is found in the fact that the tractive power of the locomotive can be varied widely and for indefinitely long periods without undue strains on the working parts, while electrical and mechanical limitations practically compel a maximum tractive power in the motor not far above its normal capacity except for very short periods; this tractive power, aside from magnetic variations in the iron, is dependent upon the ampere capacity of the motor windings and is practically the same for all speeds; therefore, as the coefficient of resistance in street railway work will not vary by any determinable amount for speeds up to 12 or 15 miles per hour, the maximum load that can be propelled at any speed will not exceed the maximum load that can be propelled at its rated speed so long as the normal tractive power is not exceeded; the speed will vary directly with the E. M. F. at the motor terminals.

This indicates a simple method of ascertaining what is more important than the total horse power consumed in moving the load, viz., the proportion of the normal tractive power which must be excited to move any given load, the rated horse power and normal speed of the motor at the E. M. F. of the line being known. For, from the horse power and speed at which that horse power will be developed the pull at the periphery can be determined and this pull is independent of all variations in wheels, gears, speed reductions or armature diameters, and also holds true per horse power for any size of motor.

If we know the ratio of tractive power exerted to normal tractive power we know pretty accurately how far the proper carrying capacity of the armature and field windings is being utilized or overloaded; the total horse-power consumed does not give the remotest indication of this important point. To determine this ratio the writer has used the following table which is presented with the hope that others may find it equally useful; it is based on the assumption that the rated horse-power of the motors can be applied at the periphery of the driving wheels at the rated speed without overheating fields or armatures.

LBS. PULL AT PERIPHERY OF WHEEL AT RATED H. P. AND SPEED.

To determine the maximum normal load in tons, divide the pounds pull by the resistance per ton; thus on a 10 per cent. grade the maximum normal load would be for a 50 H. P. equipment whose normal speed was 12 miles per hour: $\frac{1562}{30 + (10 \times 20)} =$ 6.8 tons.

The formula is: $\frac{\text{Lbs. pull}}{\text{Resistance}} =$ Load in Tons.

To get the ratio of tractive powers, divide the actual load by the normal load; thus, if the actual load is 10¼ tons the ratio is

$$\frac{10.25}{6.8} = 1.5,$$ or the motors are propelling a load which demands an increase in current above the normal sufficient to increase the normal tractive power by one-half.

On the above basis the following table has been figured, giving the tons that can be propelled per rated horse power without exceeding the normal tractive power. It will be noted that the speeds given are the normal speeds for which the motors are designed; the actual speed will take care of itself, varying with the actual load and the voltage at the motor terminals; the coefficient of resistance is assumed to be 30.

TONS PER RATED HORSE POWER AT PERIPHERY OF WHEELS WITH NORMAL TRACTIVE POWER.

THE PROPOSED 5,000 H. P. ALTERNATORS FOR NIAGARA.

THE latest number of the *Journal* of the English Institution of Electrical Engineers contains the illustrations accompanying the paper read by Prof. George Forbes before that body on "The Electrical Transmission of Power from Niagara Falls."[1] We give the illustrations of the machine characterized by Prof. Forbes as representative of the type to be employed at Niagara, together with the description.

On the bed-plate a vertical cylinder, A, Figs. 1 and 2, is bolted, with projections to support the fixed armature and the bearings of the revolving part. The armature coils, E and F, are wound independently, and can be removed and changed. They are fixed in slots, C, in the fixed armature. They are encased in an oil-tight casing through which oil can be circulated. The field magnet is external to the armature, and has the poles pointing radially inwards. It consists preferably of forged steel, supported by a spider, D, with eight arms, which may be of steel (shown as a bronze casting in the drawings) with a covering of thin sheet metal, on which cups are provided for forcing air into the interior of the machine. The pole-pieces are bolted on to the steel rim, B. The field coils are of copper strip, two coils being wound upon each pole, with a space between them for air circulation. The exciting current is applied by rings of tempered copper on the spider, having fixed brushes rubbing on them, shown at G. The hub of the spider is firmly fixed to the upper end of the shaft. The spider supports the heavy rim by 16 studs and nuts. The shaft is supported by two bearings, each of which has four radial arms, H, which are bolted to four corresponding projections on the cast-iron cylinder. This cast-iron cylinder is bolted to the bed-plate at I, and adjusted thereon by wedges. Besides having on it the projections for carrying the bearings on its inner side, it has on its outer periphery a series of vertical ribs, K, against which the stampings, or sheets of iron, forming the armature rest. It also supports the lower end plate, L, on which the armature is built up, and the armature is keyed to it by a single key. The armature is wound drum fashion —that is, all on the outside. This enables the coils to be wound independently and afterwards laid in their place, and also to be easily replaced in case of accident. In order to do this satisfactorily, the slots for each coil in the iron are cut, not radially, but parallel to each other, such as the two marked C in Fig. 2. Each coil is encased in insulating material, which forms a tube through which oil may flow as in a transformer, but may be forced, in which case its circulation is maintained by a pump. Round the base of the machine there are two oil pipes, A and B, one being the inlet, the other the outlet. These are seen in Fig. 3, which shows the improved oiling arrangements, which were worked out by Prof. Forbes' chief draughtsman at Niagara Falls, Mr. Baumann. The inlet pipe is connected with a reservoir of oil in the power house. The outlet pipe leads by another pipe to cooling arrangements in running water, from which the oil is pumped to the reservoir. From the inlet pipe 16 brass tubes, C, are led to the junction boxes at the bottom of the 16 coils; the 16 other brass tubes, D, are led from the junction boxes at the top of the coils, through the interior of the fixed armature, and bent over the foundation plate, and so connected to the outlet pipe which surrounds the bed-plate. The outlet pipe is broken at E, a cup being placed on the lower part to catch the oil as it issues from the upper part, so that the rate of flow of the oil may be seen. The bed-plate is a single iron casting, and, in order to enable it to be transported over the railways, it was necessary to limit its diameter, as shown in Fig. 3. The armature is built up of thin sheet iron, with ventilating spaces, as shown on the drawings. The bolts which hold the armature together are eight in number, made of nickel steel, a metal which has the great advantage of being non-magnetic, and of very high electrical resistance and great mechanical strength. The amount of nickel is 25 per cent.

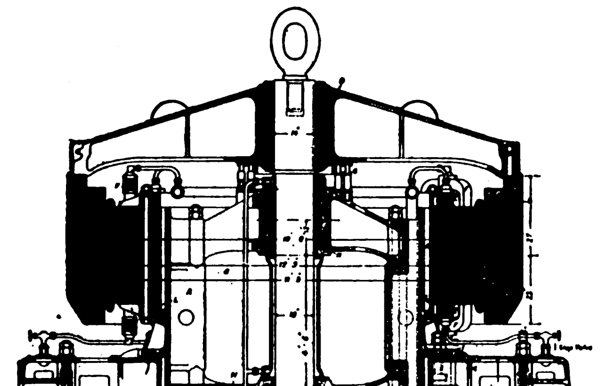

FIG. 1.

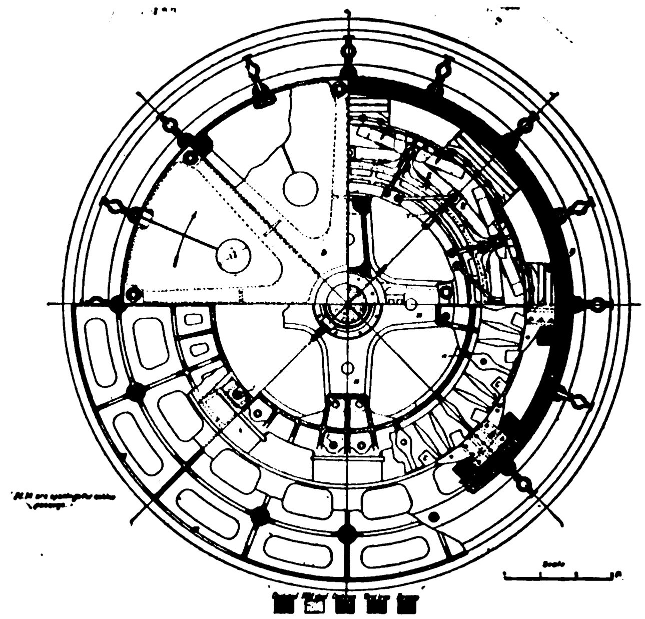

FIG. 2.

There are 16 armature coils, eight being of one kind, called "short" coils, and eight of another kind, called "long" coils, the length of wire on each coil being the same. The short coils are bent over on the top and bottom end plates, and the long coils are wound in one plane and enclose the short coils. This is clearly shown in the drawings, where the "short" coils are marked E and the "long" F. I find that if we are to have a very stiff field, with first-class quality of iron in the fields, each coil would consist of 72 turns of pure copper wire, No. 0 of the Brown & Sharpe gauge, which gives a very low density of current and reduces the heat.

---

[1] See THE ELECTRICAL ENGINEER, Dec. 20, 1893, to Jan. 10, 1894, inclusive.

ing. In fact, it has been my view that, in designing the machines for so great and permanent a work, every effort should be made to reduce the rise in temperature, even to far below what has ever been done in the past. The unequal expansions and contractions of materials in a machine of this kind are very injurious to its permanence, and affect the insulating material seriously. The layers of wire in the coils are separated by mica. Each coil when wound has strips of insulating material laid spirally round it so that oil may circulate freely in the intervals, and the whole is encased in a casing of strong insulating material. The material which I prefer for this purpose is certainly Woodite, an eighth of inch of which will not break down with 30,000 volts, and which is not acted upon by oil even at high temperatures. I have a record of tests with oil which are conclusive on this point. It is quite the best material I have seen for the purpose, though costly, and being a secret process, it may be difficult to ensure uniformity.

The frames of the bearings are of cast iron, with four radial arms, which rest upon four projections cast on the vertical cylinder, and are bolted to them, as already stated. By this means, when the field magnet with the shaft has been lifted out of place, the bearings can be twisted through an angle of 45 degrees in a horizontal plane and then raised out of place, leaving a space 5 feet in diameter through which portions of the turbine shaft can be raised for repair. The bearings are oiled at the centre by oil forced under pressure through a pipe. The oil is then distributed over the bearings by spiral grooves. A spiral groove is also cut in the hub of the frame, with a pipe at each end to admit of water circulation to cool the bushing. At two opposite sides of each bearing the bushing is made thin, and a rod of bismuth is soldered thereto; so that if the bushing is heated a thermo-electric current shall be created which, by means of a relay, can ring a bell in the power house. When this occurs, water can be immediately admitted to cool the bearings, and the attention of the workmen is drawn to the necessity of an examination.

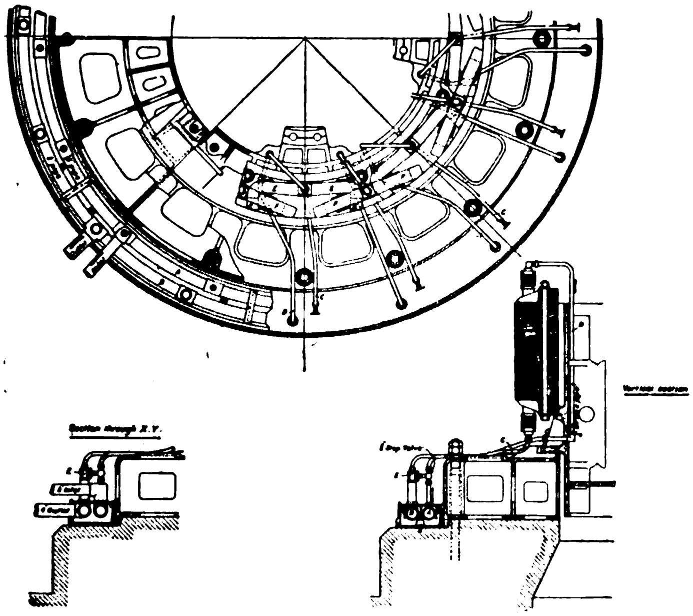

FIG. 3.

One of the parts which required most consideration was the material of which the spider supporting the field magnets should be constructed. The best plan is to make it of steel (although, as pointed out before, it is shown in the drawings as a bronze casting), for the sake of lightness, and to cover it with a copper covering, which might, I think, be spun; or, perhaps better, electro-deposited nickel might be used. Between the pole-pieces the space is filled up with a screen or plate of metal so as to direct the air ventilation only upon the parts which most require cooling.

COLLEGE NOTES.

COLUMBIA COLLEGE UNIVERSITY EXTENSION LECTURES.

A class in mathematics is about to be formed for the New York Electrical Workers. Mr. Max Osterberg who has laid out a plan of instruction will be in charge of the course. He intends to introduce the subject commencing with arithmetic and gradually lead up to algebra and geometry, giving as much as is necessary for an electrical worker to know, in order that he may deal intelligently with the problems that present themselves to him almost daily in connection with wiring, and other electrical work.

The formation of this class is due to the desire of many attending the course of lectures on practical electricity, delivered at Cooper Union, to become better acquainted with the phenomena of electrical science.

ELECTRICAL WORK AT COLUMBIA.

Although it is but comparatively recently that Columbia College has actively taken up instruction in electrical engineering the work it has already accomplished easily places it abreast of our best schools devoted to this branch. Columbia is, moreover, not confining its work and influence to the class room but is extending it far beyond as, for instance, by its admirable course of University Extension Lectures given in connection with the Cooper Union in which some of the foremost electricians in the country are taking part. In addition to this, a course of five lecturers on Electricity is being given at Yonkers.

The fourth course of lectures in New York will be devoted to "Electricity as a Factor in Modern Life," and will be given by Prof. Francis B. Crocker. The dates and titles of these lectures are as follows: March 6—The Dynamo and Electric Lighting. March 13—The Electric Motor and Transmission of Power. March 20—The Electric Railway. March 27—The Telegraph and Telephone.

The lectures which will be held at Cooper Union will be fully illustrated by experiments. No tickets of admission will be required and the doors will be closed promptly at 8 o'clock.

SOCIETY AND CLUB NOTES.

NEW YORK ELECTRICAL SOCIETY.—"THE ELECTRIC LIGHTING OF THE WORLD'S FAIR."

A lecture on the above subject will be delivered by Mr. Thomas Commerford Martin, at Columbia College, on Thusday, March 15, at 8 p. m., before the New York Electrical Society. The lecture will be profusely illustrated by lantern. In the collection of data and slides, Mr. Martin has had the active assistance of Mr. Luther Stieringer, who was the consulting electrical enginer of the Fair. Special attention will be given to night views of the Fair, exhibiting a wonderful advance in the photography of scenery and scenic effects after dark, and exemplifying the beauty of the electric light for spectacular purposes. Among the many points of interest to be treated in this original manner will be: The Electricity Building; The Tower of Light; Scenic Theatre; The Dome of the Horticultural Building; The Lagoons; Manufactures Building; The Big Search Light; The Fine Arts Building; Administration Building; The Grand Court of Honor; The Stieringer Electric Fountains; Effects Produced by Electric Illuminations, etc., etc. The scenes will be shown in contrast of daylight and night effect. Ladies are invited to this meeting of the Society.

LITERATURE.

The Practical Management of Dynamos and Motors. By Prof. F. B. Crocker and Dr. S. S. Wheeler with a chapter by H. A. Foster. Second Edition Revised and enlarged. *D. Van Nostrand Co.* Cloth 8vo. 205 pages, 99 cuts. Price $1.

In bringing out the second edition of their useful little treatise, Messrs. Crocker and Wheeler, with the help of Messrs. Dunn and Foster, have placed the profession under a real obligation. The book is now twice as large as before, and we are almost sorry it is not four times the size. Every page is freighted richly with valuable data, information, instruction and advice. The minutiæ is simply wonderful, and yet in breadth of treatment the book as a whole is hard to surpass. It its true that the work deals essentially with management, but by the time the reader has studied and mastered these pages, he ought to know as much about the machinery as its builders. Little remarks dropped quietly and casually here and there, open up wide, long vistas of thought, and explain many obscure points in construction; and one feels throughout the influence of very shrewd and observant minds. It is fortunate that the publishers issue the book in such compact form. It goes in the pocket and should always be there ready for consultation. We can only hope that every one of our readers will provide himself with a copy.

MR. H. DEARBORN GARDINER is well known in electrical circles by his clever pen-and-ink work illustrating articles that have appeared in THE ELECTRICAL ENGINEER, *Scribner's Magazine, Harper's Weekly*, etc. He has now placed on exhibition at the gallery of Sanchez & Co. 126 West 23rd street, New York City, from March 12 to March 22, a collection of seventy water color and black and white drawings of Spanish subjects. Mr. Gardiner has spent several years in Spain as art student and working artist, and these fruits of his work there form a delightful exposition of his skill.

A BIG OPENING FOR SMALL ARCS.

THOSE who follow carefully the signs of the times cannot fail to have noted unmistakable indications of an increased activity in the demand for arc lighting. Being the first form of illumination to arrive at a practical commercial stage it naturally received the undivided attention of inventors for several years before the incandescent light was reduced to practice, but since the advent of the latter it has been allowed to remain practically at a standstill. It had to give way before the mellow incandescent lamp, owing to the great facility of subdivision into units which could be placed exactly where wanted. The enormous importance of this ease of subdivision can be no better brought home to economists than by adverting to the well known fact that for the same amount of electrical energy expended the arc lamp produces 10 times as much illumination as the incandescent lamp, and yet the incandescent lamp has triumphed. With this condition of affairs confronting us it requires no great amount of discernment to predict that the next step towards improvement in arc lighting must be in the direction of arcs of small power, say from 50 c. p. up. We are aware that attempts at lamps of this character intended for general interior illumination have been made, more especially abroad, but even there their success has been very limited. Considering the perfection to which arc lamps have been brought at the present time, there seems to be but one thing which has up to the present militated against the use of such small power arcs, and that is the frequent necessity for renewing the carbons, not to speak of the cost of such renewal. The latter, however, in domestic installation, must be considered a matter of even less importance than the trouble of renewal.

If the view we have taken is correct then the public ought not to be allowed to wait long for the small arc. We base our hope in this matter on the results obtained with the Howard arc enclosing cylinder. Whatever may be the criticisms raised against this system as applied to lamps suspended out of doors they must of necessity fall to the ground when applied to lamps intended for in-door use. A close study of the situation forces the belief upon us that a thoroughly practical arc lamp of 100 candle power or thereabouts has a field before it as extensive as that of the incandescent lamp itself, and, indeed, it would not be difficult to predict its effect upon incandescent lighting as an industry The introduction of such a lamp however, need by no means create a panic in incandescent light circles. If we construe rightly the opinions expressed by the most advanced station managers, and confirmed by a number of those who took part in the discussions at the recent N. E. L. A. Convention in Washington, these managers have rightly begun to look upon their plants as electrical *power* generators as distinguished from *lighting* centres. Any method, therefore, which would enable the customer to obtain the most light for a given amount of money is the thing which the station manager will find to be the most profitable in the long run. Like the experience gone through by many upon the introduction of meters, the general introduction of arc lamps on incandescent circuits might be found to cut down the station output temporarily, but the revenue would be found to have increased. It is evident, therefore, that with the advantage on the side both of the customer and of the central station, nothing ought to stand in the way of the small arc. What can be done in the way of arc lighting on constant potential circuits is well shown in the 2,700 lamps now burning in Brooklyn, according to Mr. Barstow's report, with 400 more waiting to get on the circuit. From what has been said above it might be inferred by some that the days of the incandescent lamp are numbered, but such a conclusion would be, to say the least, very erroneous. The field is large enough for both and we have wished merely to point out a means of enlarging still further the scope of electric illumination. With that scope enlarged, the incandescent will be in greater demand than ever, but it will be reinforced and assisted by the small arc.

GROWTH OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

The representative character of such a body as the National Electric Light Association must be largely due, in the long run, to the support that it derives from the operating local companies. After such a successful and altogether delightful convention as that at Washington, no one will deny that the Association has already great strength and influence. In a manner not altogether uncommon, it has drawn sustenance from its troubles, and surviving a long series of conflicts and difficulties is to-day respected and valued throughout the country. Because of its work and its aims for the future, we think that local companies out of membership are not doing their duty to themselves or their fellows, and are debarring themselves from many opportunities of co-operation and usefulness.

As a matter of fact, the numerical strength of the Association is far below what it should be. Assuming as we may from the returns, that it embraces not less than 150 local companies in good standing, and that there are over 2,000 local electric light companies in the country, it will be seen that only about 7 per cent. of such companies are in membership. But the percentage should be much larger than that. The percentage of capitalization would probably come out far higher, but what is needed is the active participation of the medium sized companies, which have as a matter of course to be handled by a comparatively small executive staff and which can therefore best furnish and exchange valuable experience or data. It would, we think, be a good thing if Secretary Porter could devote a portion of each year to personal canvas of companies not in membership. It is our conviction that the results of such a campaign would be very gratifying.

We may mention as an item of information that the American Water Works Association has a membership of about 12½ per cent. of the possible, representing one-half of the invested capital. The American Street Railway Association has a membership of about 25 per cent., representing two-thirds of the invested capital. The latter instance is the more striking and encouraging of the two, and it is noteworthy that its membership is in no small degree electrical. An interesting feature of the recent Washington convention was the appearance of several visitors connected with electric street railway companies. The number is likely to grow, as the two interests of lighting and traction have many similar features already and are bound to have more. President Francisco who is of an eminently practical turn of mind, and fully alive to dangers that others have not seen so quickly, will, we venture to hope and believe, employ his term of office in rallying to the Association large numbers of the local companies to promote whose welfare it was established and for whom it may at no distant date have to perform vitally important service.

SHOULD ELECTRIC RAILWAYS SUPPLY POWER TO INDIVIDUALS?

In commenting last week on the work accomplished at the Washington Convention of the N. E. L. A., and referring to the new safe wiring rules adopted, by the Association, and their effect on future work of that character, we expressed approval of the rule prohibiting the introduction of railway circuits into buildings for power distribution purposes. Apropos of this, a correspondent writes to inquire why it is not just as fair for the railway company to sell power for light as for the electric light company to sell power to the electric railway company to operate its cars. Taking up the question of safety, first, we would reply that it must be apparent that to introduce a 500 volt ground return circuit into any building is inviting disaster and should be strenuously opposed by all having the true interests of the electrical industry at heart. While the question of personal safety does not enter here as a predominant factor, a shock from a 500 volt circuit is anything but pleasant, and with a grounded circuit the chances of attendants obtaining such amount to certainty. Looked at from the side of the danger from fire due to leaks from the circuits, there can be no two opinions as to the advisability of excluding such circuits from buildings. Even with a complete metallic circuit, we consider 500 volts direct current as too high for general indoor distribution, and hence we can find no reason for modifying our opinion on this matter. As regards the strictly ethical side of the question, there is of course no good reason why a railway company should not supply current for general power distribution, but where such work is contemplated, the power service to customers should be kept entirely distinct from that of the railway, so far at least as the electrical equipment is concerned. No better example of such combination stations could probably be found than that at Milwaukee which we describe in this issue, in which the feature of absolute separation of service is strictly adhered to.

A MODEL CENTRAL STATION.

In this issue we begin an exhaustive description of one of the best designed electric lighting and power plants which have thus far been erected in this country. The plant at Milwaukee may be looked upon as one of the forerunners of a class which is gradually finding general acceptance among electrical engineers and which presents a good object lesson in economical operation of lighting and power stations under one roof and one management. The station which Mr. Otto Frick describes is largely the design of Mr. J. C. Henderson and does credit both to him and to those who furnished the means to carry out his ideas. We shall be glad to have any of our readers who are interested offer their comments on any feature they may deem a fit subject for criticism.

MISCELLANEOUS.

POLYPHASE TRANSMISSION.[1]—I.

BY CHARLES F. SCOTT.

ALTERNATING CURRENT PROBLEMS.

WHEN alternating current was introduced for lighting it presented many new problems to the electrical engineer. Numerous difficulties and dangers were predicted by the theorist, but in ordinary service most of these have fortunately lain dormant. These difficulties are apt to appear, however, when alternating current work is attempted on a large scale. The introduction of large units, heavier currents, higher potentials or power service are apt to increase the effects of self-induction and capacity so that they will now demand careful consideration. The impetus which electrical engineering is receiving from the introduction of the polyphase system, which brings with it large units and long distances, naturally directs attention to the general problem of alternating current transmission and distribution.

A complete and exhaustive solution of this problem is by no means a simple one and the attempted solutions generally lead to formulæ and diagrams which are possibly even more perplexing than the phenomena. If even the electrician, who devotes all his energy to new problems, can scarcely keep abreast of the times, it is not surprising that the practical engineer and station manager become perplexed and confounded at the apparently erratic phenomena observed in practice or described in print. Theoretical articles appear on variation in wave form, harmonics, so-called Ferranti effects, increased resistance in conductors with alternating currents, hysteresis, peculiar magnetic currents, resonance, oscillations, lag, capacity, self-induction. Many of these articles, although evidently intended to be of service in engineering, show apparently no adequate appreciation of the practical bearing and relation of the subjects treated. Consequently the average engineer becomes bewildered and perplexed, and concludes that theoretical explanations are of little value to the practical man. There are, however, many points of great practical importance which admit of fairly simple statement and explanation. The particular element to be considered in the present paper is the transmission circuit.

EXPERIMENTS ILLUSTRATING SELF-INDUCTION.

One of the fundamental characteristics of alternating current working is self-induction. The effect of self-induction is most readily shown by a simple experiment. A wire having a resistance of 10 ohms may be wound in a coil. Ten volts will send a continuous current of one ampere through this coil. An alternating current of a certain frequency will require 50 volts for producing one ampere through the same wire (Fig. 1*a*.) In the diagrams the numbers above the circuit are for continuous current and those below are for alternating current. If a one ampere, 50 volt lamp be placed in series with the coil and a current of one ampere be passed through the two in series, the E. M. F. required for continuous current is 10 volts on the coil and 50 volts on the lamp, or 60 volts across the circuit, and the E. M. F. required for alternating current is 50 volts across the coil and 50 volts across the lamp, which gives, not 100 volts, but 78 volts measured across the two in series (Fig. 2). If two lamps be placed in multiple and connected in series with the coil, two amperes will require for continuous current 20 volts on the coil and 50 volts on the lamps, or 70 volts across the circuit. For alternating current, the E. M. F. on the coil is 100 volts and on the lamps 50 volts, and on the circuit across the two in series the E. M. F. is 120 volts (Fig. 3)

The two lamps which are in multiple may be placed in series with a second coil so proportioned that an E. M. F. of 50 volts will send one ampere alternating current through the combination, and a continuous current of one ampere would be caused by 35 volts. This combination may be treated as a unit and may be used to replace the single lamp in the above test. (Fig. 2.) If this combination be placed in series with the first coil, the E. M. F. required for sending the continuous current through the circuit will be 10 volts on the coil and 45 volts on the circuit. If the alternating current of 1 ampere be sent through the circuit, 50 volts will be required across the combination and 50 volts across the coil, the same as with the single lamp, but the E. M. F. across the circuit is no longer 78 volts, but has increased to 95 volts (Fig. 4).

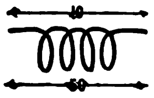

FIG. 1*a*.

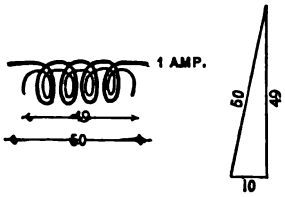

FIG. 1*b*.

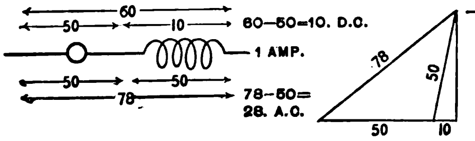

FIG. 2.

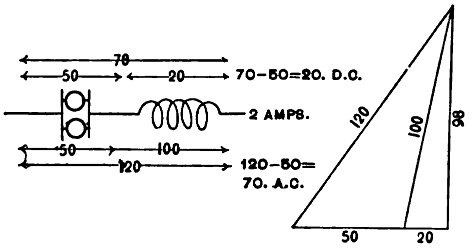

FIG. 3.

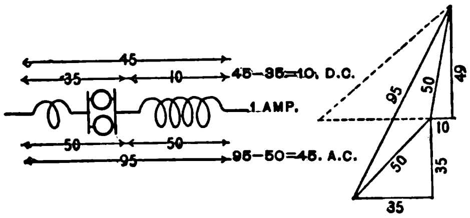

FIG. 4.

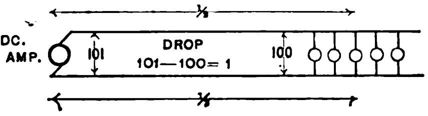

FIG. 5.

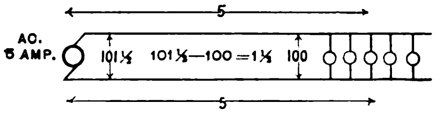

FIG. 6.

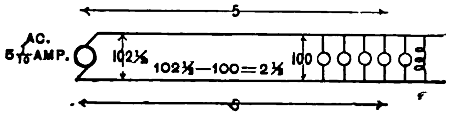

FIG. 7.

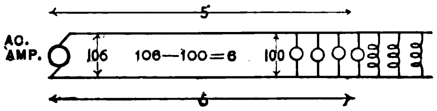

FIG. 8.

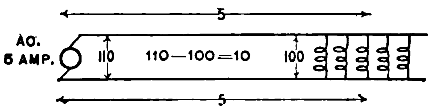

FIG. 9.

The important facts to be noted in these experiments are; (1) that the sum of the alternating E. M. F.'s on the elements in series is greater than that required on the terminals; (2) that the alternating E. M. F. for supplying the lamps in series with a coil is greater than the continuous E. M. F., and (3) that the difference between the two becomes greater as the number of lamps is increased (Figs. 2 and 3). It is also to be noted (4) that if the same alternating current be supplied through a coil, first to a lamp alone and then to a combination including lamps and a coil, a higher E. M. F. is required when the combination is used (Figs. 2 and 4).

These relations, which seem rather perplexing, may be illustrated in a very simple way by diagrams. In the case of the coil alone, in which 50 volts are required for producing one ampere alternating current and 10 volts for one ampere continuous current, these two E. M. F.'s may be represented by the hypothenuse and one side of the familiar right angle triangle. The remaining side represents the counter E. M. F. in the coil. If a second wire had been wound on this coil in parallel with the first it would be found that when one ampere is passing there is an E. M. F. on the terminals of the second, or idle, wire of 40 volts (Fig. 1*b*). This is caused by the field produced by the alternating current. An equal E. M. F. is of course induced in the wire carrying the current, as the two wires occupy virtually the same position. This counter E. M. F. is seen to correspond with the third side of the triangle. Suitable measurements would show that this counter E. M. F. occurs later than the current through the coil and that its maximum value occurs when the current is passing through its zero. This relation is shown in the diagram by the 90 degree relation of the lines representing counter E. M. F. and the volts required for sending continuous current through the line.

SELF INDUCTION IN CIRCUITS.

An ordinary circuit may be considered as a choke coil in which there is a single turn. The action in this case is very similar to that illustrated above with a coil of many turns. The effect of self-induction in a circuit may be most readily understood by some simple diagrams. A current of say 5 amperes is delivered at 100 volts over a circuit of ⅕ of an ohm resistance. The self-induction of the circuit is such that 5 amperes generates a counter E. M. F. of 10 volts. Both continuous and alternating currents are used and the generator E. M. F. is in each case adjusted to give 100 volts at the load.

The load consists first of five incandescent lamps. A coil of high self-induction is then added, which increases the current from 5 to 5.1 amperes. One of the lamps is then cut out and replaced by coils of such a self-induction as to give a total of 5 amperes. Then all of the lamps are cut out and coils substituted of such a number as to take 5 amperes at 100 volts. The E. M. F. required on the generator and the resulting drop, or difference of E. M. F. at the dynamo and at the load are given in the diagrams and in the following table:

	Continuous Current.	Alternating Current.			
	Fig. 5.	Fig. 6.	Fig. 7.	Fig. 8.	Fig. 9.
Current in line	5	5	5.1	5	5
" " lamps	5	5	5	4	0
" " coils	0	0	1	3	5
E. M. F. on load	100	100	100	100	100
" " line	1	10	10	10	10
" " generator	101	101.5	102.5	106	110
Drop—total	1	1.5	2.5	6	10

It is to be noted that with exactly the same circuit for supplying five lamps with the same amperes at the same E. M. F., there is an increase of drop between generator and load when continuous current is replaced by alternating current. This drop is much less than the volts required for sending the alternating current through the line, and it moreover increases enormously as the load becomes even slightly inductive. Thus when the current is increased only two per cent. (from 5 to 5.1 amperes, Figs. 6 and 7) by the addition of inductive load to the lamp load, the increase of drop due to self-induction is increased from ½ per cent. to 1½ per cent. or a threefold increase. When the load consists of four lamps and coils are added in multiple to take a total of 5 amperes, or the same as that taken by the five lamps from the generator, the drop is four times the drop when five lamps alone are in circuit; Fig. 8. If the remaining four lamps be replaced by coils, Fig. 9, the drop increases from 6 to only 10 per cent. The effect therefore of a slight self-induction in the load causes a much greater proportional drop than the presence of a large self-induction. A counter E. M. F. of 10 per cent. is not at all likely to occur in a 100 volt line carrying a small current. The figures given, however, serve as an illustration of the percentage variations which are liable to occur in other parts of the system.

DROP IN CONTINUOUS AND ALTERNATING CIRCUITS.

The word "drop" in continuous current calculations has a perfectly well defined meaning. In the case of the five lamps which take 5 amperes at 100 volts through a circuit of one-fifth of an ohm, as illustrated in Fig. 5, the drop is (1), the difference between the E. M. F. at the generator and at the lamps, or (1) volt, which is one per cent; (2) it is the E. M. F. required for sending the current through the line. This is equal to the current multiplied by the resistance, and is the E. M. F. which would be required for sending the current through the line if the load were short circuited; (3) a drop of one per cent. means also that the energy lost in the line is one per cent. of that delivered by the generator; (4) a loss of one per cent. in the line also signifies that the energy delivered is one per cent. less than that supplied by the generator.

In alternating current work the same uniformity does not exist; for example, in the experiments with the same five lamps and the same line, (1) the generator pressure was 101½ volts, or ½ per cent higher than that of the lamps; (2) the E. M. F. required for sending a current through a line short circuited is 10 volts, or 10 per cent.; (3) the energy lost in the wires is C^2 R, or five watts, which is one per cent. of the energy when five lamps are supplied. If four lamps and low resistance coils are connected to the circuit, the energy delivered is, say, 400 watts and the loss is 1¼ per cent.; (4) if the coils alone are supplied and their combined resistance is equal to that of the circuit, or one-fifth of an ohm, then the losses in load and line are equal, and the actual line loss is 50 per cent. The apparent energy at the generator is 550 watts (110 volts and 5 amperes) and the apparent energy delivered is 500 watts (100 volts and 5 amperes) so that the apparent line loss is 9 per cent.

It is therefore evident that the several elements commonly referred to as drop or per cent. loss with continuous current are so modified when alternating current is used that it is possible for no two of them to have the same value. Moreover, with alternating current none of these elements may have the same per cent. value as that for continuous current on the same circuit (Figs. 10 and 11.)

LOSS AND REGULATION.

The two vital factors in the line are loss and regulation. The losses are C^2 R and should be expressed in watts or horse power, or as a per cent. of the energy delivered to the line. The practical point in regulation is the difference in E. M. F. at the generator and at the load. When these two factors are known it is generally immaterial what E. M. F. might be required for sending current through a short circuited line. The word "drop" is applied to the difference in E. M. F. between the generator and the load. The regulation is generally expressed in per cent. of generator E. M. F. but in this paper the E. M. F. at the load will be considered 100 per cent., as this is the element to be kept constant, while the E. M. F. of the generator is variable, depending upon the load and other elements. The regulation, or drop, in the alternating current circuit is dependent largely upon the counter E. M. F. of the line. The factors which practically determine the counter E. M. F. of the line are size of wire, distance between wires, length of circuits, frequency and current. Mr. A. E. Kennelly has given very complete curves[2] for determining the impedance of pole lines. The impedance factors given may be used for finding the current through a given line which is short circuited at one end, when the E. M. F. and frequency are known. The impedance factor of the line for supplying five lamps described above is 10, as the alternating E. M. F. is ten times the continuous E. M. F. for the same current when the line is short circuited. The word "drop" is applied in Mr. Kennelly's article to the volts required for overcoming impedance in a circuit, and the impression that this is the same as the drop in continuous current circuits was not corrected in the paper, nor was this most practical point raised in the discussion. The relation between impedance and loss was, however, demonstrated mathematically in a communication after the meeting. The figures given in connection with the foregoing diagrams show very clearly that a circuit having the same impedance may have a drop between the generator and the load of from 1½ to 10 per cent., depending upon the character of the load. Impedance therefore does not determine regulation.

CALCULATION OF DROP IN ALTERNATING CIRCUITS.

The regulation of a circuit is in general determined by two elements; the counter E. M. F. of the circuit and the self-induction of the load. The counter E. M. F. of a line depends upon the size of wire and the distance between wires, and increases directly as the length of the circuit, the current and the alternations. The counter E. M. F. of a line has been calculated for a number of cases which are likely to occur in practice and the results are given in Fig. 2. The drop, or difference of potential between generator terminals and the load terminals due to the counter E. M. F. of the line depends, as has been shown, upon the self-induction of the load. The latter is best expressed by a power factor or a factor by which the product of the amperes and volts giving the apparent energy must be multiplied to give the true power in watts. The power factor for incandescent lamps is 1.00, or the apparent energy is equal to the true energy. The power factor for converters loaded with incandescent lamps is usually over .99. The factor for unloaded converters varies from .50 to .80 and in open magnetic circuit converters, notably the "hedgehog," the factor may be as low as .05. The drop due to self-induction on the line (which, plus the ohmic drop, will give approximately the total drop) corresponding to various power factors of the load is given in Figs. 12a and 12b. The curves show that if the power factor be 100 per cent., as it is with incandescent lamps, the inductive drops for various counter or inductive E. M. F.'s are .02 per cent for 2 per cent.; .08 per cent. for 4 per cent.; .18 per cent. for 6 per cent.; .32 per cent. for 8 per cent.; .5 per cent. for 10 per cent.; 1.2 per cent. for 15 per cent.; and 2.0 per cent. for 30 per cent. The curves show that the drop increases very rapidly at first if the power factor becomes less.

These relations may be elegantly determined by a simple diagram on section paper ruled in tenths. Draw an arc through a quadrant with a radius of 100. At a distance from the centre on the horizontal, equal to the power factor of the load, erect a perpendicular and extend it to the arc. This line represents the counter E. M. F. of its load and its value read directly on the scale gives the counter E. M. F. in per cent. of the E. M. F. upon the load. From the intersection of the arc draw a horizontal line outside the circle equal on the scale divisions to the per cent. in terms of the E. M. F. on the load which would be required for sending the normal amperes continuous current through the line resistance. From the end of this horizontal line draw an upward vertical equal to the counter E. M. F. of the line expressed in per cent. of the E. M. F. on the load. A line from the centre to the upper end of this vertical represents in direction and magnitude the E. M. F.

---

[2] *Transactions* American Institute of Electrical Engineers, April, 1893.

which must be impressed on the circuit. If from the same centre an arc be drawn through this point to the base, the scale divisions on the base between the two arcs measures the total drop caused by the lines in terms of the E. M. F. on the load. (Fig. 10.)

SELF-INDUCTION IN TRANSFORMERS, ETC.

Self-induction exists in line, generators, transformers, secondary wiring, and sometimes in the load. In each case the effect of the self-induction upon regulation depends largely upon the self-induction of the total load which it supplies. Thus, the regulation of a generator depends upon the total self-induction of the line, transformers and load. Again, the regulation of a line supplying converters depends both upon the self-induction of the converters as well as that of the useful load. The same analysis, diagrams and tables which have been used above in connection with the line will apply to the transformers and approximately to the regulation of the generator.

An ordinary transformer has a primary self-induction, a secondary self-induction and a mutual induction, which becomes a ready source of a very complicated and perplexing analysis when the complete action is described in theoretical terms. Practically, however, the action of the self-induction in the transformer may be expressed in a very simple way, and it is readily seen that this self-induction has a very important bearing upon the regulation of the transformer. The regulation of the transformer is very similar to that of a line, as explained above. If the secondary coil be short-circuited the E. M. F. on the primary may be adjusted so that the normal full load current passes through the apparatus. This E. M. F. corresponds very closely to the E. M. F. required for sending current through a short circuited line and in ordinary transformers is practically equal to the counter E. M. F. and may be considered equal to it.

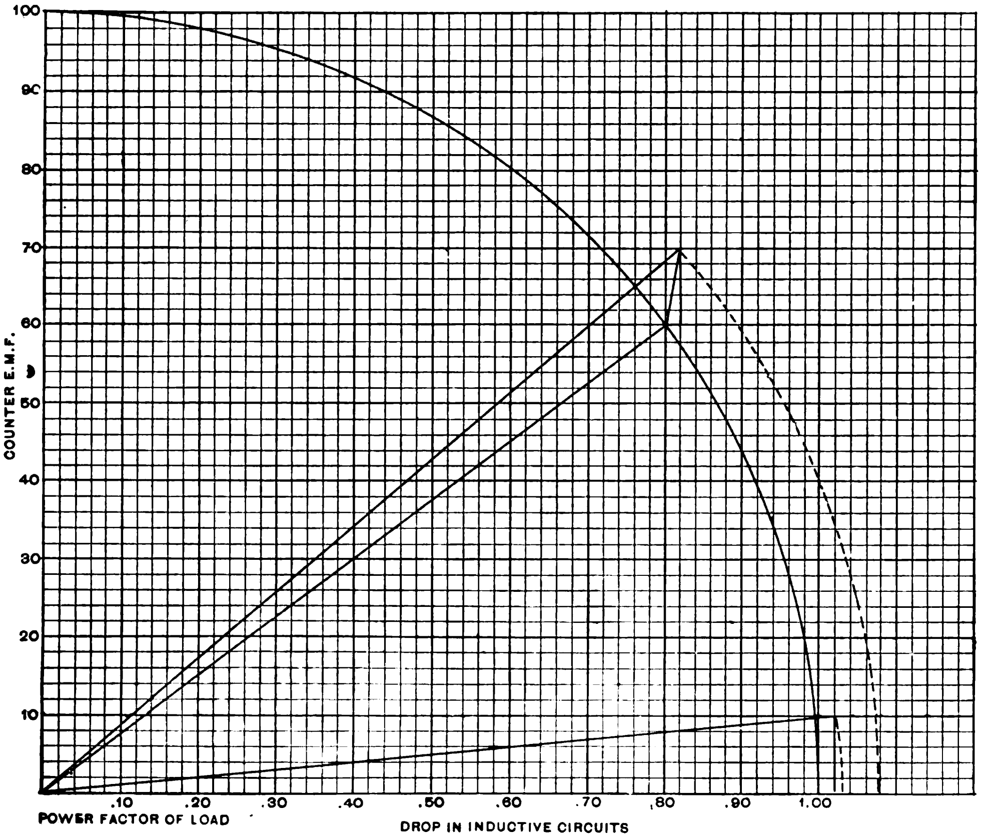

FIG. 10.

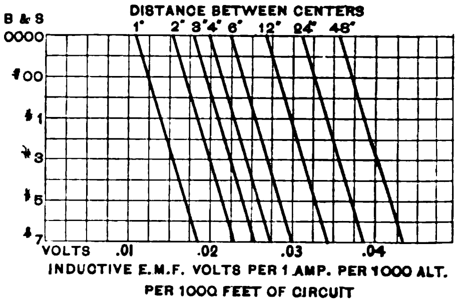

FIG. 11.

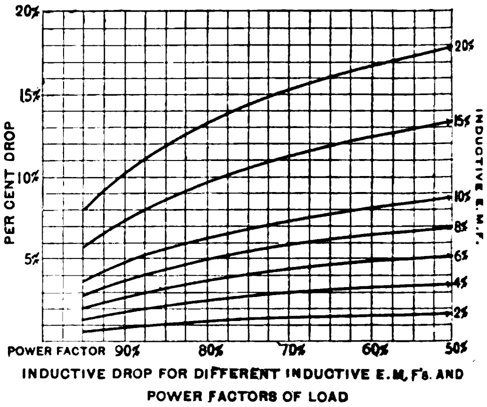

FIG. 12*a*.

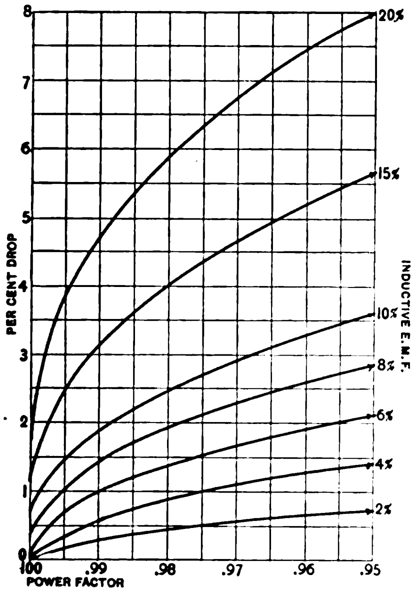
A transformer may be taken for experiment in which the E. M. F.'s are 1,000 volts and 100 volts. If 5 volts, or ½ per cent. is required for sending through the primary a continuous current equal to the normal full load current of the transformer, and if a similar E. M. F. in the secondary is ½ volt, or ½ per cent. then the ohmic loss to the transformer is one per cent. and the drop in pressure at the secondary terminals between no load and full load will be one per cent. of the self-induction be negligible. If, however, there is a self-induction so that 100 volts, or 10 per cent. is required for sending the normal current through the primary when the secondary is short circuited, then the drop in pressure is in general greater than one per cent. depending principally upon the character of the load. The load may be non-inductive, as lamps, or it may be more or less inductive. The experiments described above, in which a line had the same per cent. ohmic and inductive characteristics as the converter just described apply to the converter as well as to the line. The drop on such a converter therefore may vary from 1½ to 10 per cent. when delivering its rated current. Arc lamps or fan motors will produce a very much greater drop than incandescent lamps. The power factor of an alternating current arc lamp varies considerably, but in a number of cases has been found between 85 and 90 per cent. The drop when incandescent lamps are replaced by arc lamps on the transformer just described increases from about 1½ to 5 or 6 per cent.

A secondary line, if it carry a large current, may have a counter E. M. F. of several volts. This may not be enough to increase appreciably the drop in the line between the transformer terminals and incandescent lamps. The transformer, however, delivers current to the secondary circuit and to the lamps, so that the regulation of the transformer may be affected by the self-induction of the secondary circuit. Cases have occurred in which transformers of a very old type possessing high self-induction were supplying very large secondary currents and the resulting drop in the transformers was increased several per cent. For example, a circuit of No. 0000 B. & S. wire supplying 100 amperes to 50 volt lamps at a distance of 100 feet has an ohmic drop of 2 per cent. The constant for counter E. M. F. of this circuit, if the wires be 6 inches apart, is .022. The volts at 16,000 alternations are .022 × 100 × .1 × 16 = 3.52, or 7 per cent. of 50 volts. The inductive drop in the line corresponding to 7 per cent. is .25 per cent. The power factor of the aggregate service of the transformer is the second side of a right angle triangle of which 7 is one side and 100 is the hypothenuse. This is 99.7, which is the power factor of the total load on the transformer. If the self-induction of the converter be 10 per cent., the inductive drop is 1.2 per cent.; if 20 per cent. the inductive drop is 3.4 per cent. and if 80 per cent, the inductive drop is 7 per cent. The aggregate drop in the converter and secondary circuit in the latter case would be, say, 2 per cent. for ohmic drop in transformer, 2 per cent. ohmic drop in line, 7 per cent. inductive drop in transformer and .25 per cent. inductive drop in line, or a total of 11.25 per cent. The necessary ohmic drop is 4 per cent. and the inductive drop resulting from self-induction in traneformer and line is therefore 7.25 per cent. If the number of alternations be reduced to 7,200 the inductive drop would be reduced from 7.25 per cent. to 1½ per cent.

ORDINARY TESTS UPON TRANSFORMERS.

The practical bearing of the self-induction of a transformer upon its regulation and the exact relation between the two does not seem to be clearly recognized, and even Dr. Hopkinson and Dr. Fleming, who have made very exhaustive tests upon transformers, comparing different methods of testing and different types of transformers, have not brought out this point. Attention is given to the exact form of the current wave, and measurements upon the iron losses are attempted within very close limits of error. Their measurements upon the regulation of the same transformer, however, vary from 2 per cent. to 2.4 per cent. or one measurement is one-fifth greater than the other. The presence of a light induction in the secondary load would have caused a very considerable increase, and it is probable that the difference in the measurements made were due to difference in the self-induction in the instruments used or in the load at the time the tests were made. No note is made of the effect of the self-induction of the load upon regulation, although regulation is one of the most vital points in the practical use of transformers Even the temperature at which the drop was measured is not stated, although the resistance of a transformer when continuously working may be 20 per cent. greater then when cold. The elements of practical importance in a transformer are (1) the iron loss, in respect to the efficiency; (2) in the regulation, in respect to the satisfaction of service, and (3) the temperature to which the insulation is subjected, as affecting the life of the transformer. In the ordinary tests by theoretical men, the iron loss is measured to a very high degree of refinement, although the iron loss in transformers is the one thing which cannot be controlled, and is certain to vary 10 to 15 per cent. in commercial manufacture of transformers of the same size. The wave form of E. M. F. on different dynamos or the difference in form under different conditions of load on a circuit may make the loss under different commercial conditions vary several per cent. This renders more refined measurements of no practical use unless the conditions are stated. The temperature of the iron also affects the loss. The full load efficiency is usually given as if it had a great deal of importance, whereas the losses in copper during 24 hours ordinarily amount to but a trifling per cent. of the total losses. The regulation, and the temperature to which the insulation is subjected and which it is able to stand are generally not mentioned in reports of tests. The usual investigations and the papers published on the alternating current transformer may perhaps accurately express many facts in complicated formulæ, but the practical bearing of these points in every-day working seems to be totally ignored.



INDUCTIVE DROP FOR DIFFERENT INDUCTIVE E.M.F's. AND POWER FACTORS OF LOAD

FIG. 12b.

Lighting the West Side Tunnels.—The direct coupled Waddell-Entz generators on McEwen engines and a portion of the fifty Nutting arc lamps ordered some time ago for lighting the new tunnel of the West Chicago Street Railway, have been started and are now in daily operation furnishing light for laying the cable tracks through the tunnel. The arc lamps are run two in series from the 110 volt constant potential circuit. This tunnel is said to be the second largest in size in the world, as regards diameter. The entire plant is expected to be in operation within a month, and as the conditions under which the apparatus has to operate, will be unusually severe, the performance of the plant will be watched with much interest by all electrical engineers as well as others interested.

LEGAL NOTES.

NO TERRITORIAL RESTRICTION ON EDISON LAMPS RIGHTFULLY ACQUIRED.—EDISON ELECTRIC LIGHT CO. vs. ROBERT STAFFORD et al (THE IMPERIAL HOTEL, NEW YORK).

Last year the General Electric Co., secured a decree enjoining the proprietors of the Imperial Hotel in New York from using other than Edison lamps. The proprietors of the hotel thereupon obtained Edison lamps, but not from the New York Edison Electric Illuminating Co., the Edison licensee for New York City below 70th street. The General Electric Co., then moved to punish the proprietors of the Imperial Hotel for contempt. Judge Lacomb of the U. S. Circuit Court has just handed down a second memorandum denying the motion, and holding that the Imperial Hotel had the right to procure Edison lamps from any source it desired. We give the text of the memorandum below:

Lacombe, C. J.:—The additional affidavits show that the lamps of the Edison pattern used by defendants have been obtained by them by purchase from three sources. 1. McLeod, Ward & Co. dealers in electrical supplies in the City. 2. The Jaynes Electric Co., a copartnership in Buffalo dealing in such supplies. 3. The F. P. Little Electric Construction & Supply Co., also in Buffalo.

1. The first-named firm bought the lamps from the Edison General Electric Co., and its successors the General Electric Company, exclusive licensees to manufacture under the patent. McLeod prior to such purchase had signed an agreement binding his firm not to sell any of the lamps so bought in violation of the various obligations which existed between the company and its licensees, and further agreed to keep himself informed of such obligations. The lamps in question were bought from the Edison Company upon an order of the firm, stating that they were "for use above 70th Street." They were sold to defendants by McLeod without restriction.

2. The Jaynes Electric Co. bought the lamps it sold to defendants from the Buffalo General Electric Company. This corporation obtained them from the General Electric Company, under a contract which authorized it to sell such lamps only to users of lamps within the County of Erie, except Tonawanda. The Jaynes Company bought the lamps from the Buffalo Company without restrictions, and sold them to defendants in like manner.

3. The F. P. Little Company bought the lamps it sold to defendants from the General Electric Co. through its Syracuse agent. It had previously signed an agreement similar to that executed by McLeod, but in making the sale to the defendants imposed no restrictions.

No doubt the defendants were advised in a general way that the complainant the Illuminating Company claimed that it had the sole right to use, and sell for use, lamps of the patent within the City of New York, but there is no reason for discrediting their statements that as to these particular lamps they had no notice or knowledge of any restrictions placed upon those who sold them.

Under these circumstances I am of the opinion that under the principles laid down in *Adams* v. *Burke*, 17 Wall 453 and *Hobbie* v. *Jennison*, 149 U. S. 355, the defendants have the right to use the lamps they bought anywhere in the United States. Concededly they were made by the General Electric Company, the exclusive licensee under the patent, and were sold by it to persons to whom it had the right to sell. The last-cited case reiterates the proposition that the "sale of a patented article by an assignee within his territory carried the right to use it everywhere." * * "*Once lawfully made and sold* there was no restriction on the *use* to be implied. for the benefit of the patentee or his assignees or licensees." The dissentients in *Adams* v. *Burke* and many Circuit Judges in subsequent decisions clearly and forcibly pointed out the result of such a construction of the patent laws, as would leave a patentee, who wishes to divide his rights territorially, dependent upon the good faith of those to whom he sells. But the Supreme Court has so held, and there is nothing for this Court to do but to conform to such decision. The patentee's remedy is against those who. after binding themselves to conform to his restrictions, have violated their agreements. He may protect himself either by selling his lamps only to persons on whose honesty and responsibility he can rely, or by requiring from them sufficient security, that they will respond for any damages he may sustain by their failure to keep faith with him. The purchaser of lamps once sold by the patentee, or the person whom he authorizes to make and sell them, cannot under the decisions *supra*, be charged with knowledge of the restrictions upon re-sale which are matter of agreement between the patentee or the licensed manufacturer and the first purchaser.

Motion to punish for contempt is denied.

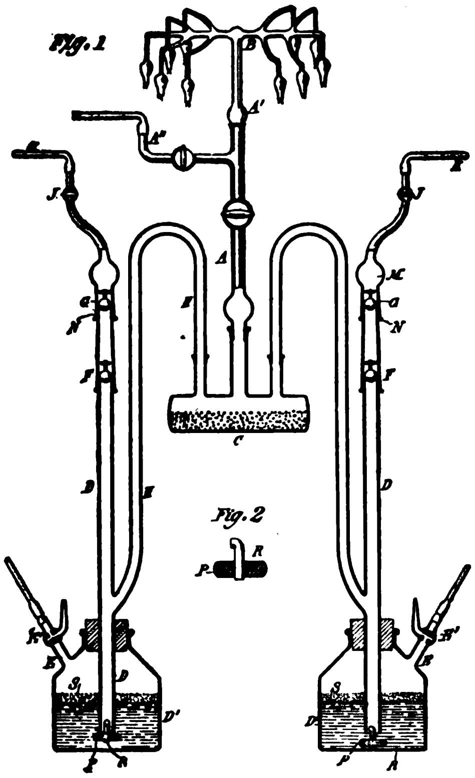
METER INSPECTION IN CANADA.

At the instance of some of the principal electric light companies, the Canadian Government has decided to establish a system of inspection of electric meters similar to that already in force for gas meters. A bill for this purpose is to be introduced in Parliament at the approaching session.

THE ASHWELL AND VANDERGRIFT "TUBULAR" MERCURY PUMP.

THE manufacture of incandescent lamps has greatly stimulated the study of, and given rise to numerous modifications in, the mercury pumps for exhausting the lamps, but it would seem that there was still room for improvement when it is considered that with the best Geissler pumps in use in one of our largest lamp factories it is necessary to keep the lamps on the pumps for three hours, and this even with the aid of mechanical pumps which remove the greater part of the air to begin with. It is evident therefore that if the time required for exhaustion could be reduced, the cost of the equipment and the operation of a lamp factory could be correspondingly reduced. It was with this idea in view that Mr. R. P. Ashwell, of Newark, N. J., and Mr. James A. Vandergrift, of New York, undertook to devise a mercury pump which should operate faster and hence cheaper than the present forms, and their long experience in the lamp works of the Sawyer-Man Electric Co. has greatly aided them in the solution of the problem.

The principle of the pump, which is of the Geissler type, will be readily understood by reference to the accompanying illustrations. Here A is a vertical tube with a ground orifice A' into which the stem of a cluster of lamps B, which are to be exhausted, is fitted. The tube A has a branch A'' through which the preliminary exhaustion of the lamps and the interior of the pump is effected by a mechanical or power pump. The high vacuum or mercury pumps are connected with the tube A through the usual receptacle C for an anhydrous absorbent. As both of the mercury pumps are of the same construction, a description of one will suffice for both.



FIGS. 1 AND 2.—THE ASHWELL AND VANDERGRIFT "TUBULAR" MERCURY PUMP.

D is a vertical tube the lower end of which extends down into a mercury reservoir D' through an air-tight seal. From the upper part of the reservoir D' runs a tube E divided into two branches, one connected with the mechanical exhaust pump, the other open to the air. These branches are controlled by a three-way cock E'. The interior of the tube D is of as nearly as possible uniform diameter to its upper end, which is contracted and connected by a tube K with a mechanical exhaust pump. A cock J is placed in the contracted portion of the pipe D at a point somewhat more than thirty inches above the lowest level of the mercury in the reservoir D', and below the cock and in the uncontracted portion of the tube D are two automatic valves F G. At a point slightly above the reservoir D' the tube D is branched, and connected by an inverted U-shaped tube H with the receptacle C. The highest point in tube H is somewhat over thirty inches above the line of lowest normal level of the mercury in the reservoir D', or a little above the highest level to which the mercury rises in the tube D.

By the mechanical or power pump the air is partially exhausted from the interior of the apparatus through the tubes A'' and K. Air is then admitted into the reservoir D' above the mercury which causes the latter to rise in tube D. When its level reaches the branch to tube H, a certain portion of the residual air is intercepted in the upper part of tube D and is forced by the rising column of mercury up through the valves F and G into the exhausted chamber to which the pipe K is connected. The mercury flows up around the valves F and G, rising until the air bubble is properly expelled, and at the same time flows up in tube H to a point sufficiently below the bend to prevent its passing over into the receptacle C.

While this operation is taking place in one of the pumps the reverse occurs in the other. That is to say, the air is exhausted from the reservoir D' by the mechanical pump so that under the more nearly equal pressures the mercury descends from the pump and flows back into the reservoir D'. The valves F G are loaded so that they seat themselves when only sufficient mercury is left above them to partially cover them. These actions go on alternately until the desired degree of exhaustion is attained.

In order to secure the best and most rapid operation of the pump it is necessary to carry out the feature of uniform diameter of tube D to the extent of so constructing the valves F and G that there will be a practically unobstructed passage for the mercury through them, and for this purpose, instead of seating these valves in contracted portions of the tube, the valve chamber M, or that portion of the tube containing the valve, is made with a ground opening which fits over the ground end N of the section of tube below it and seat the valve directly upon the open end N. The tubes are not contracted at all, or at least to any material extent.

Inasmuch as the tube D affords a free and unobstructed passage to the mercury, the too sudden or accidental admission of air to the reservoir D' would cause the mercury to rush up the tube D and through the valves F G with considerable violence. It is therefore necessary to check the flow of mercury from the reservoir into the tube D. But it is desirable that the return of the mercury should be free and unobstructed; hence between the reservoir and the tube there is interposed a rubber washer P, shown enlarged in Fig. 2, through which extends a contracted glass tube R, the upper end of which is bent over to prevent the mercury from squirting up into the tube. This prevents too rapid a flow of mercury into the tube but allows it to return freely back into the reservoir by lifting the valve bodily away from the end of tube D which forms its seat.

In these pumps it has been usual to pass the air admitted to the mercury reservoir through some material that would absorb the moisture contained therein, but this has not proved altogether effective. Messrs. Ashwell and Vandergrift find that they can secure very much better results by placing on the mercury within the chamber an absorbent S, that will float on the mercury. In this way the mercury is fully protected from direct contact with the inflowing air, and as the mercury flows back from tube D it surges up through the absorbent and is thoroughly dried.

In the pump as designed for regular service the tube D is 2 inches in diameter and with the duplex arrangement shown, 20 lamps can be exhausted in 20 minutes, the pump making easily no less than 8 strokes per minute.

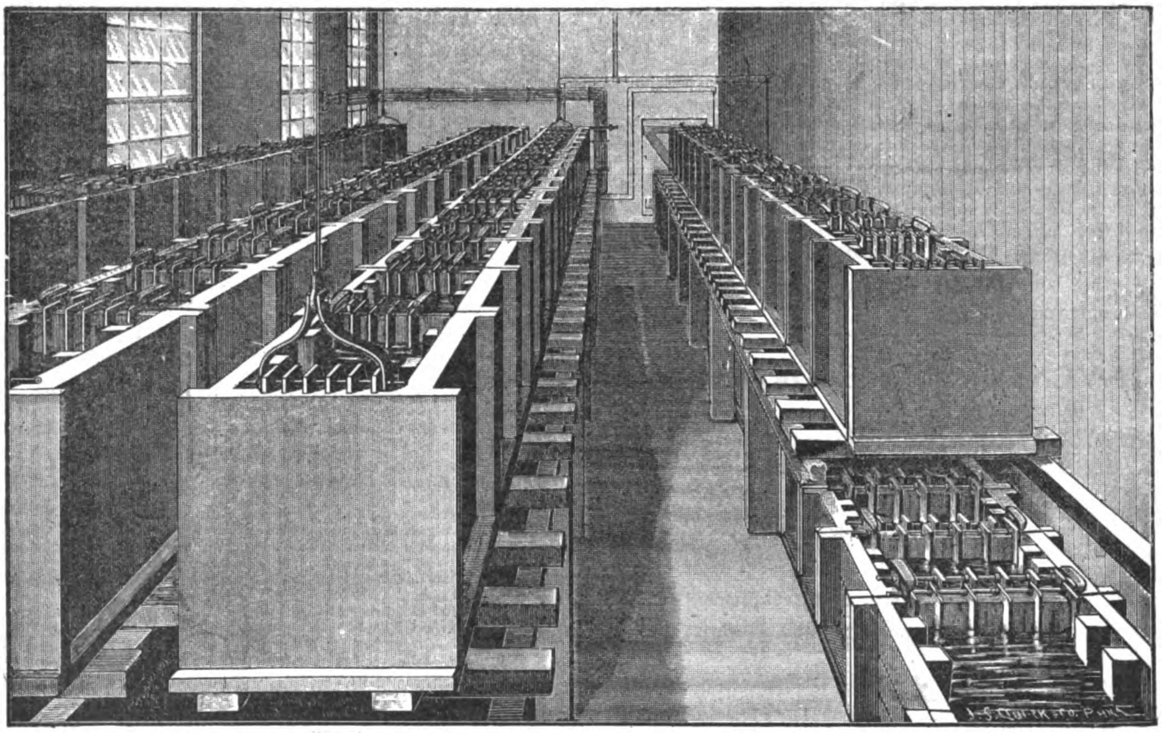
It is evident that with such a rapid pump the a large reduction in the equipment and cost of manufacture can be effected and calculations based on actual results already attained shows that the number of pumps, capacity of engine, boiler and dynamo and floor space occupied can be reduced to one-fifth that required by the present style of pump employed. When it is considered that the pump department often occupies 80 per cent. of the space in a lamp factory and that the power required in the pump department bears a like ratio to the total required, the saving which can be effected is obvious. We may add that the new pump has been recently patented.

ACCUMULATORS IN CENTRAL STATIONS.

THE accompanying illustration shows a storage battery installation made by The Electric Storage Battery Company at the station of the Germantown Electric Light Company, of Philadelphia. This battery consists of one hundred and twenty elements of the Chloride Type G, eleven plates each. They are installed on the three-wire system, and have a normal discharge rate of one hundred amperes on each side, and a capacity at this rate of 2,000 ampere hours. The plates are protected by the improved asbestos insulation, and are contained in lead-lined wooden tanks set on glass insulators, and supported on strong stands, painted with acid-proof paint, in four rows of two tiers each.

The special application of a battery in this instance is for the purpose of carrying the day load of the station for the commercial lighting and power circuit. The engines are shut down at daylight and the battery carries the whole load until dusk, at which time it is thrown out of circuit, and is put into charge during the early morning hours, when the station load is light, and the cost of charging is practically nothing, as the machinery is more efficient, no extra labor being required during charge, and during discharge the working force of the station is considerably reduced, the battery requiring practically no attention. The potential is maintained in discharge by the cutting in or out of reserve cells, six of which are used on each side. The Germantown Electric Light Company, after over a year's experience with the chloride battery have thoroughly demonstrated the advantages claimed for a storage battery for central station purposes. In view of the large number of electric light stations in this country, which are to-day either running a day load at a loss or else furnishing no current at all during the daytime, the importance of demonstrating the advantages of applications of this character is clearly apparent, since a battery in such stations will often not only wipe out the loss, but show a profit, and enable the lighting company to furnish continuous service.

By the installing of a storage plant many small natural sources of power may be utilized in furnishing light and power; sources which otherwise are not available, because not large enough to supply maximum demands. The force of the tides of small water powers from irrigating ditches, and even of the wind, come under this head. To all of these applications the chloride accumulator is particularly adapted because of its enormous storing capacity and demonstrated durability and efficiency. In Paris, alone there are over 100,000 electric lamps supplied by chloride accumulators, as well as a large amount of electric power.



Chloride Accumulator Plant in the Germantown (Pa.) Electric Light Co.'s Station.

The chloride accumulator is built of any desired capacity by The Electric Storage Battery Company, of Philadelphia, who guarantee its operation as regards capacity, efficiency and cost of maintenance.

Letters to the Editor.

MORE ABOUT THE CHLORIDE ACCUMULATOR.

I have read the letter of Mr. Gibbs, President of the Electric Storage Battery Co., in your issue of this week.

Feeling that yourself and the public may be interested in getting the true facts in relation to the decision by the Court of Appeals in France sustaining the Faure patent, I ask to be permitted to once more trespass on your space in order to make clear what Mr. Gibbs endeavors to befog by the most specious casuistry, by stating that the price which Baron Rothschild paid for the French Faure patent was merely a "nominal consideration," and secondly, by endeavoring to make the reader of his letter think that the decision in France did not affect his battery. Now, the fact is, that the decision in France was directly to the point that the Chloride battery is an infringement of the Faure patent, and that the force of that decision was so strong against the Chloride Company that Baron Rothschild had to buy a controlling interest in the Faure Company, paying therefor 1,350,000 francs, besides the debts of the Faure Company. This sum may appear to Mr. Gibbs, whose Company is capitalized at $10,000,000, as a "nominal consideration."

The battery which was enjoined by the French decision is substantially similar to the Chloride accumulator, and in *no way* resembles the description which Mr. Gibbs' fancy attaches to it. It was the Pollak battery. To a lead support was applied sulphate of lead and chloride of sodium; Mr. Gibbs' company applies to a lead support chloride of lead and chloride of zinc. Pollak immersed his plate in a bath of chloride of sodium, containing a slab of metallic zinc, for the purpose of reducing the matter adapted to become active to spongy lead; Mr. Gibbs immerses his plate in a bath of chloride of zinc, in connection with a slab of metallic zinc, in order to reduce the matter adapted to become active to spongy lead; so that we have in each case salts of lead applied to a lead support, in each case immersed in an equivalent bath with a metallic zinc slab, for the same purpose, to-wit, to reduce the active matter to spongy lead. The Court of Appeals of France held that the Faure invention covered salts of lead as well as oxide of lead, and that Pollak could not escape infringement by the double process above described. The Court says that the first process was but a preparation of the plates, and the moment the two plates were combined in the acidulated electrolyte, Pollak became an infringer of the Faure invention.

A copy of the decision can be seen at my office; also my authority for the statement of the payment which Mr. Gibbs calls a "nominal consideration."

Wm. Bracken,
President Consol. Elec. Storage Co.

New York, March 9, 1894.

THE STORAGE BATTERY CHALLENGE.

To all those sincerely interested in the advancement of electrical arts, there is something deplorable in the exhibition to which we are invited by the challenge of the Electric Storage Battery Company now being advertised, but it is not likely that any respectable business competitor of this company will enter a match for five hundred dollars a side. It is well known that public opinion is the only jury before which great issues can be determined, and it is just as impossible for Messrs. Houston and Kennelly to award these stakes to the best storage battery, as for one expert to pick out the greatest artist or the greatest poet of the ages.

Dr. Johnson himself did not venture to pronounce Shakespeare a great poet on his own authority, but required the test of time and public opinion, saying, "The sand heaped by one flood is scattered by another while the rock remains continually in its place. The stream of time which is continually washing away the dissoluble fabrics of other poets passes without injury by the adamant of Shakespeare."

The stream of Time can be counted on to wash away all the worst fabrics of storage battery development, and leave whatever is best, regardless of laboratory prize fights, even when men of scientific distinction hold the stakes.

Since, however, the proposed conditions will be widely read they are deserving of at least some criticism. The chloride claims to be 50 per cent. better than any other and yet this is qualified by the experts to mean $\frac{50}{300}$ instead of $\frac{50}{100}$. It would be very easy to construct a series of tests between two types of batteries so as to show an apparent superiority of 14 per cent. in favor of either. Now it is true although evidently not understood by the experts that if a competing battery had equal capacity per weight, equal efficiency and only ⅔ of the life of the chloride, that the latter would be 50% better, but who would claim that if efficiency and life were equal and the capacity per weight only $\frac{2}{3}$ that the chloride would be 50% better. A Planté battery equal in all other respects to the chloride might have a capacity per weight of $\frac{2}{3}$ and yet cost but half as much, and after it was worn out it might be worth 50 per cent. more; so that the cost to the owner would be less than half of the chloride for life and efficiency. Yet Mr. Gibbs would claim under the proposed conditions that his battery was 50% better. Does it not seem that these conditions were drawn up to insure the stakes of this prize ring to the chloride battery even if it were only half as good as its competitor? Among many questions that occur to me I might ask the following. What is meant by electrode? How much of the conductor, the supports or the active material does it include? Might it not also refer to the electrolyte? To what extent in terms of E. M. F. are the 100 preliminary discharges to be carried? Why is the discharge to be carried as low as 1.75 volts, and how does the E. M. F. fall on opening the circuit? What "is point of full charge"? Why is 1.75 volts fixed? Is it to exclude the Lalande-Chaperon type? Is it in order to ruin Planté batteries? What about zinc-lead batteries? "The durability is to be measured by determining the number of working hours of charging and discharging at the rate of 2½ amperes per pound of dry electrodes as shipped, which will reduce the storage capacity of the batteries in ampere hours to one-half of its first valuation at that point." What has this to do with annual cost? Do not negatives and positives have different lives and might not the ratio between their respective lives be affected by the treatment under which they are used?

ROBERT MCA. LLOYD.

NEW YORK, MARCH 10, 1894.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED FEBRUARY 27, 1894.

Accumulators:—

Secondary Battery, L. B. Rowley, Ashland, Wis., 515,502. Filed Feb. 7, 1893.

Consists of a combination of a series of tubes horizontally placed and supported at their ends and having spaces between them for the circulation of the electrolyte.

Alarms and Signals:—

Electric Railway Signal, H. V. Riley & Chas. Selden, Baltimore, Md., 515,366. Filed Oct. 5, 1893.

An automatic electric grade crossing signal for steam railways.

Auxiliary Fire Alarm Telegraph System, J. Sachs, New York, 515,508. Filed Feb. 15, 1893.

Signaling Apparatus, O. D. & M. A. Kleinsteuber, Milwaukee, Wis., 515,589. Filed Apl. 8, 1893.

A police signal consisting of a steam or compressed air whistle actuated by an electric circuit.

Electric Alarm System for Railway Crossings, A. J. Wilson, Port Chester, N. Y., 515,638. Filed Apl. 25, 1893.

Automatic Electric Railway Signal System, C. P. Breese, New York, 515,648. Filed March 22, 1893.

An electric block signal system for steam railways.

Signaling Apparatus, J. W. English, New York, 515,665. Filed Oct. 26, 1893.

An electric visual signal exhibiting at will letters, figures, etc.

Conductors, Conduits and Insulators:—

Insulating Thimble, I. A. Brown, Toledo, O., 515,321. Filed April 5, 1893.

Designed to cover the handle of the regulating device on an electric car.

Wire Coupling, D. A. Byers, Denver, Col., 515,420. Filed March 13, 1893,

Consists of an open ended tube enlarged interiorly and a detachable plate covering an opening leading to the central chamber.

Fixing Electric Conducting Wires to Insulators Supporting Same, R. Schomburg, Berlin, Germany, 515,448. Filed March 29, 1893.

Employs a binding piece adapted to hold the wire in position without the use of tie wire.

Distribution:—

Regulator for Continuous Current Arc Light Circuits, D. Higham, Boston, Mass., 515,473. Filed May 14, 1892.

An electromagnetic device responding to wave variations of current combined with a second device responding slowly to variations of mean intensity of current.

Dynamos and Motors:—

Dynamo Electric Machine, J. Wenstrom, Orebro, Sweden, 515,386. Filed Mch. 6, 1893.

Claim 1 follows:

In a dynamo electric machine the combination with the two poles of a field magnet, of an armature attached to one of said poles and having a continuous uninterrupted surface adjacent to the air gap, and a keeper of solid magnetic material revolving in the air gap between the said armature and the other pole.

Armature for Electric Machines, W. Fritsche, Berlin, Germany, 515,467. Filed July 1, 1893.

Comprises a core built up of a series of interspaced angular elements arranged radially on a hub and forming a cylinder of variable diameter and conductors interposed between the elements of that portion of the cylinder of greatest diameter in the planes substantially parallel with its axis.

Electric Motor, C. Doriot, Philadelphia, Pa., 515,488. Filed Mch. 11, 1893.

Claim 1 follows:

The combination with the motor frame having the base portion projecting at one side, of the belt guide pulleys mounted on said projecting portion.

Current Collector for Dynamos, O. R. Roberts, Addison, Pa., 515,613. Filed Aug 21, 1893

Consists of two endless belts of conducting material supported by adjustable sheaves.

Galvanic and Thermo-Electric Batteries:—

Primary Battery, C. J. Hubbell, Boston, Mass, 515,432. Filed May 31, 1893.

Employs a zinc element having a stud of metal projecting centrally from it and extending downward into a mercury cup which is connected with one of the binding posts.

Heating:—

Electric Heater, A. S. Hatch, Windsor, Can., 515,401. Filed Mch. 27, 1893.

Consists of a series of frames fastened to a face plate but insulated from one another and having a heat developing conductor wound spirally upon them.

Electric Heater, S. E. Nutting, Chicago, Ill., 515,693. Filed Apl. 27, 1893.

Claim 1 follows:—

An electric heater, composed of electric wires provided with terminals embedded in a non-conducting cement and between two layers of a flexible non-conducting material, in combination with an outer covering of textile fabric.

Lamps and Appurtenances:—

Electric Arc Lamp, G. Kirkegaard, Brooklyn, N. Y., 515,342. Filed June 19, 1893.

Claim 1 follows:—

In an arc lamp, a pivoted frame carrying a clockwork and escapement, the the escapement being located in one of two planes perpendicular to each other, one of which planes is vertical, the pivot of the frame being at the apex of the two planes.

Electrical Glow Lamp, H. Cottrell, Newark, N. J., 515,465. Filed Mch. 30, 1893.

A lamp illuminated by an electro magnetic discharge effected by applying a coating of tin foil or the like to the surface of an exhausted glass bulb and connecting the coating with a circuit adapted to induce an electro magnetic discharge across the interior of the bulb.

Socket for Incandescent Lamps, L. Stirn, New York, 515,484. Filed June 22, 1892.

A socket containing a ratchet switch actuated by pulling a cord.

Lamp Socket, L. Stirn, New York, 515.485. Filed Nov. 18, 1892.

Similar to No. 515,484.

Incandescent Lamp Socket, R. C. Nourse, South Framingham, Mass., 515,606. Filed May 31, 1893.

Metal Working:—

Apparatus for Electrically Heating or Working Metals, C. L. Coffin, Detroit, Mich., 515,652. Filed Feb. 9, 1893.

Claim 1 follows:

An electric arc metal working apparatus comprising electrodes for the passage of current and an arc disturber with mechanism for changing its relation to the electrodes during work.

Metallurgical:—

Method of Peroxiding Lead, W. W. Griscom, Haverford, Pa., 515,383. Filed July 17, 1893.

Employs an electrolyte of water, sulphuric acid and nitric acid in which the ratio of sulphuric to nitric is more than three to one.

Miscellaneous:—

Electric Gas Lighter, J. O. Dahlgren, Boston, Mass., 515,397. Filed Dec. 30, 1893.

Insulated Pipe Coupling, G. Peeples, Philadelphia, Pa., 515,716. Filed June 5, 1893.

Railways and Appliances:—

Bond for Electric Railways, J. Meyer, New York, 515,478. Filed Oct. 21, 1893.

Claim 1 follows:

The combination, with the rail ends, of metallic plates located below the rails and provided with downwardly extending lugs, and bonds connecting said lugs.

Conduit Electric Railway, J. A. Cassidy and W. A. Butler, New York, 515,572. Filed Aug. 24, 1892.

A sectional conduit railway whereby the passing car operates a toggle joint making contact with the line conductor.

Electric Railway. B. F. Comstock, Decatur, Ill., 515,654. Filed April 13, 1893.

A double track railway operated from a single trolley wire placed between and above the track and means for enabling two trolleys running in opposite directions to pass one another on the single wire.

Switches and Cut-Outs:—

Electrical Controller, E. A. Sperry, Cleveland, O., 515,374. Filed Aug. 23, 1893.

Claim 5 follows:

In an electrical controller, a switch, a handle for the manual operation of said switch, a main moving element for the controller provided with a separate handle, two sets of stationary and moving contacts, one controlled by each handle, those of one set being in series circuit relation with those of the other, a lock for the switch, and means connected with the main moving element for actuating such lock.

Telegraphs:—

Telegraphic Instructor, T. J. Houck and H. M. Browning, Baltimore, Md., 515,709. Filed Sept. 21, 1893.

Telephones and Apparatus:—

Switch and Circuits for Telephone Exchanges, J. J. O'Connell, Chicago, Ill., 515,531. Filed April 17, 1893.

Claim 1 follows:

The combination with a plug cord and with the contact terminals of an electric circuit of a circuit changer arranged to be shifted by said cord as the latter is moved.

A GOOD TEST OF IDEAL WIRE.

At the National Electric Light Convention, at Washington, D. C., were seen two coils of "Ideal" insulated wire, each 25 feet in length, No. 16 B. & S., soaking in water with the incandescent light circuit passing through them. These coils were, on invitation of Messrs. Queen & Co.'s representative taken to their laboratory in Philadelphia and tested to ascertain the "drop" between the two. The result of these tests has been furnished the Phillips Insulated Wire Company in a carefully made report by Mr. Willyoung including diagrams, etc., the gist of which is as follows:

With the top coil resting on the lower in water by its own weight, there was no loss or leakage that could be measured between the two coils. With the top coil weighted down by ten pounds pressure an escape of one tenth of one volt was found. The voltage used was 100 and we are informed the coils had been previously soaking in water over two months. This speaks well for a wire with no rubber or gutta percha in its insulation.

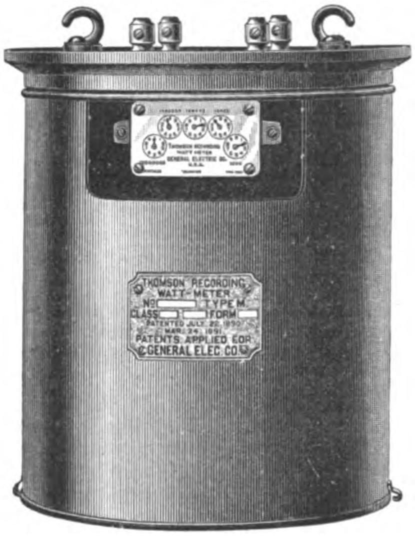
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THOMSON RECORDING WATTMETER FOR ARC CIRCUITS.

THE success which the Thomson wattmeter for incandescent circuits has experienced, has prompted the General Electric Company to design a recording wattmeter especially for the measurement of energy used in groups of arc lights in commercial lighting such as in stores, factories, halls and the like. This meter is the outcome of two and a half years of careful investigation and experiment. Indeed, probably no other meter or instrument manufactured by the General Company has received more careful study than this. It is a true wattmeter, modified in its principles only to meet the change of conditions of arc light service. It is similar in construction to the well known Thomson recording wattmeter, and has the same damping device—a copper disc and two permanent magnets.

It has been designed on the lines of an arc lamp so far as its location, etc., are concerned, that is to say, to be suspended from the ceiling by two brass rods fastened to a simple ceiling board, and the same object is attained as in the suspension of arc lamps from the ceiling—the meter is inaccessible except to those who understand its manipulation. A special feature of the meter is the safety cut-out contained within the cover proper. It is designed to close immediately on possible trouble occurring within the meter which might result in the burning out or breaking of the circuit. The cut-out serves to short circuit the meter and cut it out, rendering trouble in the meter impossible. At the same time it preserves the continuity of the circuit and permits the lights to burn without interruption, an advantage sufficiently obvious.



THOMSON RECORDING WATTMETER FOR ARC CIRCUITS.

The connections of the meter are exceedingly simple. The connection blocks are at the top, the wires being brought first to the ceiling board and then dropping to the meter. The two terminals farthest from the front of the meter are connected to the line through an absolute cut-out, the two front terminals being connected to the lamps in the house.

So far as the operation of the meter is concerned, it makes no difference which wire is positive and which negative, though, of course, to have the lamps burn correctly attention will have to be paid to this point. No trouble will be caused if the linemen should make a mistake and connect the wires which should go through the front terminals to the back, and vice versa; there will be no short circuit or burn out. The meter will run backwards but register correctly, subtracting instead of adding to the sum on the dial. The meter is shipped fully assembled and ready for installation. Careful tests show that the same high accuracy can be expected on a minimum load as on a maximum.

FORD AND BACON.

This firm, composed of Messrs. F. R. Ford and G. W. Bacon, both formerly with the La Roche Electric Works, has recently been formed, with offices in the Philadelphia Bank Building, 421 Chestnut street, Philadelphia, Pa. Electrical supplies will be handled and manufacturers who are not now represented in that city are invited to communicate with the company. The experience of both partners, together with their wide acquaintance, places them in an advantageous position to secure and retain a good business.

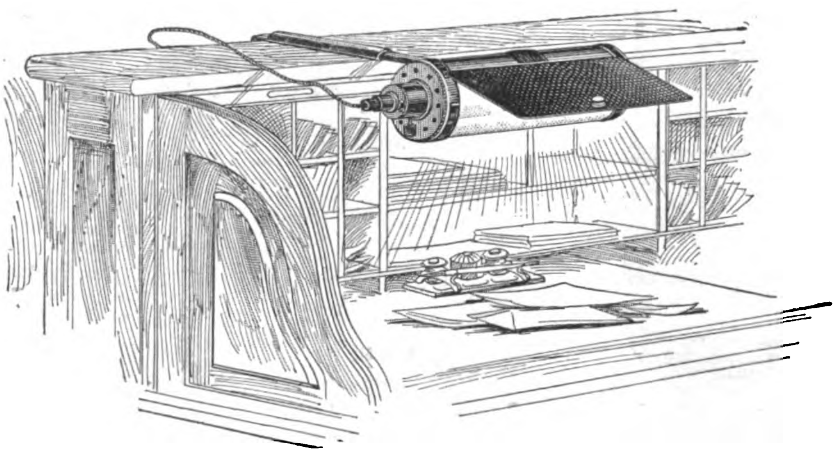
THE HORNBERGER ELECTRIC MFG. CO.

Elkhart transformers up to date form the theme, and in fact the entire subject matter, of a tasteful catalogue issued by the Hornberger Electric Mfg. Co., of Elkhart, Ind. The construction, installation and merits of the tooth type converter is treated of in a manner at once concise, clear and convincing, and several pages are filled with excellent testimonials from a number of well known companies and individuals throughout the country.

THE KINSMAN DESK LIGHT.

THE accompanying illustration shows the Kinsman desk light introduced by McLeod, Ward & Co., of 91 Liberty street, New York. It is entirely novel, and has many advantages. It is clamped on the desk as shown, without marring or interfering with the desk in any way, and has an adjustable arm which enables the cylinder to be pushed back or drawn forward as desired. The inner glass cylinder is so arranged that the light can be modified in intensity by a slight touch and the whole apparatus can be operated without rising from the chair.

These lamps are just as well adapted to music stands or upright pianos, to the illumination of paintings, etc., and can also be arranged to suit special desks or tables. It also contains an adjustable student's shade, which, while it shields the eyes, also acts as a reflector to light the desk.



THE KINSMAN DESK LIGHT.

ST. LOUIS NOTES.

MR. A. W. DUTTON, long and favorably known in connection with the Brush interests and later with the Short Electric Railway Co., has been appointed Southern agent for Texas and Louisiana for Leonard & Ellis. Mr. Dutton will make his headquarters at Houston, Tex.

THE ACME FILTER CO. are not complaining of lack of orders for their oil economizers, and speak in high terms of THE ELECTRICAL ENGINEER as an advertising medium, saying that a small card placed in our columns some time ago brought them replies from all over the United States.

THE ROSE ELECTRIC SUPPLY COMPANY are putting in an electric plant of twenty arc and 200 incandescent lamps at the rolling mills of the St. Louis Stamping Company on Second and Destrehan streets, in the north end of the city; they are also furnishing a 500 light alternating plant for Angola, Ind.

ALLEN & ALLEN is the style of a new firm in the electrical contracting business, with offices in the Roe Building. Both were until recently members of the St. Louis Electrical Engineering Co., have a wide acquaintance, and with their long experience in the business should have no trouble in securing all the work they can handle.

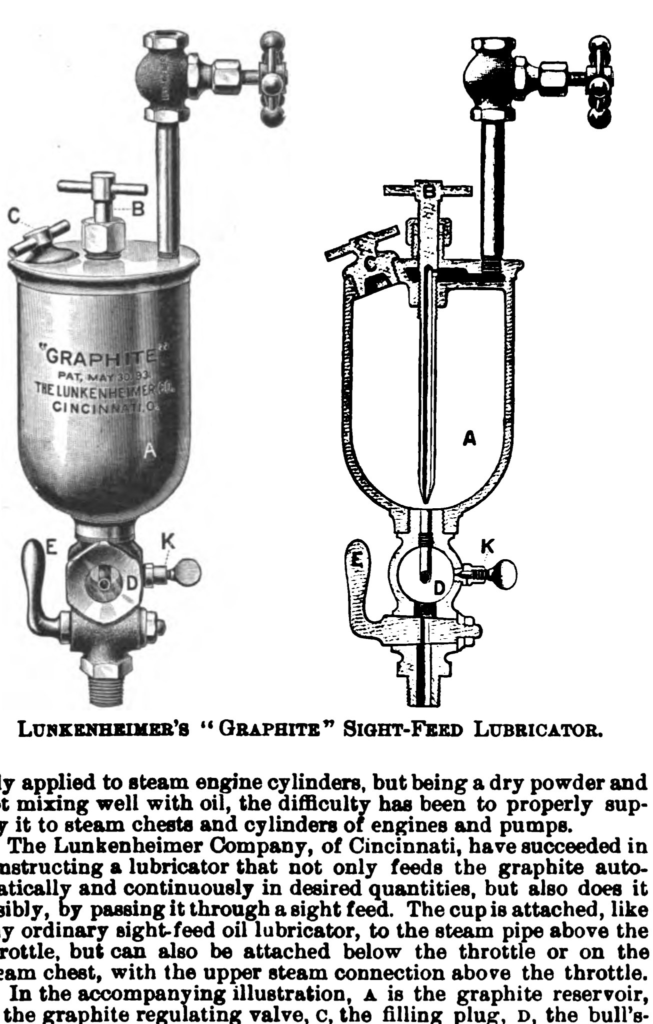
MR. LOUIS NAHM, secretary and general manager of the American Electric Mfg. Co. reports a good demand for their high grade "American" lamp, notwithstanding that a slightly higher price is charged for it on account of the superior material in its construction. This lamp is guaranteed to last 1000 hours while their regular "Republic" lamp is, they claim, the standard 600 hour lamp.

Jas. I. Ayer & Son, electrical and mechanical engineers, although established but a short time, are already so busy that a good deal of "midnight current" is being consumed at their offices in the Security Building. Messrs. Ayer & Broughton are getting out plans for an improved form of boiler setting for the regular horizontal tubular boilers, in which are incorporated some ideas due to many years' practical experience in the operation of the largest lighting station in the country.

Columbia Incandescent Lamp Co. All departments of this company are in full operation and in the shipping room more than ordinary activity prevails. The company are constantly putting in new labor saving machinery of their own invention, which will not only expedite the manufacture of lamps, but also secure more uniform results than ever. The Columbia Co. have recently secured the services of Mr. J. E. Randall, who was for seven years connected with the Thomson-Houston Co. at Lynn, in their lamp department.

LUNKENHEIMER'S "GRAPHITE" SIGHT-FEED LUBRICATOR.

It is well known by engineers generally, that pure flake graphite is far superior to oil or any other lubricant, when properly applied to steam engine cylinders, but being a dry powder and not mixing well with oil, the difficulty has been to properly supply it to steam chests and cylinders of engines and pumps.



Lunkenheimer's "Graphite" Sight-Feed Lubricator.

The Lunkenheimer Company, of Cincinnati, have succeeded in constructing a lubricator that not only feeds the graphite automatically and continuously in desired quantities, but also does it visibly, by passing it through a sight feed. The cup is attached, like any ordinary sight-feed oil lubricator, to the steam pipe above the throttle, but can also be attached below the throttle or on the steam chest, with the upper steam connection above the throttle.

In the accompanying illustration, A is the graphite reservoir, B, the graphite regulating valve, C, the filling plug, D, the bull's-eye sight feed chamber, E, the feed regulating valve, and K, the drain valve. The operation will be readily understood without further description. The cups are made of the best materials, thoroughly tested and fully warranted.

NEW YORK NOTES.

The Okonite Company, Ltd. will as usual be represented at the Convention. Capt. Willard L. Candee and Mr. Geo. T. Manson, will be on hand.

Messrs, Warren & Burhorn, of 136 Liberty street, New York, have been appointed consulting engineers to draw up plans and specifications for a complete isolated electric light plant, to be installed in the State Insane Asylum at Trenton, N. J. The plant will include engine, possibly direct connected, and wiring complete for about 1,000 lights. The Trenton Asylum with others, is under the control of the State Board of Managers of Asylums.

Mr. Walter S. Dix, formerly connected with the Crocker-Wheeler Elec. Co. has accepted a position as special sales agent for the Holtzer-Cabot Electric Co. with offices at 143 Liberty st.

The Perkins Electric Switch Mfg. Co., Hartford, Conn., have leased the entire property and plant of Waterhouse, Gamble & Co., and will continue the manufacture of that concern's well-known arc lamp. They are ready to receive orders for any quantity of arc lamps for incandescent circuits.

The Abendroth & Root Manufacturing Company, 28 Cliff st., New York city report a brisk demand for their Root improved water tube steam boiler, with recent orders of 248 h. p. for the Para Electric Light Company, Brazil; 2,000 h. p. for the tunnel plant of the Baltimore & Ohio Railroad, at Baltimore, Md.; 4,000 h. p. for Cincinnati Street Railway Company, and two large boilers for the Flatbush Gas Company, Flatbush, Long Island.

Mr. W. J. **Morrison**, agent for the Fort Wayne Electric Co., with headquarters at Syracuse, has sold a 750 light Wood alternating plant to C. F. Prentice, Le Roy, N. Y., where that gentleman has just completed a 400 H. P. water power installation, intended for central station light and power work. The Batavia, N. Y., board of alderman has also voted for an addition to the plant of 120 Fort Wayne lamps with dynamo, poles, wire, etc. Wood apparatus will be used.

Ideas Protected. Mr. Edward P. Thompson's "caveat" system consists of an attestation and legal execution of the gist of an invention before the proper officer as soon as possible after it is conceived. The document is then deposited in his safe and a certificate is given to the inventor. Two advantages are gained. The inventor may take more leisure in deciding about applying for a patent and in perfecting the details, and yet be confident of proving legally, when he made the invention; and secondly, the cost is only a mere trifle as compared to that of a regular Patent Office caveat. It is not so difficult to make an invention as it is to be the first in point of time; hence the advisability of getting the earliest possible dates fixed for all inventions and gradually sifting out the most important as subjects for patents. Mr. Thompson's address is Temple Court, N. Y.

WESTERN NOTES.

Mr. Jno. M. Fordham, the representative of the Bridgeport Brass Co., New York, was in Chicago last week.

Metropolitan Elevated Railway, Chicago.—It seems to be definitely decided now to use electricity as the motive power on this line.

La Roche Electric Works, Mr. Wm. Hood, Chicago agent, report the sale of a 1,300 light alternator to the Hammond, Ind., Light and Power Co.

"O. K." **Weatherproof** line wire is rapidly gaining ground as a leading weatherproof wire, and the Electric Appliance Company state that each month shows a large increase in their sales of this leading specialty.

Metropolitan Electric Co., Chicago. Since taking the general sales agency of the P. & B. compounds a most gratifying increase in the sales has resulted, the company having secured some very large orders recently.

Mr. J **Holt Gates**, Monadnock Building, Chicago, is installing a 1000 light Waddell-Entz direct current dynamo in the Hartford Building. The machine is of their well known slow speed type, coupled directly to a 12 x 12 automatic Cooper engine. A steam pressure of 115 lbs. will be used.

The Electric Appliance Company, without making very much hurrah about it, have been quietly building up a very nice trade on the Acme tape, a specialty which they first placed on the market something over two years ago and which has stood the test of time and made many friends.

Geo. Cutter, Chicago, reports a growing demand for the Pass & Seymour china wiring and window tubes, of which he is carrying a large stock at Chicago. Being thoroughly waterproof, they comply with the most rigid inspection rules and insure high insulation at all times. The scrutiny of work around Chicago is becoming more and more severe.

Mr. E. F. Seixas, for a long time identified with the Edison interests and later with the *Street Railway Gazette*, has entered the offices of Mr. J. L. Barclay, at 1645-8 Monadnock Building, Chicago. Mr. Seixas will especially exploit the street railway apparatus manufactured by the Walker Mfg. Co., of Cleveland, O. This company's reputation for high grade engineering work in street railway and power transmission will no doubt greatly benefit Mr. Seixas' efforts in this field.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

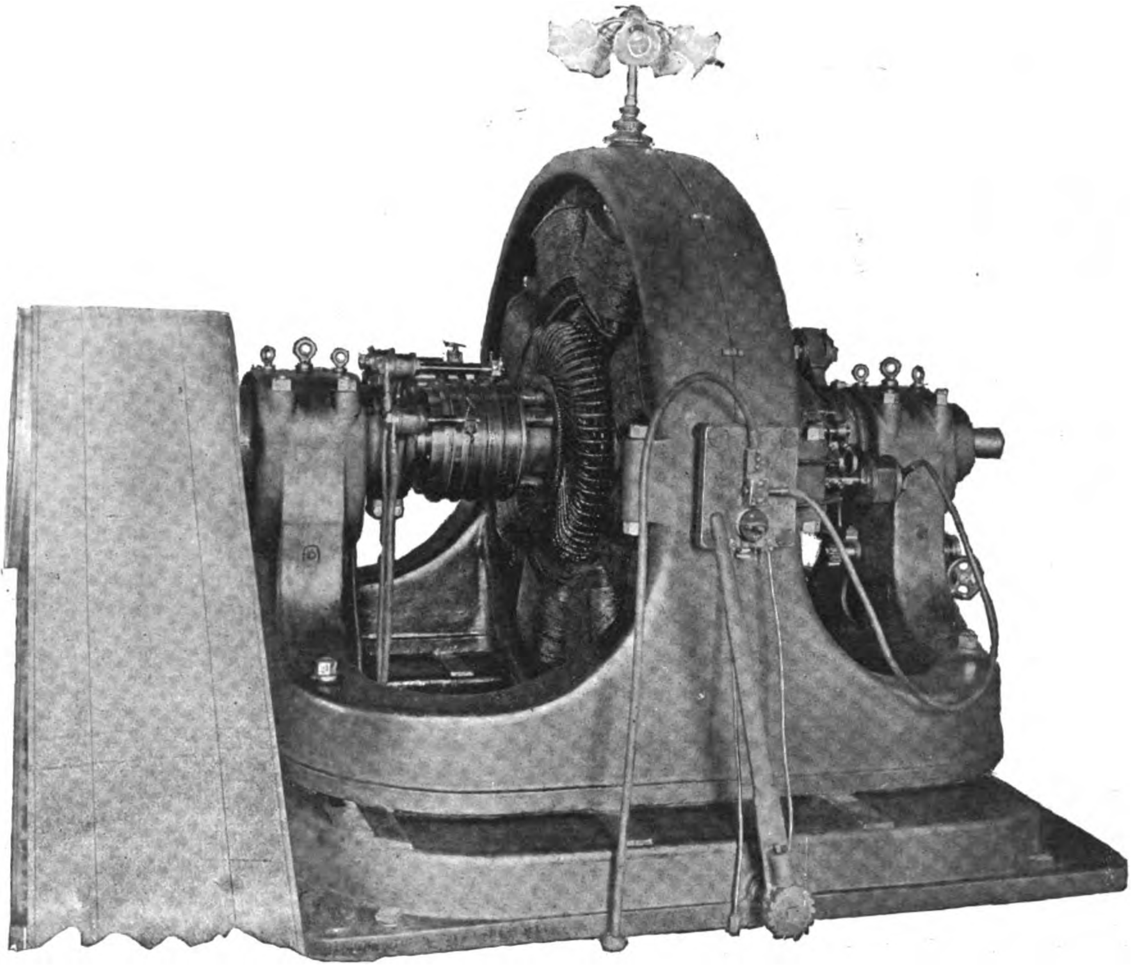
THE
Electrical Engineer.

Vol. XVII. MARCH 21, 1894. No. 307.

THE NEW WESTINGHOUSE COMBINED DIRECT AND ALTERNATING CURRENT GENERATOR AT ROCHESTER, N. Y.

BY

Jno. Dennis Jr.



The New Westinghouse Combined Direct and Alternating Current Generator.

THE Westinghouse Electric and Manufacturing Company has recently completed the installation of two generators of a new type, at the plant of the Citizens' Light and Power Company, at Rochester, N. Y., which apparently marks the beginning of a new departure in station operation. These two generators, which are exact duplicates, are the first of the type built, and the success in their operation is so marked that they seem to be worthy of more than passing notice.

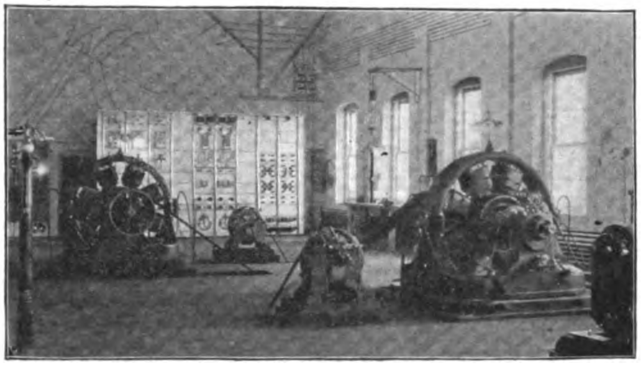
In the absence of a more specific trade name the machine may be called a combined direct current and alternating current generator. The peculiarity of this combination is that a direct current of 550 volts is taken from one end of the armature shaft and an alternating current of about 385 volts is taken from the opposite end of the shaft. In other words, the entire output of the generator may be utilized for direct current work, the entire output used for alternating current lighting and power purposes, or it may be divided between the two classes of work, in such proportions as may be desired.

The first impression produced by the new generator is its extreme simplicity of construction. The armature, which is essentially the same as the ordinary type of

Westinghouse single-wound iron-clad armature for street railway generators, revolves in an eight-pole field. It revolves at a speed of only 750 revolutions per minute, giving a frequency of 6,000 alternations per minute on the alternating side. The direct current end of the shaft is fitted with an ordinary commutator.

So far as the direct function of the generator is concerned, no explanation is necessary. The current is commutated in the usual manner, and does its work with indifference to the somewhat peculiar condition of affairs existing at the other end of the armature shaft. The alternating current side of the generator is arranged on the two-phase system; two alternating currents are delivered on two separate circuits, with a quarter-phase difference, thus enabling alternating motors to start with good torque.

The alternating current connection is made thus: The armature has a hollow core; the wires of the two-phase alternating circuits are given positive and negative connection to the commutator on the direct end of the shaft, the wires making suitable connections to collector rings on the alternate current end of the shaft. Thus, while the current is commutated and sent out from what I call the direct end of the shaft, the alternating currents are carried to the other end, and pass through the step-up transformers, on to the line, with the voltage increased to 2,000. The wires passing through the hollow core of the armature are bolted in the proper position to the back of the commutator.



Dynamo Room of The Citizens' Light and Power Company, Rochester, N. Y.

The fact that there is a voltage of only 385 at the alternating end and a voltage of 550 at the direct end seems to be a little perplexing. Possibly it is made a little clearer by the fact that in separate generators a direct E. M. F. is rated at its maximum, and an alternating E. M. F. is rated at the average of the curve, say seven-tenths; and obviously, the same rating must obtain when the different currents are combined in the novel way described above. The two-phase, four-wire systems are utilized in this combined generator and it is sufficient for the present to record the fact that all difficulty of equalizing the voltage on the circuit is obviated; in other words, it has been demonstrated that absolutely no balancing is necessary, a fact which will be duly appreciated.

It should be noted that, while the combined generator does all kinds of work except series arc lighting, the alternating feature gives all the advantage of transmission of current, besides bringing into use the important feature of self-starting alternating motors. It will be seen at a glance that, under these conditions, the generator is capable of work on the following lines: Direct current motor work; incandescent lighting by alternating current; alternating current motor work; alternating current arc lighting; street railway work. It is of course unnecessary to occupy space in pointing out the advantages to a medium-sized station, running night and day, on the various classes of work which have been enumerated, and the distribution of load from one end of the shaft to the other, at will, without shutting down.

Another element must not be lost sight of, and that is the safety of operators at the station, secured by the low voltage. The alternating current goes to the transformer with a voltage of only 385; a fact which tells its own story.

A description of these two combined generators, which are making such a sensation in electrical circles in Rochester, would not be complete without some reference to the model electric light and power station where they are installed and in successful practical operation. The station of the Citizens' Light & Power Company is situated below the Lower Falls, on the west bank of the Genesee River. The building is three stories high, having an entrance in the rear from the flats, and from Mill street by stairway from the front. The first or ground floor is sixty by fifty feet. It contains two 500 horse power turbines, with room for two more. It also contains one 500 horse power engine, with places for three more, thus duplicating the water power plant with steam power. Adjoining is the boiler room, ninety-one by forty-eight feet with a capacity of 2,000 horse power in boilers. Directly over the engine room is the shaft room, which is eighty-four by fifty feet, with four lines of shafting, so arranged that either line of shafting can be run from either water wheel or either engine. The water wheels are connected with the shafting by a rope drive. Above the shaft room is the dynamo room, ninety-four by fifty feet.

The building is thoroughly fire-proof, as the only wood used in the construction is in the floors. All the girders are of steel, with steel truss roof, and the walls are laid in Portland cement. The water is conducted from the race on Mill street to the turbines through a steel flume, seven feet in diameter, with a head of ninty-three feet. The building and shafting were constructed under the direction of Robert Cartwright, of Rochester.

The wires are brought into the building through a brick tower entirely separate from the building. Then the wires come to the switchboard through a two foot wall, with porcelain tubes. This was constructed when the building was erected.

In the dynamo room, besides the important combined generators described, are two sixty lighters, of the latest type made by the Western Electric Company, for arc lighting, and others are to be installed. The plant includes the latest improved Westinghouse combination panel switchboard, which is said to be superior to the one exhibited by that company at the Columbian Exposition, and to be the finest example of switchboard in the United States. The skeleton frame is of iron, the instruments being mounted on handsome marble. The instruments, which were designed and manufactured by the Westinghouse company, are of the latest type and most approved design. The switchboard is so designed that additional dynamo or feeder panels can be added without disturbing the parts already in position, or interfering with the operation of the plant.

The foresight and good judgment of the efficient superintendent of the Citizens' company, Mr. John A. Almstead, will be appreciated when the fact is made known that he visited Pittsburgh in company with General Manager E. M. Higgins, before a single pattern of the combined generators had been made, and virtually took the responsibility of the selection of the present system. That his judgment was a good one, is shown by the gratifying results, now that the plant has been fully installed and is in successful and singularly economical operation. The stockholders of the company are all prominent business men of Rochester. The officers of the company are: President, Robert M. Myers; vice-president, H. Wheeler Davis; secretary, H. Willis; treasurer, P. V. Crittenden; general manager, E. M. Higgins; superintendent, J. A. Almstead.

THE ELECTRIC RAILWAY AND ILLUMINATING PLANT OF THE MILWAUKEE STREET RAILWAY COMPANY.—II.

BY

Otto Frick

RAILWAY ENGINE ROOM.

THE railway engine room, Fig. 6, which is 95 feet long, 45 feet wide and 30 feet high, contains five sets of Edison triple expansion vertical engines, of 600 h. p., with two 200 kilowatt Edison multipolar dynamos keyed one to each end of the shaft. Two of the engines were built by the Filer & Stowell Company, of Milwaukee, Wis., and the other three by The J. Morton Poole Company, of Wilmington, Del., and all were designed by the Edison General Electric Company. The cylinder dimensions are 16¼ x 23⅞ x 38½ by 30-inch stroke with 600 feet piston speed per minute, corresponding to 120 revolutions. All cylinders are steam-jacketed. All engines are designed to run at the normal speed of 120 revolutions, no matter how the load varies, this being accomplished by independent, automatic, centrifugal governors, fitted to each cylinder as in other high speed engines of the fly-wheel governor class. In this instance, however, they are contained in a disc bolted to the shaft. The three independent governors have proved their advantages in being able to keep the efficiency of the whole generating unit higher when operating light loads than when the governor was confined to the high pressure cylinder alone with the intermediate and low cylinders fixed, to say nothing of the advantage in having three independent governors guarding against any accident due to breakdowns. This is of great value, especially in railway plants.

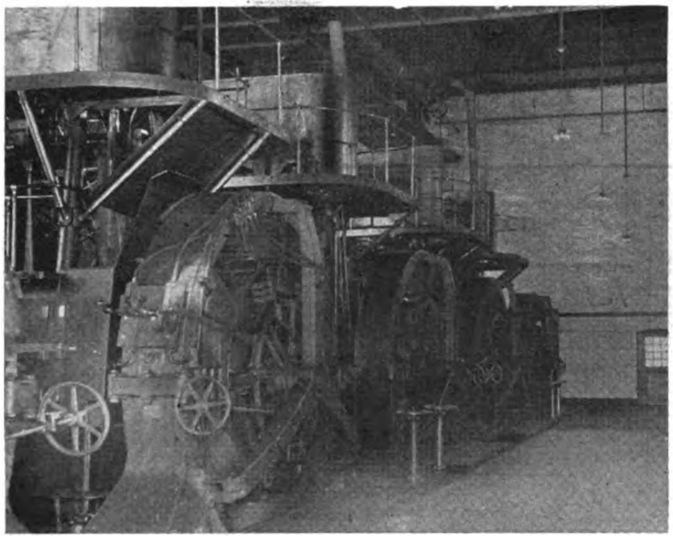


FIG. 6.—THE RAILWAY ENGINE ROOM.

The dynamos are of the well known multipolar Edison type with 6 magnet poles, ring wound armatures and commutators formed by the side of the armature winding. The six brushes are mounted upon a spider, which can be moved by a tangential screw into the proper position and all brushes may be simultaneously lifted from, or lowered upon the commutator. All the generators run very smoothly with no appreciable sparking at the brushes. They are compound wound and the standard of 500 volts is well maintained as the very slight variations of the voltmeter show. Measurements taken show the efficiency of these units to be 86 per cent. and the percentage is well kept up both on over-loads and extremely light loads.

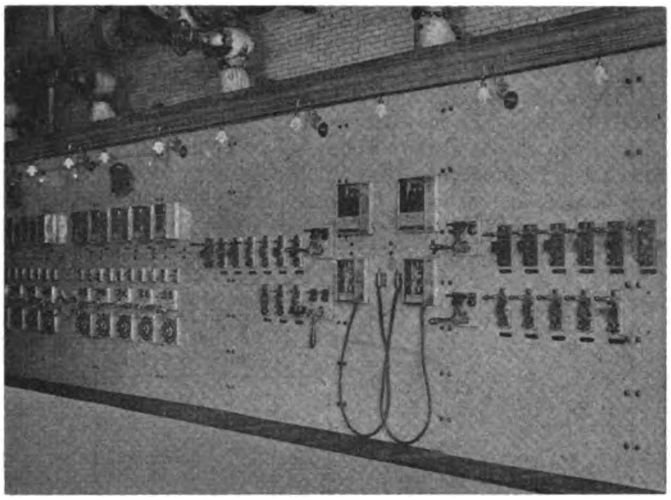

FIG. 8.—THE SWITCHBOARD.

Switch-board.—The switch-board, of white marble, measuring 72 feet in length by 10 feet in height, is placed along the south wall with convenient space left at the back for the cables and connections. It is divided into two distinct halves; the dynamo board and the feeder board. A switching diagram is shown in Fig. 7 and a view of the switch-board in Fig. 8. All the negative cables, passing through the large double pole switches on the dynamos, are connected to a common bar on the back of the board, communicating with a second bar in the basement from which the return-feeders start. All the intermediate cables from the positive brushes are similarly connected but without any switches; the positive cable from the end of the compound winding being joined to the common bar, passes a switch, ampere meter and a fuse on the switch-board. Beneath each set of this apparatus is the handle of the shunt regulator. Two differential galvanometers with sliding switches for parallel coupling and two large Weston station voltmeters complete the outfit.

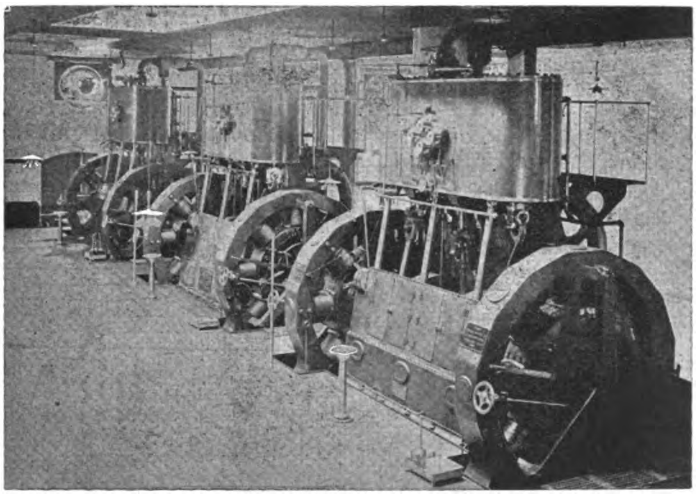

FIG. 9.—THE LIGHTING ENGINE ROOM.

From the positive bar the current passes through two amperemeters to four bars, which in case of emergency, can be interrupted by four heavy switches without causing too sudden a break of the full load. The feeders are led from the four bars, passing through a copper-wire fuse and a simple switch. To measure the current taken by each feeder, two amperemeters are provided, which can be switched on any of the feeder circuits by means of flexible cables and plugs. The fuses are made of copper wire, spirally wound to produce a strong magnetic field when a short circuit occurs. The arc formed by the fusing of the wire is blown out by the magnetism, and the destroying effects of the arc are thus prevented. The able electrician of the plant is the inventor of the simple device.

Electric Light Department.—The electric light department, Fig. 9, occupies nearly the whole upper floor with a free floor space of 95 by 84 feet. It is 20 feet high over the beams, but only 16 feet over the floor plates, 4 feet being reserved for piping and cable connections underneath. At present three engines of 300, and one of 150 h. p. are installed, and 12 additional 300 h. p. engines will complete the plant. The units are of the same type as the railway plant, the only difference being that the dynamos are shunt wound, operating at present at from 115 to 120 volts. Each unit is working directly on the three wire system.

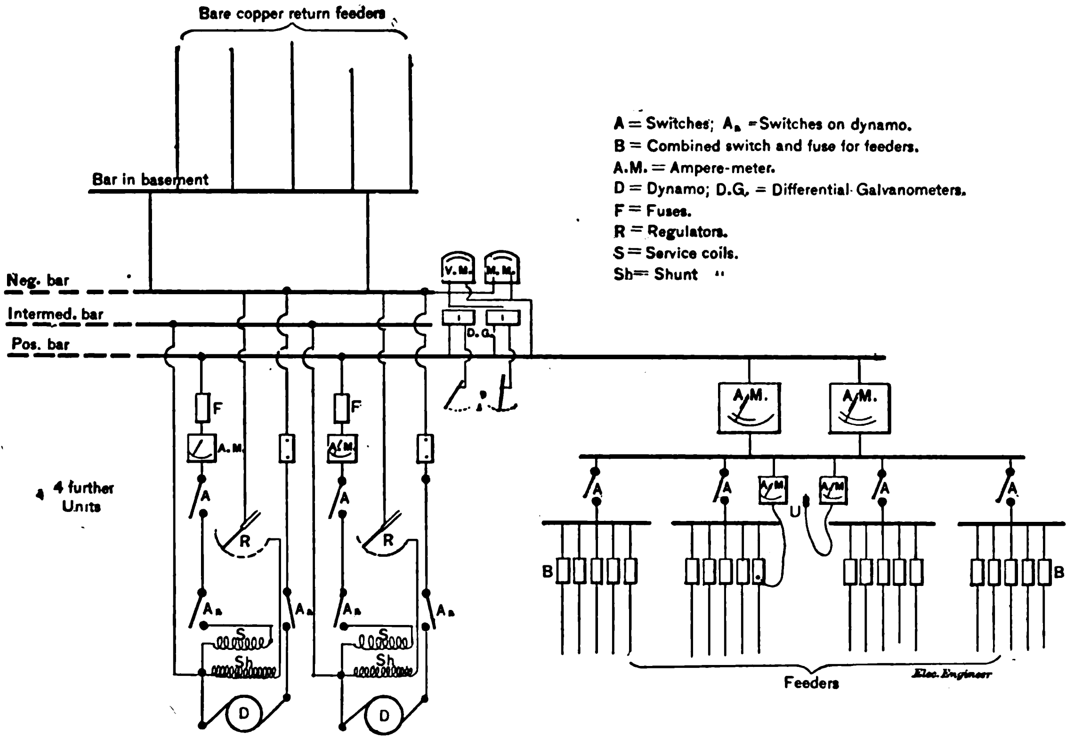

FIG. 7.—SWITCHBOARD CONNECTIONS FOR RAILWAY PLANT.

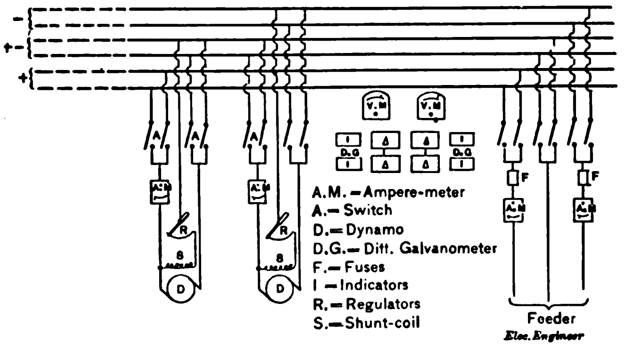

FIG. 10.—CONNECTIONS ON SWITCHBOARD.

The switchboards are placed around the east stack, and raised about five feet above the floor to give the attendant a good view of the whole room. The underground cables connect the dynamos with the board, where the current passes through an ampere meter and one double switch for each pole, Fig. 10. By means of these double switches and corresponding double bars it is possible to run dynamos at different voltages to suit the different losses in the feeders at heavy load. From the diagram Fig. 11, it will be understood how, with three dynamos, four different pressures can be obtained. This is necessary when operating outlying districts, although it may seldom be required.

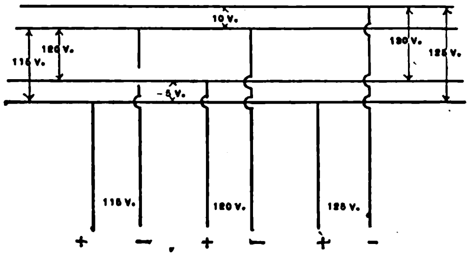

FIG. 11.

Efficiency of Plant.—Reliable measurements, giving exact figures as to the efficiency of the different parts of the plant, have not yet been made, but the results elsewhere obtained with the adopted types, give us an idea of what may be expected. To dwell on the boilers may not be necessary, as general experience has shown the Galloway boilers to be in every respect equal to the most efficient boilers in the market, and the arrangement and thorough protection of the steam piping excludes the possibility of any appreciable amount of loss by condensation.

Tests made in Milwaukee show an unusually high efficiency of engines and dynamos, and a very complete set of tests made in Boston on the same type of engine as used for the railway plant, confirms the results. Fig. 12 shows the I. H. P., commercial efficiency, and the steam consumption curves obtained in Boston as an average of a large number of readings. The efficiency of the unit was very high, giving in some cases, over 87 per cent., and on an average, at half load, 80.8 per cent. At three quarter load it gave 84 per cent. and so on, the steam consumption being very nearly that for which they were designed, *i. e.*, 15 pounds per I. H. P., showing on an average 18 pounds, between half load and full load. These figures indicate sufficiently the high degree of perfection of the generating units. It may be mentioned here that in the design it was intended to get the maximum efficiency curves of steam engine and electric generator to cross at the same point, that point being the longest duration of load. That decided upon was 80 per cent. of its normal capacity, and, considering that neither the engine nor the generator had at that time been constructed, the results are very good indeed.

Distributing System of Electric Light Plant.—The distribution of current is made on the three wire system, and all conductors are laid underground in Edison tubes. The diagram, Fig. 13, shows the extension of the mains and the points where the feeders are connected to them. Starting from the station are ten feeders, some of which are bifurcated, branching off to different points, and thus securing good equalization of pressure. The outer cross section of feeders and mains is given with the diagram. The section of the neutral wire is one third that of either of the outer ones in the case of feeders; in the mains all three wires have the same section. From each of the feeding points, seven wires, placed in the same tubes as the feeders, run back to the station, partly for purposes of testing and control, but mainly to regulate the pressure in the net-work.

The extension of the conductors from the station is remarkable, forming a net-work over one and one-quarter mile from the station. Up to the present time about 13,000 incandescent lamps of 16 c. p., 74 arcs, and 350 h. p. in motors, varying from ½ to 15 h. p. have been installed.

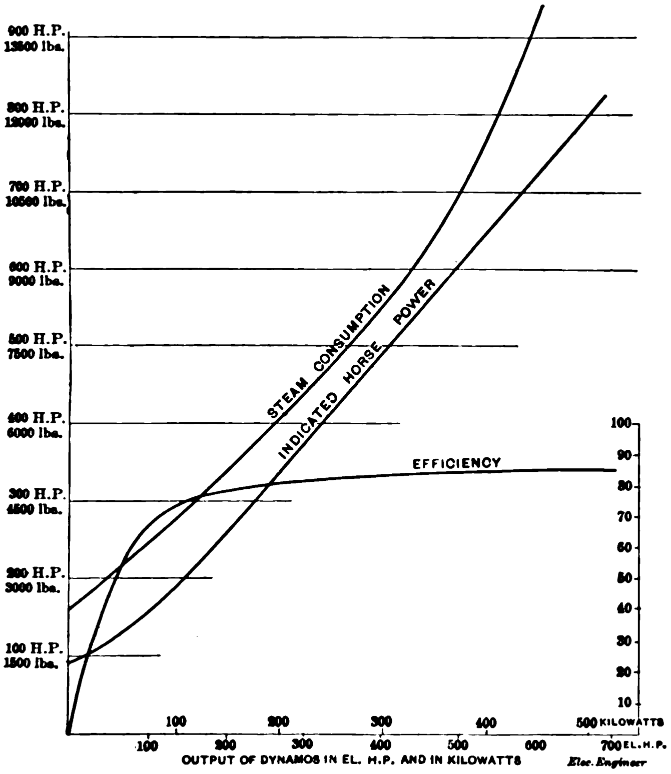

FIG. 12.

The comparatively small number of incandescent lamps in use as yet is doubtless due to the high price of one cent, as compared with gas, which is sold at half that price.

Motors and Meters.—Commercial power is also sold from the lighting conductors, and is used to a very large extent for operating elevators and other machinery, and in some cases draw bridges over the river. The amount of power at present supplied is about 400 h. p. Edison meters are used and give full satisfaction as to exactness, but the trouble involved in the weighing of the zincs seems to be a drawback. A very neat, well furnished meter-room with all necessary chemicals, balances and other instruments is placed near the office of the Edison Electric Illuminating Company.

A POOR QUARTER FOR WESTERN UNION.

The directors of the Western Union Telegraph Company met last week, and declared a quarterly dividend of 1¼ per cent.

The quarterly report presented is not very pleasing, showing, as it does, a deficit after paying the regular quarterly dividend of $378,737, as against a surplus last year of $229,288. The total surplus now amounts to $6,893,318. The earnings, $806,263, on the stock outstanding, $94,820,000, for the quarter were .85 of 1 per cent.

THE ANTWERP EXPOSITION.

THE Commissioners of the United States to the Antwerp International Exposition call the attention of manufacturers and producers to the fact that the exposition will open May 5. Applications for space and concessions should be made before April 1 at 14 Church street, this city. Low rates for shipments to the exposition have been obtained.

MR. GEORGE P. LOW, the electrical expert in insurance matters, has resigned his position as a member of the electrical engineering staff of the Midwinter Fair, and has been extremely busy catching up with arrears of his own immediate professional work.

DISTRIBUTING NIAGARA'S POWER THROUGHOUT NEW YORK STATE.

WHEN the project for utilizing the power of Niagara Falls for commercial purposes and distributing it electrically was broached, probably few, even among the most sanguine, in electrical circles, were hopeful enough to believe that the limits of distance to which the power would be transmitted would greatly exceed those which had already been shown to be practical; and indeed it seems to have been the general impression that the object of the Niagara promotors was to concentrate manufacturing interests at or near the Falls, electricity being adopted as the most feasible and economical method of supplying the necessary power. It has required but a short time, however, to bring out forcibly the fact that those interested in the Niagara project have looked farther ahead, and that their ideas of the limits of transmission are by no means confined to those of present practice, but, on the contrary, appear to range little short of the unlimited.

The first indication of the purpose of the company was shown in the experiments in electric canal boat propulsion undertaken late last fall near Rochester, and which were fully described in THE ELECTRICAL ENGINEER. These experiments, it will be remembered, were carried out with money appropriated by the State of New York for that purpose under the authority of Chap. 499 of the Laws of 1893. Section 1 of this Act authorizes the Superintendent of Public Works to designate some portion of the Erie Canal upon which these experiments could be made and to formulate rules for their conduct. Section 2 of this Act, however, reads as follows:

> **The Superintendent of Public Works, may from time to time authorize any person to construct, maintain and operate electric conductors for light, heat or power, upon or along any canals of the State or any portion thereof, upon such terms or conditions not inconsistent with the public use of such canals as he may impose; and in like manner he may contract for or permit the use of such light, heat or power upon any such canal; provided that he shall thereby create no charge against the State, except as against appropriations lawfully applicable to such purpose.**

Acting under the authority conferred by this clause Superintendent of Public Works, Mr. Hannan, has just concluded a contract with the Cataract General Electric Co., conferring upon it the right to enter upon all canal lands of the State for the purpose of constructing either on or over or under either canal bank a system for propelling canal boats by electricity, without interfering with the present method of operation. Central power houses may be erected for this purpose. The rates for towage are subject to modification and review by the State Superintendent of Public Works, but such rate shall not exceed $20 per electrical horse power for any season of navigation.

An important provision is that the company may, so long as the wants of the canal are supplied, employ its electric plant along the line of the canal in furnishing electric light, heat, and power for distribution to any point or points beyond the line of the canal, and thus may furnish electricity for lighting and power purposes in all of the cities and villages along the canal. The company is to furnish the State, free of charge, sufficient power to operate motors to open all gateways leading to and from locks, and also electric lights sufficient to properly illuminate such locks at night.

The company must have its plant for operating boats by electricity in operation on the Erie Canal between Buffalo and Albany within three years from date, or else the privilege accorded by the permit will be forfeited. In case the company shall construct along the canals an electrical plant for use such as the trolley system, it shall be the privilege of the State to condemn and purchase such property at a price equal to the actual original cost, with 10 per cent. added thereto.

The far reaching nature and the possible effects of the rights thus granted have naturally aroused animated discussion, and much adverse comment has been heard on the action of Superintendent Hannan. Indeed on the very day that the contract was signed a bill to repeal Chapter 499, above quoted, was before the New York Assembly, which has since been passed in that body and has already been favorably reported to the Senate, so that there is little doubt of its passage in that body also. In the mean time the promotors of the enterprise with the contract in their possession propose to get to work in order to show their good faith in the matter.

It must be evident that the part which electric canal boat propulsion will ultimately play in this undertaking sinks into comparative insignificance as compared with the broad field opened for furnishing power to the cities adjacent to the canal. These embrace the largest and most important towns in the State of New York, and we need only mention such cities as Buffalo, Rochester, Syracuse, Schenectady and Albany to indicate the scope of the field. Nearly all, if not all, the cities through which the canal runs have electric central stations and speculation is already rife as to the probable effect of the appearance of so powerful a rival in the field. Nothing definite is yet known as to the plans of the Cataract Company, but an outcry has already been raised that the local electric companies will be at its mercy if those companies do not accede to its demands. It is evident that if the Cataract Company can furnish power at any considerably less cost than it can be generated locally, two methods are open to it: It can either contract to furnish the local company with power to drive its machinery or transform, as it pleases, and not in anyway interfere with the business of local distribution; or, it can go into the business of local distribution itself as a direct competitor. We would consider the adoption of the latter plan most unfortunate for reasons which are not difficult to discern. Its consummation would mean the practical ruin of companies which have been built up by years of toil and the expenditure of many hundreds of thousands of dollars and many of which have but recently begun to enjoy the benefits of their early enterprise. To deprive them of these benefits now would be working a hardship which no fair minded person would countenance. But if, on the other hand, the Cataract Company, or its sub-company, the Niagara Falls Power Co., have in view solely the furnishing of power to local companies at rates cheaper than those companies can produce it themselves, then the enterprise is deserving of all the encouragement which can be given to it.

All these speculations and fears are based, of course, on the supposition that electric power *can* be transmitted cheaper from Niagara Falls than generated locally along the line of the Erie Canal. Without desiring in any way to dampen the ardor of the promotors or friends of the transmission scheme—and none can wish it greater success than ourselves—we are forced to confess that with our existing knowledge and experience, the scheme, in order to prove successful, will require heroic treatment.

Of course, we have the Frankfort-Lauffen experiments to fall back on; but while they give some indication they can not be considered in any way conclusive, as the actual power transmitted was but a trifle compared with that contemplated in the present instance, and experience has but too well shown the difference in the disruptive strength of insulating materials and the action of circuits when the high potential has a heavy current back of it. We must also bear in mind that the companies situated along the Erie Canal are very favorably located for obtaining coal cheaply.

We shall hail with delight any method that will enable electric current to be distributed at a lower cost than it can be supplied to-day and hence await with no little interest the promulgation of the details by which it is hoped to accomplish this with Niagara as the original source.

ELECTRIC COOLING AND HEATING.

THE lengthening days and a March of unusual mildness remind us that Spring is at hand, with its demand for electric service of a kind that has not been needed during the winter months. Hitherto that service has taken the shape of cooling and ventilation, and the market for electric fans has become one of no small magnitude. Even now active preparations are being made for the spring trade, and it is safe to assume that the coming summer will see more electric fans at work than ever before. The old ones are furbished up from season to season, and even the inefficient types are kept in use, the customer having rarely got it through his head that, as with a low efficiency lamp, what he saves in cost of apparatus is wasted in undue consumption of current; while newer forms, with novel adjustments, continually make their appearance.

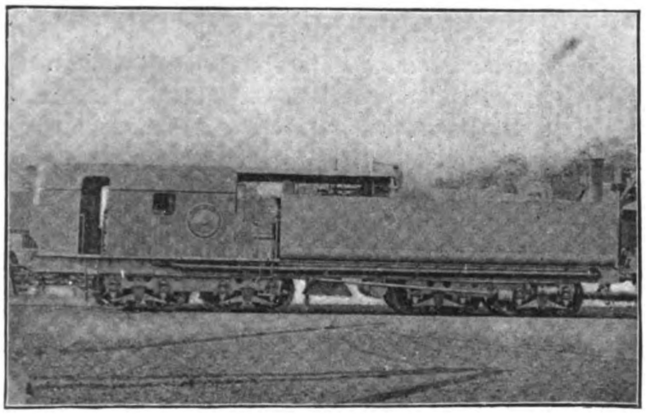
But the period in the development of electric arts has arrived when it is the duty of the central station manager to give his attention as much to electric heating and cooking as to electric cooling and ventilation. It is a fact that apparatus for cooking is now obtainable that people can use with economy and satisfaction. We could mention cities in which several residences have been fitted up with a plain ordinary kitchen outfit, and where the results are admirable. It is a mistake for a local company to view this new department of possible business with suspicion or prejudice any longer. In doing so, it makes once more the mistake that the gas companies made as to gas stoves, etc.; although at the present time gas companies have not only seen their error but have even gone so far as to sell gas stoves, etc., at bare cost, merely to induce the consumption of their product. This is the true lesson for central stations. What they need more than anything else is a day service and a flat load line, and to this end, electric cooking and heating apparatus may be applied with notable success. A local company that is making a canvass of its field this spring for fan and power work generally, may just as well include cooking, etc., in its survey. In most houses and apartments during the summer, the old cooking apparatus adds greatly to the discomfort caused by the weather; and wherever current is available electrical apparatus should find a hearty welcome. But the local companies must work with, and encourage by their orders, the manufacturers of such utensils and appliances. Let them keep sets on view at their offices; let them organize little exhibitions to show what can be done; let them reach out to the public through the local newspapers; let them employ every means of rendering such novelties familiar and popular. The results on the station output will be gratifying, and the summer earnings can be made in such ways just as heavy and profitable as those of the winter months.

ELECTRIC TRANSPORTATION DEPARTMENT.

TRIAL OF THE HEILMANN ELECTRIC LOCOMOTIVE.

In our issue of May 17, 1893, we gave a description of the electric locomotive design by Mr. J. J. Heilmann, of Paris, in which a most novel method of operation was carried out. This locomotive it will be remembered, derived its power from motors mounted directly on the axles and driven by current generated on the locomotive itself which contained a boiler and compound horizontal engine directly connected to a six-pole 800 h. p. generator. During the last few weeks this locomotive has been subjected to a series of official trials by the engineers of the Western Railway Co., of France, on a section of line between Havre and Beuzeville. Besides taking complete readings with the dynamometer car, apparatus was distributed along the line to measure and record automatically the deflection of the rail during the passage of the engine. A correspondent who was present during the trials furnishes us with the following interesting particulars of the results obtained.

The Western Railway Co. furnished a train of the same composition as their Paris express trains, but limited the speed strictly to 100 k. m. (62½ miles) per hour. However, when the Western Railway people convinced themselves that the engine ran with phenomenal smoothness at 95 k. m., on a very bad piece of track, (one could write with perfect ease at this speed when standing on the foot plate) and that the rail deflection indicators showed that the deflections were much less than with their regular express engines, they allowed the speed to be raised to 118 k. m. (74 miles) per hour, always with the same result. The general impression of the railway people present seemed to be that the scheme was a success, and that it would lead to the construction of much more powerful engines so that heavier trains could be hauled at higher speeds and with greater safety than with the present types. In fact, designs are now being prepared for a locomotive capable of developing 1200 h. p. normally, and with a maximum capacity of 1500 h. p.



THE HEILMANN ELECTRIC LOCOMOTIVE.

The great bugbear with this system so far has been the supposed losses by transformation of power into electricity and the transformation back again. But tests were also made of the consumption of coal with the electric locomotive and this compared with the coal consumption on express engines on the same line doing the same work. The results showed about 20 per cent. in favor of the Heilmann locomotive. The loss of power by the various transformations is thus shown to be less than the friction occasioned by the transmission by cranks and connecting rods.

The friction of the electric locomotive was even less than anticipated. Thus the Heilmann locomotive would not stand on a grade of 3.4 per cent. without applying the brakes. On a down grade of .8 per cent. the locomotive obtained a speed of 95 k. m. without any help from the engine, steam being entirely cut off. One of the express engines of the Western Railway will not go down this grade without the aid of steam, the resistance of engine and tender being more than 10 k. g. per ton, whereas the resistance of the electric locomotive is less than 3.4 k. g. per ton.

Of course in such a complicated machine, it was expected that some defects would crop up, chiefly in details, mostly the consequence of bad work, things which will be easily remedied and which do not concern the general features of the machine.

THE WINNIPEG, Canada, electric street railway is now carrying passengers at the rate of two cents.

THE WHITE-CROSBY CO.

THE firm of J. G. White & Co. of this city, which has done so much of the heavier electric railway work in American cities, is to enjoy a most important accession to its ranks on May 1, when it will be joined by Mr. Oscar T. Crosby, so long the mainspring of the Railway Department of the General Electric Co. The organization of the new company, to be known as the White-Crosby Co., is rather for convenience than anything else, as these two engineers will practically operate as partners. The fact of Mr. Crosby's resignation has been known to his personal friends and intimates for some months, but he has found it by no means easy to relinquish work to which he has devoted such close and unremitting attention; and hence he has preferred that nothing should be said on the subject till he could actually "clean up his desk." The change is made with the utmost harmony and cordiality still existing between him and his old coworkers in the General Electric Co. Those who know Mr. Crosby are not surprised, however, that he should prefer to work independently rather than for a large corporation, and that for professional motives he should free himself from the entanglement of so much laborious work of a commercial nature. It is to be hoped that a fitting occasion will shortly present itself for signalizing this important step on the part of one who has endeavored so successfully to promote the electric railway art, and who from first to last has stood for sound engineering, scientific methods and a progressive, impartial spirit of inquiry as to what is fittest and best in dealing with each new problem as it arises.

THE HESTONVILLE, MANTUA & FAIRMOUNT TROLLEY ROAD, PHILADELPHIA.

WE learn from Mr. A. Langstaff Johnston, C.E., E.E., the chief engineer of the road, that the contracts are about to be given out for a large part of the work on the Hestonville, Mantua and Fairmount line. The power station will be erected at Twenty-sixth and Callowhill streets, Philadelphia, Pa., on the Schuylkill river, occupying part of the property used by the Race and Vine streets line for a depot and stable. It will have the advantage of easy delivery of coal from boats. The station will be of stone and Pompeiian brick, one story in height, and of attractive appearance.

It will have a capacity of 2,000 horse power, and, if more is needed in the future, the capacity can be doubled by extending the station on the company's property. The equipment will consist of four cross-compounded engines of 500 horse power each, belted to the same number of 400 kilowatt generators. Eight boilers, each of 250 horse power, will make the steam, and there will also be the usual auxiliary machinery, switchboard and safety devices.

ELECTRICAL LAUNCHES IN VENICE.

IN the account of the placing on the Canals of Venice, of one of the electric launches employed on the lagoons at the World's Fair we omitted to mention that the launch was taken over from this country and put in complete operation by Mr. H. S. Lathrop, who was attached to the launch service at Chicago. Mr. Lathrop has just returned from Italy and speaks quite hopefully of the prospects of electric navigation in Venice.

TO ELECTRIFY BROOKLYN BRIDGE.

Proposals will be received by C. C. Martin, Chief Engineer and Superintendent of the New York and Brooklyn Bridge, at his office, 179 Washington street, Brooklyn, N. Y., until April 5th, 1894, for plans, specifications and estimates for lighting the Bridge Cars by Electricity; also for heating them, also for propelling them.

ELECTRIC LINE FOR NORTH CHICAGO.—The ordinance authorizing the North Chicago Electric Railway Co. to extend its lines in the north division of the city and connect with the cable lines of the North Chicago Railway Co. was called up in the city council on February 26. After considerable discussion about a proposition, permitting the charging of double fares north of Belmont Ave., the ordinance was passed by an almost unanimous vote. At the same meeting an ordinance for an electric street railway, to be operated by the storage battery system, from Franklin street along Southport avenue to the northern limits of the city, was introduced and referred to the Committee on Streets and Alleys north.

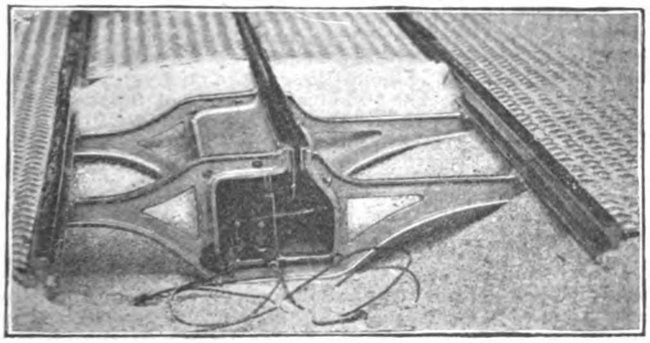
THE PETERSEN CONDUIT RAILWAY SYSTEM.

A WORKING model of an underground conduit system for the propulsion of street railway cars which is the invention of Mr. H. Petersen, proprietor of the Petersen Electrical Works, of Milwaukee, Wis., has been on private exhibition in New York city, and has attracted much attention, and elicited much favorable criticism.

In the construction of underground conduits for electric railway conductors or wires, suitable provision against the accumulation of moisture or dirt within the conduit containing the conductors, has often been ignored, as well as the prevention of condensation of moisture from the atmosphere upon the walls of the conduit and the insulation, which causes frequent short-circuiting or grounding of the current and losses all along the line by leakage.

The principal object of the Petersen system is to provide an underground conduit of such construction as to effectually guard against the admission of moisture to that portion of the conduit occupied by the conductors, and to prevent the condensation of moisture on the walls or the conductors or their insulating supports. It also provides for the ready removal of any dirt which may find its way through the slot, and means for maintaining a circulation of dry, cold air within the part of the conduit in which the conductors are located.

In the accompanying illustration it will be seen that the entire conduit is divided into two longitudinal passages or compartments. The slot in the top of the casing, for the admission of the contact-carrying device, communicates with one compartment of the conduit, which is arranged to communicate at intervals with a sewer, so that any accumulation of dirt or water which comes through the slot may readily pass off. The compartment in which the conductors are located communicates with the compartment in which the slot is formed by means of longitudinal openings which are ordinarily kept closed by a movable closing device engaged by the contact-carrying arm as the car advances. This opens just sufficiently to permit the passage of the arm and closes immediately after the arm has passed. A steel broom is attached to the car and arranged to extend into the slot compartment and to sweep any dirt that enters this compartment to the sewer connections.



THE PETERSEN RAILWAY CONDUIT.

The compartment in which the conductors are located is out of line with the slot so that any water which may drip from the sides of the slot will fall clear of the wall of this compartment and also of the closing device and the slot rail is extended down at the side of the slot next to the compartment containing the conductors far enough to carry any water which enters the slot down past the opening into the latter compartment. Condensation of moisture on the walls of the conductor compartment or upon the conductors themselves or their insulated supports is prevented by the circulation of air maintained by the running of the cars, the contact carriers forming currents which, under ordinary circumstances, will, it is claimed, be sufficient to keep this compartment and the conductors perfectly dry. In a very wet climate, if found necessary, a circulation of air may be supplied to this compartment by means of a fan, but under most circumstances the inventor believes that this would not be required.

Instead of trolley wires this system employs iron or steel contact rails of considerable sectional area, as shown, divided into sections of about 100 feet in length. Each section of the contact rails is connected with the two main feeders and provided with a switch and a safety cutout device placed in the manhole, so that in case of trouble upon any particular section the contact rails where it occurs can be switched off without interfering with traffic on the rest of the line. By means of the safety cutout in case of an accidental short-circuit, the fuse will blow and thus cut out the section automatically.

The contact rails are supported upon two brackets and securely held in position by a strong insulating material, and the whole compartment is coated on the inside with a waterproof insulating paint. The main feeders are laid in metal pipes thoroughly insulated.

The contact carrier has an arm arranged to extend through the slot and provided with a lateral bend which brings its lower end into the compartment containing the conductors. This arm is provided with two contact shoes so arranged as to embrace and retain the upper part of the contact rails, and provided with swivel joints to compensate for any unevenness, and springs to keep the shoes in proper contact with the conductors. The shoes are so constructed that the car may run back and forth without making any change in their adjustment. The contact carrier arm is provided with joints permitting a motion of the arm in any direction and springs serve to hold it in its proper position while at the same time allowing it to yield freely in either direction without straining any of the parts. The contact carrier is provided with lever mechanism by means of which the motor man upon the platform may lift it out of the conduit at a manhole without delaying the car more than a few seconds.

With this system, the same cars that are used on overhead trolley systems may be employed by the simple addition of the contact carrier arm which enters the slot. This arrangement is to provide for systems where an underground conduit will be required for part of the line running through a central part of a city and where overhead wires may be used in the suburbs. The contact carrier is simply lifted from the conduit at the last manhole and held up underneath the car, while the overhead trolley is brought into use.

By this system any form of cable conduit may be utilized for the underground conductors, it being simply necessary to insert and fasten in place the partitions and the movable closing devices and to place the conductors and feeders in position.

MISCELLANEOUS.

COAL CONSUMPTION IN GENERATING ELECTRICITY.

BY

J. Stanford Brown.

IN THE ELECTRICAL ENGINEER (p. 200; p. 205 discussion and p. 206 editorial) of March 7, is given the report of The National Electric Light Association's "Committee on Data" on the above subject. The basis of comparison is a table which the Committee has drawn up showing the watt-hours per pound of coal which will be developed from a given number of pounds of coal per indicated horse-power when the engine and dynamo each have an efficiency of 90 per cent. So far so good. But does this standard reach a basis from which absolute comparison can be made?

The Committee in starting from a basis of the coal required per hour per indicated horse-power have really been starting with the coal consumed under the boiler, and stated the efficiency of the boiler in a roundabout way instead of as a percentage efficiency which they have done with engine and dynamo. Such being the case, why not assume an efficiency for the boiler and then go right back to the heat units per ton of coal burned, which must ultimately be the only standard for universal comparison? And here it is necessary that the calorific value of the coal be known. In other words with any given plant of boilers, engines, generators and wiring, the watt-hours per pound of coal will vary with the quality of the coal.

And this is perhaps one of the weakest point in central station supervision as now exercised. Too many managers do not know, nor do they usually make any attempt to find out, what calorific value their coal has. Attention has been called to the point frequently. In fact, a recent paper has stated that in a certain station in Chicago (?) the coal was paid for, not by the ton, but by the pounds of water evaporated from it.

In THE ELECTRICAL ENGINEER of March 7, 1894, p. 197, W. S. Hadaway, Jr., in an article entitled "Electric Heating and its Relation to Central Station Work," says: "A well designed central station of moderate size produces a h. p. hour by the combustion of about 3 lbs. of good coal. The electrical h. p. hour developed by this coal has 2,565 heat units; we have to balance these 2,565 heat units in the concentrated form against 42,000 heat units existent in the three pounds of coal in a more diffused state."

The subject is brought forward now, not with any idea of criticising the work of the N. E. L. A. Committee, for which all interested in central station management must be most grateful, but simply to suggest that it might be just as well to proceed at once. to what it would seem must become the only ultimate standard of comparison, in trying to find how many watt-hours can be got from any given number of B. T. Units potential in the coal pile, and one is entirely at sea with the coal table referred to above *until the number of heat units in a standard (?) pound of coal is settled.*

POLYPHASE TRANSMISSION.—II.

BY CHARLES F. SCOTT.

(Concluded.)

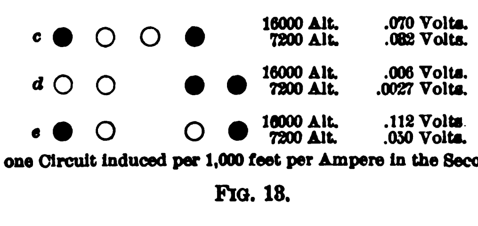
MUTUAL INDUCTION.

If two circuits be run on the same pole line they act as a transformer in which one circuit carrying current may act as a primary and induce E. M. F. in the other as a secondary. If the latter circuit is connected with the same dynamo and is delivering current, its E. M. F. will be slightly raised or slightly lowered by the effects of the first circuit. Conversely, the second circuit will have a similar effect upon its neighbor, raising or lowering its pressure by a slight amount. If the two circuits be connected to different dynamos which are running at slightly different speeds, then the E. M. F. induced by one circuit upon the other will sometimes increase and at other times decrease the E. M. F. of the circuit, depending upon whether the two currents at a given moment are flowing in the same or in opposite directions. This fluctuation may cause variations in the intensity of the lights supplied. It is readily detected in the service of some central stations, and is of course more marked at time of full load, as the induction of one circuit upon another depends upon the strength of current carried. The fluctuation due to this action may be readily distinguished from that due to the slipping of belts or irregularity in engine speed, as the induction effect is due to the difference in alternations between two machines, and the speeds of the two machines are apt to vary slightly from time to time, giving a gradual variation in the rate of fluctuation of the lamps. The fluctuation due to mutual induction of lines occurs only at the end of the line and is not observed in the station, while the other causes affect the station lights also. The number of volts E. M. F. set up in one circuit by a parallel circuit depends upon the current, the distance which the lines are parallel and upon the relative positions of the four conductors. The distance between wires may be six inches or six feet without affecting the mutual induction, provided the relative positions be unchanged. Several dispositions of circuits are shown in the diagrams, Fig. 13, and the number of volts per thousand feet at 7,200 and at 16,000 alternations, which are induced in either circuit by one ampere in the other, are given in connection with each diagram. The number of volts required for producing objectionable flickering in the light depends upon the voltage of the lamps in service, the efficiency at which they are run and the general surroundings in which they are placed, notably the relation of lamps to reflectors, white walls, etc., and the general disposition of the customer.

An E. M. F. of ½ per cent. induced in one circuit by another can in some cases be detected, and usually more than one or two per cent. will cause objectionable flickering.

METHODS OF REDUCING MUTUAL INDUCTION AND SELF-INDUCTION.

The mutual induction is reduced by bringing the wires in each circuit close together and separating the circuits. The effect of this mutual induction may be neutralized by crossing one of the lines at its middle point so that induction in the first half of the line is counteracted by the induction in the second half. It is readily noted that the effect of self-induction in a circuit is reduced as the wires are brought close together or if each conductor be divided into several wires in multiple and separated. The effect of self-induction is diminished as the number of alternations is reduced. The following points are also to be noted in connection with inductive drop. If the power factor be nearly 100 per cent. the inductive drop increases as the square of the counter E. M. F. If the E. M. F. of the circuit be increased and the same power be delivered over the same circuit, the per cent. counter E. M. F. decreases as the square of the E. M. F. delivered, and the inductive drop decreases approximately as the fourth power. If the number of alternations be decreased the counter E. M. F. decreases directly and the inductive drop decreases as the square. The inductive drop at 7,200 alternations is less than one-fourth of that for 16,000 alternations for ordinary power factors.



Volts in one Circuit induced per 1,000 feet per Ampere in the Second Circuit.

FIG. 13.

CAPACITY IN LINES.

The static capacity in ordinary lines is usually small and its effect is not of importance unless the line be very long or the pressure be very high. The general effect of capacity in the line, or of connecting condensers to the line, is to lessen the current from the generator which is required for supplying inductive load and to reduce the drop due to self-induction. The use of condensers for this purpose may lead to very considerable gains in circuits where the self-induction of line or of load becomes considerable. If an induction circuit or transformer supply current to condensers the E. M. F. may increase instead of decreasing as it does with inductive load.

POLYPHASE CIRCUITS.

The subjects which have so far been considered apply to single-phase as well as to polyphase circuits. The effects of self-induction will be brought to the attention of the electrical engineer much more prominently in connection with polyphase work, however, because larger alternating current enterprises will be carried out with the polyphase system and power work involving variable power factors will be a large element in this system. There are, in addition, several problems which relate distinctively to polyphase working. One of these is the most suitable number of phases to be used. The two-phase system and the three-phase system are both in operation, and, while it is admitted by the adherents of each system that there is no fundamental difference between them, yet each has specific characteristics giving particular advantages.
